The greenhouse, a very old structure, is undergoing repairs, and the last vestige of flues in it is being swept away, buried where rubbish always was. It really is astonishing to see how good the woodwork of this house is, and the glass so clear, considering that it is about forty years old. The house is 24 feet by 15, and a lean-to.

Against the north wall a glass lean-to has been erected recently, which is to be devoted to the growth of Peaches, Nectarines, and Plums of the choicest kinds that can be had. The length of this house is 300 feet. The roof has a rapid fall or high pitch, short lights in front which open, and about 1 foot of the top opens also the entire length, these lights being shut or opened easily by levers and cranks. It has two four-inch pipes along the front, and the glass is put in in large squares. I understand the cost of a house of this description is about £1 per foot, exclusive of the pipes.

In the centre of the garden stands Mr. Waterhouse's observatory. He was formerly very partial to astronomical studies. He has kept a rain-gauge for nearly forty years, and is one of those who delight in seeing and enjoying an interesting garden, and whilst doing so is not backward in permitting others to view his, in proof of which I may state that his grounds were open to the visitors of the recent flower show at Halifax.

In conclusion, allow me to say that all I saw was very praiseworthy, and highly creditable to Mr. Baynes and his assistants, to whom I tender my hearty thanks for his cordiality, and not less his hospitality; and with a shake of the hand I bade farewell to him and left one of the most interesting gardens in the county of York.—G. A.

TRANSATLANTIC KITCHEN-GARDENING.

Nor the least part of a true gardener's professional enjoyment is the pleasure (albeit plentifully seasoned with a due mixture of mental anxiety), of getting in his spring crops as safely and speedily as possible; and here where we are of necessity almost entirely confined to in-door operations from November till March, the change is all the more agreeable and exhilarating when we can put a spade in the ground, and have the earlier crops fairly under weigh. Spring, strictly speaking, is of very short duration here, as we are launched from the rigour of winter almost right into the heat of summer with very little intervening preparation. As an instance of the rapidity of the change, I find on reference to notes taken at the time, that on the 10th of April last year we had a heavy fall of snow with a corresponding temperature, and on the 18th of the same month (Good Friday), the thermometer indicated 88° in the shade, with a cloudless azure sky. This rapid change has, of course, a corresponding effect on vegetation, necessitates an energetic concentration both of head and hand work, and very speedily rubs off any rust that may have accumulated about the mental faculties during the long winter months. I was much struck with the truthfulness of a motto I can well remember reading in the rooms of the late Albert Smith, Piccadilly—viz., "Rubs make men and gems bright," from whence the inference may very readily be drawn, that as gardeners in pursuit of their legitimate calling meet occasionally with some pretty hard rubs, this may account in a great measure for the honourable position horticulture at present occupies, and for the superior intelligence that is to be found amongst those who devote their best energies to the elevation of the science of gardening; but at the same time it must be borne in mind, that there must be something of

the gem in the man to begin with, else no amount of rubbing will brighten up general opacity.

The gardeners of America exhibit a most praiseworthy perseverance and practical ingenuity in contending against and overcoming difficulties incidental to climatic extremes, with rapid and very often violent atmospheric changes; but most of those holding good situations here have learnt the rudiments at least of their profession, in some part of the British Isles. The old and oft-quoted adage, "That it never rains but it pours," though generally applied allegorically, is literally true here, for without any preparatory Scotch mist, down the water comes in torrents, often doing sad mischief, and leaving the ground when dried like well-baked pie-crust. In consequence of this feature, besides being the better practice under any circumstances, cropping is almost invariably done in rows, so as to admit of a liberal application of the Dutch hoe to break the crust.

As the ground is often frozen to the depth of 18 and 20 inches, very little kitchen-garden work can be done before the last week in March, and in late seasons not before the first week in April, when the first crop of Peas is sown. Of these, successions are sown up to the first week in June; after that time it is of little use to sow them, as they are almost sure to be destroyed by mildew; from the succession sown on the 7th of June last year, from this cause I could not pick a dish fit for table. Cauliflowers, with the exception of an early crop on a hotbed, are a very precarious vegetable, the hot weather generally coming in too soon for them, and if combined with a spell of dry weather causing a general inclination to "button," a most provoking consummation to a sanguine gardener's hopes. Young Beets are highly relished as a dish, and by a little management may be supplied from the 1st of May till November, when they are lifted and stowed away for winter use in the regular orthodox manner. The Bassano, Blood Turnip, and Henderson's Pine Apple Beet are the most useful varieties for summer; and the Long Blood Red for winter use. But the most indispensable vegetable in an American kitchen garden is the Tomato; and whether it is owing to the climate adapting the system to relish it, or the juices of the fruit being more highly perfected by a tropical temperature, I can testify from personal experience, that there is no more desirable addition to a repast during the continuance of the hot weather than the Tomato, and previous to coming to America I could not endure even the smell of them. They are highly relished both by rich and poor, are sent to table both raw and cooked, besides making excellent preserves and ketchup. The seed is sown in heat in February, and by the middle of May there are fine strong plants for planting out, which is done in rows 4 feet apart each way. They require very little more attention except keeping the ground clean, and a little judicious thinning if the plants grow too rank.

We have an improved substitute for the Windsor in the Lima Bean (substitutes are at a premium just now), and an excellent vegetable it is. Hills are prepared 4 feet apart each way, with a pole from 10 to 15 feet high in the centre of each, five or six Beans are then planted round the bottom of the pole about the middle of May, and in a short time this part of the garden looks like a miniature Hop field, for the Lima is a great runner—indeed, a gardening friend averred that were they supplied with a pole 50 feet high he believed they would reach the top of it by the end of the season; but this I cannot vouch for, nor is it desirable they should reach such an altitude, else the task of gathering a dish would be no sinecure. Should a cold rain occur just after planting, the Bean is almost sure to burst and rot in the ground, and as only one planting can be made, considerable judgment is required to get them evenly above ground.

Kidney or string Beans are also grown extensively, and in September and October last year, I had a fine crop grown from seed saved from the spring sowing—an instance of advantages sometimes to be derived from climate.

Sweet Corn must also be supplied daily from July to October, and forms a most agreeable addition to the dinner-table. This is an improved variety of the Indian Corn, and it is surprising how quickly it degenerates if a field of corn be in close proximity to that part of the garden where it is planted. Sweet Corn is generally planted in hills 3 feet apart, successional crops being put in from May to July,

thinning out to three plants in each hill, and earthing-up as the plants grow strong enough; and it is better to strip off all superfluous side shoots, as it promotes the growth of the plant and the size and quality of the Corn. After a warm shower in June or July the Corn grows very rapidly, and when fully developed attains the height of 5 and 6 feet.

A large purple variety of the Egg-plant is another culinary curiosity. The seed is sown on a hotbed, or in an early grapy if that is available, in February, grown on in pots, then transplanted to the open ground by the end of May, in rows 3 feet apart, and by the end of August the fruit are ready for cooking.

Celery is sown in a favourable situation in rows in April, and then planted out in July, on the two-fold system of single rows, and a bed planted in rows; for this two-fold reason—the single rows are lifted by the end of October, carefully and tightly packed upright in trenches 3 feet deep, then covered over with leaves or straw for daily use throughout the winter, the bed being earthed over to the depth of 2 or 3 feet, and opened in early spring when that in the trenches has given out. The bed becomes, of course, one frozen mass, and the task of unearthing is, therefore, no easy one.

Pumpkins and Squashes are also grown in great variety; but the really useful sorts for a garden are limited to a few. Amongst Squashes, the Early White Bush for summer, and the Boston Marrow for fall use are the best. This can be planted with economical advantage betwixt the rows of Sweet Corn, and soon covers the ground when the Corn is cleared away. The Cheese Pumpkin, so called from its shape, is the most useful variety in its class, and can be used in various ways. From it is made the Pumpkin-pie so much and justly prized in every American household, likewise a first-class preserve, and last year I tasted an excellent jelly as clear as the finest White Currant, extracted from it by a neighbouring gardener's wife, so that British housewives may see that their American sisters are in no ways behindhand in this very useful department of domestic economy. The Mammoth Pumpkin is often grown to a great size, but is only fit to look at. There was one exhibited last year weighing 264 lbs., at the office of the "American Agriculturist," New York, where throughout the year there is generally some curiosity or monstrosity of the vegetable kingdom to be seen.

Melons are most admirably adapted to this climate, and do not require a tithe of the trouble requisite to their successful cultivation at home; but instead of one or two being sent in occasionally, they must be supplied in quantity every day during their season. They are divided into two distinct classes, Musk and Water Melons, each class having again its varieties more or less excellent. The Musk Melon has an entire cordate leaf, the well-netted fruit resembling the finer varieties of the Trentham Hybrids. The Water Melon has a more divided leaf, the fruit oblong-shaped, sometimes attaining the weight of 40 lbs.; size an indication of excellence; skin smooth and dark green, the edible part when fully ripe resembling frosted work of a deep pinkish colour, and most deliciously cool when the thermometer is over 90°, as it has been every day for the last three weeks, and seldom below 85° at night. Melons are sometimes sown in pots to forward them a little, but I question if anything is gained by this. The most generally adopted system is, to plant them in hills 7 feet apart in well-prepared ground, the hills being covered with small hand-lights until two or three rough leaves are formed, when the plants will thrive better by being uncovered. After this they only require a little thinning and stopping. From forty to fifty hills with—say, four plants in each, afford a good supply to a moderate-sized family.

Okra is sown in rows 4 feet apart, and is used when in a young state for making a peculiar kind of soup called "gombo."

Citrons are treated the same as Melons, and are extensively used as a preserve.

The Sweet Potato is sometimes grown here, but more for experiment than profit, as the cool evenings in the early fall are apt to prevent it from properly maturing; but it is a most delicious vegetable when properly cooked. An American Potato, the Peach-blossom, received very favourable notice at Kensington Gore last year, which it well merited;

besides other good qualities it is an excellent keeper through the winter.

A gardener here has many insidious and destructive enemies in the insect world to contend against, most vegetables and fruit having an insect peculiar to that variety, and some are favoured by the attentions of two or three. One of the most destructive is the Asparagus bug, which at one time threatened the total extirpation of that most useful vegetable; but a gentleman who deserves great credit for the ingenuity and simplicity of his device, has found out that by quartering a few hencoops on the Asparagus-beds and then letting the chickens run about at will they eagerly devour the insect and speedily clear the beds. I have not yet seen the least indication on the Apple trees of what we used to term "American blight," and Long Island has long been famous for its orchards of Newtown Pippins, of which there are abundant existing evidences, many of the trees being of a great age and yet in a good bearing condition. —DAVID FOULIS, *New York, August 17.*

[Mr. Foulis is now in partnership with Mr. Beattie, a nephew of Mr. Forbes, of Woburn, the firm being Beattie and Foulis, Seedsmen and Florists, 925, Broadway.—EDS. J. of H.]

BARR HALL,

THE SEAT OF SIR FRANCIS SCOTT.

A BARONIAL mansion situated on an elevated spot bears a commanding aspect, and may be seen afar off, but viewed from a distance the exposed appearance gives not the most pleasant ideas of comfort within. This cannot be said of Barr Hall and park, in Staffordshire, about six or seven miles from Birmingham, belonging to Sir Francis Scott. The Hall, neither elevated nor commanding, is scarcely seen until you are within a few hundred yards of it, yet when approached it appears to be all that a gentleman's country seat should be. It is certainly a beautiful building of square form, with a neat chapel on one side of it, the offices, &c., being at the rear. The grounds and park surrounding it are the most beautiful I ever saw, due both to the nature of the place, which is hilly and wooded, and the way in which it has been improved by art.

At the back of the house you ascend by winding paths into a thickly wooded region, beyond which you look over the country, which is in a high state of cultivation, being varied with corn fields and meadows, with here and there a wooded spot. From the front of the building the ground is beautifully undulating, and rather thickly wooded, and almost facing it, about a mile distant, is a church half hidden by the trees.

The approach to the house after passing the lodge is by a carriage drive of more than half a mile in length, apparently cut through a thick coppice, with a dense undergrowth of Brakes and Brambles. After a long drive you come to an ornamental piece of water of several hundred yards in length. This is crossed first by a rustic bridge of wood for foot passengers, and further on by a more massive bridge for vehicles. Following the carriage drive past the house, you arrive at the kitchen garden, which is walled-in, and another enclosed space containing the gardeners' residences, also the green-houses, vineries, &c., and beyond these is the orchard, and beyond that again the farms. But I did not inspect any of these very closely.

The pleasure grounds, properly so called, are situated in the space between the house and the ornamental water. From the front of the house a broad walk descends to the water's edge, across which on the opposite side is a boat-house, which you can see into, and at right angles with the house is another broad path and terrace lawn. Below these is another terrace, and below that again is another lawn reaching some distance on either side of the mansion. This is ornamented with beds of flowers in the modern style of bedding-out. The bedding-out here has been done with a view to the best effect. Looking at it from either side it is one of the most pleasing arrangements I have seen this season, there being sufficient space to take off that crowded and elaborate appearance often observable in the bedding system.

Thinking that a description of the bedding-out might prove interesting to some of your readers, I took down the arrangement, and give it as clearly as I can. On each side

of the broad walk leading down to the water is a bed in the form of the clover leaf. These were planted alike, the centre being a mass of *Cineraria maritima*, with Purple King Verbena round it, then Lord Raglan Verbena, with a broad edging of Variegated Alyssum or Königa variegata. Lower down is another pair of large circular beds, these were planted with a centre and four arms, reaching to the edges, of Alma variegated Geranium. The angles formed by these arms were filled first with Lord Raglan Verbena, next Purple King, and the hollow cones thus formed were filled with Variegated Mint kept very dwarf. Next, to the left, were four cones, with the hooked points meeting at the centre, which is a small circular bed of *Ageratum* and *Cerastium*. The first of these beds consisted of *Calceolaria Aurea floribunda*, with an edging composed of alternate plants of *Lobelia speciosa*, and *Königa variegata*, with which the whole four were edged, only No. 2 was planted with Lord Raglan Verbena; No. 3 with *Calceolaria amplexicaulis*; and No. 4 with *Defiance Verbena*; each cone being about 12 feet by 6. A little away from these was a group of eight triangular and two small circular beds. These were arranged in the form of two squares, there being four triangles and a small circular bed in the middle of each square. They were balanced evenly, two beds being of Mangles' Variegated Geranium, edged with blue *Lobelia*; two of Brilliant Geranium, with a like edging; two of Tom Thumb; and two of Trentham Rose Geranium, all edged with Variegated Mint. The two circles were *Ageratum mexicanum* and Variegated Alyssum. From these you pass to a square group of four acutely-pointed, triangular beds, like the others centered with a small circular bed, this being filled with a kind of single-flowered *Tropæolum* of a deep orange colour, edged with *Cerastium tomentosum*. The triangles were masses of Lord Raglan and General Simpson Verbena filling two beds. The other two were *Calceolaria amplexicaulis*. This kind retains a freshness which other *Calceolarias* seem to lose at times.

Passing on a little further you come to a large star planted in the centre with Flower of the Day and Alma Geranium. The eight radii are planted thus—the opposite ones being balanced—viz., two with Brilliant Variegated Geranium, two with Tom Thumb, two with Trentham Rose, and two with Christine Geranium.

Still further on were a series of scroll beds, all planted alike—that is, along the centre of each bed were alternate plants of *Calceolaria amplexicaulis*, *Ageratum*, and *Perilla*, and on each side of these a row of Tom Thumb Geranium bounded by a broad edging of blue *Lobelia*, and Variegated Alyssum, planted alternately, which style of mixing the plants has been freely adopted here, and as regards the effect produced with success, and certainly the scroll pattern and the arrangement of the colours elicited many remarks of approbation.

About this scroll pattern were scattered several small circular beds, filled with Geraniums of various colours, and all edged with *Cerastium*. Beyond these were a clump of *Rhododendrons*; and some shrubs and trees of dwarf habit, which terminated the flower garden in that direction, excepting that over the water were some vases filled with Scarlet Geraniums, fixed as it were on an unfinished bridge.

Going back to the broad walk leading down to the water, and passing from the beds that matched those already described, we come to a series of beds formed similar to the pine pattern of ladies' shawls. These are four in number, and raised above the level of the grass about 2 feet. The first is *Gazania splendens*, in opposition to one of *Calceolaria Aurea floribunda*, and one of a deep yellow *Tropæolum*, opposed to one of *Calceolaria Prince of Orange*. These four beds are centered with a circle filled with *Ageratum*, edged with Variegated Mint. To the left is a raised circular bed of Brilliant Geranium, edged with three rows of *Cerastium*, and to the right a cross, in the centre of which is a mass of Sultan *Calceolaria*, the four parts being Pink Nosegay Geranium, Purple King Verbena, and Golden Chain Geranium. A little way from this is a long border about 5 feet wide, planted in patches consisting of Golden Chain, Flower of the Day, and Alma Geraniums, alternating with Blue Bonnet and Lord Raglan Verbena, Variegated Alyssum, and *Lobelia speciosa*; the whole making up a display which if not grand excited a feeling of gratification, and left

little to be wished for. It will be seen that the materials were few, and the colours far from being numerous; but I doubt if the effect would have been so good had a greater variety of subjects been used in the planting.

On each side of the upper terrace is a row of vases filled with Scarlet Geraniums, which, as any one may be sure, make a great improvement. Looking at this garden across the water, with the mansion, the adjoining chapel, and the rising ground on each side of it surmounted by thick woods for a background, it presented about as good a scene as could well be desired, and certainly the best that could be formed of the place. On the right is a pinetum, beyond this a park, and where the absence of trees allows the view to extend some distance, is a village spire peeping through the trees, and cattle browsing on the hills to the left.—F. CHITTY.

EDINBURGH HORTICULTURAL SOCIETY.

THE autumn Exhibition of flowers and fruit in connection with this Society was held on September 10th in the Music Hall, George Street. Taken as a whole, it was the most successful autumn meeting which has ever taken place under the auspices of the Edinburgh Horticultural Society; while there can be no doubt whatever as to its great superiority in fruit over any exhibition which has ever taken place in Edinburgh before. The quantity of fruit was far greater than the most sanguine could have expected; and the quality of the greater part of it, more particularly the Grapes, was very superior—so much so, that many who had seen the London shows were agreed that the Grapes brought forward on this occasion were in all respects better than those which have appeared at the shows of the southern capital.

While every dish of Grapes was excellent, the first-prize Muscats from Mr. Denholm, gardener to the Duke of Roxburgh, were wonderful examples of good culture. The size of both bunch and berry was enormous, and they were ripened and coloured to the very highest pitch of amber colour slightly mottled with russet spots—a degree of perfection most difficult to work up to. Those from Mr. McDonald, Cupar, Fife, which took the second prize, though not so large as the former and others in the Hall, were also beautifully ripened. Not less remarkable as examples of skilful Grape-growing were the Black Hamburgs with which Mr. Fowler, gardener to the Earl of Stair, Castle Kennedy, took the first prize. One of the bunches weighed 5 lbs. Mr. McDonald was second in this Class also with smaller but very well-finished bunches. For the best bunches of two sorts Mr. Fowler was deservedly placed first with a bunch of Snow's Muscat Hamburg weighing 3 lbs. 10 ozs., and a bunch of Trebbiano 4 lbs. 12 ozs. Mr. Laing, Pitcarlie, Fife, made an excellent second in this class.

A most interesting collection of Grapes were sent for exhibition by Mr. Fowler, Castle Kennedy, consisting of magnificent bunches of Snow's Muscat Hamburg, one bunch of which was nearly 4 lbs., beautifully coloured, and large and equal in berry; Barbarossa, 5 lbs. 13 ozs.; Golden Hamburg, 3 lbs. 9 ozs.; Muscat, 4 lbs. 2 ozs.; White Nice, 4 lbs. 12 ozs.; and one or two more varieties equally fine. One variety, named Black Gibraltar, excited a deal of interest on account of the compactness of the bunch and the immense oval-shaped berries of a brownish-black colour. Mr. Fowler stated that this is a most valuable sort for long-keeping, and that it acquires a very fine flavour throughout the winter months. Even at the present time the flavour is very good, with a firm crackling flesh. There can be no doubt at all that this is a Grape well worthy of more extensive cultivation. The bunch exhibited weighed 3 lbs. 12 ozs. While these are referred to as the most striking examples of good management, there was scarcely an indifferent bunch of Grapes placed upon the tables, and the Judges had considerable difficulty in arriving at some of their decisions. There is one point in which the Edinburgh exhibitors are sadly deficient as compared with those of London, and that is in the matter of conveying their Grapes to the shows, and in many instances the bloom of the Grapes is almost entirely rubbed off in the carriage.

The prize offered by the proprietors of this Journal for the best collection of fruit was contested for with great

vigour, and while all the collections were a credit to any grower the prize ones were most superb; and this is but another instance of the amount of energy that liberal prizes call into play. Mr. Thomson, Dalkeith Park Gardens, was placed first with a most superb collection, consisting of an Enville Pine, Regent's Park Melon, and another named Dalkeith Nerted Hybrid; Lady Downes' Grape, large, and as black as sloes; Muscats; Violette Hâtive and Bellegarde Peaches; Violette Hâtive Nectarines; Musa Cavendishii; Doyenné Boussoch, Beurré d'Arnhemberg, Reine des Poirés, and Jargonelle Pears, all except the latter being from trees in pots and very fine; Moorpark Apricots; Goliath, Jefferson, and Magnum Bonum Plums; Apples, Cherries, Currants, and Gooseberries. Mr. Melville, Dalmeny Park, was second with Black and White Grapes, Pears, Apricots, four sorts of Plums, Peaches, Nectarines, Cherries, Figs, Melons, &c. This was also a very handsome collection of fruit. The third prize was awarded to Mr. Gordon, Niddry. Besides these there were other five competitors for this prize, and their collections were all very good.

Pine Apples were not numerous but well represented, particularly by Mr. Foulis, Fordel Gardens, who took the highest honours with an excellent Queen and Ripley Queen.

Melons were plentiful and good; Mr. Weir, of Kerse House, and Mr. Denholm, Broxmouth, being the successful competitors in the order in which they are named.

Peaches, Nectarines, Pears, Plums, Apples, &c., were in great abundance, and in more than usual fine condition.

In the cut flower department Hollyhock-spikes presented a very imposing array; and Dahlias, Verbenas, Asters, Marigolds, and Gladioli were exceedingly plentiful. Pot plants were the weakest point of the Exhibition, and there was nothing amongst them calling for special notice. Tables of plants were brought forward by the various nurserymen of Edinburgh, and several very tastefully-filled baskets of plants such as are suitable for sitting-room decoration.

GROWING PARSLEY FOR THE WINTER.

THE preservation of Parsley in a fresh and green state during the winter season is frequently attended with much difficulty where the convenience of frames is not available for this purpose. In the more northerly counties, indeed, Parsley is only to be procured at much expense during nearly six months out of the twelve. The leaves of this useful vegetable when grown in the open ground are generally destroyed by frost; but if the circumstances attending their destruction are fully considered, it will be found that the stems are most rapidly affected where the soil is stiff and moist, and where the situation is exposed to cold cutting winds. The plant, however, does not appear to be so delicately constituted but that it may be had with comparative ease all the year if the ordinary conditions of growing the less hardy plants during the winter are observed. Some varieties are, perhaps, more susceptible to cold than others.

The finest sample I ever saw was grown on the west coast of Scotland by a village schoolmaster. It was of a beautiful green colour, and of a remarkably vigorous habit; but growing in a low situation and exposed to cutting sea gales, the leaves always died down during winter.

In ordinary situations Parsley may be grown successfully on a border having a south aspect and protected from the north by a wall. The soil should be light and rich. A quantity of stones and brick rubbish should be laid at the bottom to the depth of 7 or 8 inches, so that the bed may be raised considerably above the general level of the ground, and thus insured against excessive moisture. The surface of the soil being properly raked, seed of the most curled variety that can be obtained should be sown very thinly, either in shallow drills or broadcast, and slightly covered with fine soil. This operation should be begun in May or early in June, and if the weather continue dry, frequent waterings will be necessary. The young plants will have sprung up in six or seven weeks, and when large enough they must be thinned-out to 4 or 5 inches apart. They will have become large and vigorous by the end of autumn, when a number of stakes should be driven into the ground along each side of the bed. These stakes should be of a thickness to permit of their being bent across and tied together so as to form a series of arches, and strong enough to support a covering of mats, which should be laid over them as soon as the weather becomes frosty and wet. During intense frost, especially at night, it may be necessary to increase this protection by doubling the mats; but these should be removed entirely while the weather is mild. The soil should be kept as dry as may be, and all decaying matter carefully removed from the plants. A bed $4\frac{1}{2}$ feet wide by 10 long will contain as many plants as may be sufficient for an ordinary supply during the winter.

Parsley might also be grown on a sort of rockwork with great certainty and convenience, for on such a structure the roots and stems could be kept in that dry state which is so indispensable to their health and freshness in dull cold weather. For growing it in this way, it is recommended to sow a quantity of seed early in May in a bed of light rich soil on a south border. When the young plants are a little above the ground they should be thinned-out to 6 or 8 inches apart, kept clear of weeds and watered as occasion requires. At the end of August, or early in September, collect a few barrowloads of moderately large stones, selecting such as are best suited for forming a rockwork. They should be longer than broad, somewhat flat or even at the sides, so that they may lie firmly in their places when built up. Any kind of stones which the district may afford will do; but those of a sandy or porous composition should be preferred when a choice is offered. Bricks may also be used, but they are, perhaps, too flat, and do not present those holes and crevices which are desirable in the formation of rockwork, and which may generally be secured by the use of stones. The site being chosen in some sheltered open part of the garden, the stones and a quantity of good friable sandy loam, with some brick rubbish or rubble, should be collected together. The rockwork must be determined according to taste and requirements, in respect to form and size, but there is no use in having it too large. Perhaps the oval form is the most convenient for building such a structure, and if the base is 5 feet long, a pile may be raised with a surface extensive enough to grow a sufficient supply for an ordinary family. The stones used in forming the first tier or layer may be about 8 inches high and kept close together. A quantity of soil should be worked-in at the back and sides so as to keep them together, while the centre may be filled with ordinary brick or sandstone rubbish. When the first layer is completed a portion of the soil should be laid over the stones at the side, and a number of plants of Parsley, taken carefully up from the bed in which they have been growing, should be planted as regularly as possible in all the holes and crevices, their roots being spread out in the soil, and their stems and leaves kept inclined outwards at the margin. Having fixed the plants properly, proceed to erect a second tier in the same way, and so on with the others, till the pile is raised to the height desired; but with the subsequent tiers keep the stones $\frac{1}{2}$ or 5 inches nearer the centre all round, and about an inch or so apart. Every stone should be placed directly

over the point which forms the junction of those immediately below it; and every additional tier which is raised must be kept 3 or 4 inches nearer the centre than the one preceding it, so that when the whole structure is completed an imaginary section of it would appear thus. In this

arrangement of the several tiers the plants will not come directly over another, and the soil will not be washed down from the interstices by rain. If at the time of building the rockwork the weather is dry, the soil about the plants must be well soaked with water; but this must be done by limited supplies repeated several times, for if much water is poured on at once, a portion of the soil will run down. To prevent the action of drenching rains from having the same effect, it will be necessary to provide the winter covering at once. A number of stout ash sticks must be driven into the ground about 12 inches from the bottom of the rockwork, and attached by a good strong cord, so near one another that they may form an open arching figure at the top, and so placed that at any point they may be 12 or 18 inches clear of the plants. A covering of oilcloth or common canvas should be provided and kept in readiness to protect the mound from heavy falls of rain until the soil has become consolidated round the sides. This covering will also be available during intense frost, when it must be carefully laid over the whole frame of sticks and removed whenever the weather is mild and open. In eight or nine weeks the pile will have become covered with strong healthy plants, which, besides affording a continual supply, will form an agreeable object both in summer and winter. It may be urged that by this plan of growing Parsley the roots are liable to become dry in summer; but in admitting the probability of such a circumstance, we must bear in mind that if the plants could be kept from growing too vigorously during the summer months, they would be in the best condition for preservation during frost. Now the drought of a hot summer would have the effect of retarding them, and conserving their energy until the time when their growth was most desirable. Besides, any extreme dryness could be very easily prevented by timely applications of water.

A Dutch method of growing Parsley during winter is to sow the seed in March, so that the plants may be vigorous enough for removal by the end of September, when they are planted in large pots, somewhat similar in form to what is used in England for blanching Sea-kale, or, perhaps, rather like the annexed figure. The vase is open

at the top and perforated with large holes all round. In September it is filled with soil, and the plants are inserted in it at the holes, their stems and leaves being kept out-

wards. This vase may be made to any size, and as ornamental as taste may determine.—(P. F. KEIR, *Gardeners' Magazine of Botany*.)

KEELE HALL.

THIS delightful residence of Ralph Sneyd, Esq., is beautifully situated on the brow of a hill, three miles from Stoke and five miles from Trentham. The whole neighbourhood might be searched before finding a more suitable position or one commanding richer and more varied views of the surrounding landscape. And yet, notwithstanding its elevation, so well is it sheltered and backed by timber, that though so near to Stoke and its potteries, and within two miles of Silverton and its mines, but for an occasional streaky cloud in the clear atmosphere, interesting and pleasing rather than otherwise (though giving some little idea of huge chimneys which you cannot see), you might imagine yourself to be ruralising amid the wild grandeur of a rich Arcadia. Of what may be denominated the principal approaches I cannot speak, as I had the privilege of going from Trentham; and after passing a rustic gate could not help admiring what some years hence will be a splendid avenue of Spanish Chestnuts, the ground rising all the way to the stables with a noble archway for an entrance, and passing through the square on to the mansion through a deep cut in the red sandstone, of a superior sort of which sandstone the fine stables and the still superior mansion are chiefly constructed.

There is always a little difficulty in settling on the best mode of describing a place, so as to make it interesting to the reader; but as the fame of Keele Hall consists chiefly in its horticultural productions so far as gardeners are concerned, and as Mr. Hill's compact and very commodious house abuts on the west side of the stables, the gardens of utility being immediately in front of it, and as to these our attention was first directed, we will just take our readers along the pathways we traversed. We may observe that the front of the house showed the presiding genius of Mrs. Hill in a few beautiful flower-beds, in one or two of which, as in a post of honour, was planted a pretty seedling *Verbena* of a rich crimson magenta-colour, which, we think, from its dense habit deserves to be better known; and this again was flanked on a higher level by masses of *Picotees*, *Carnations*, and *Cloves*, some white seedlings of the latter being very fine. However enthusiastic a gardener may be, it is a sad drawback to him if there is no sympathy as to his favourite pursuits between him and his partner at home. You may always reckon surely on that sympathy where you see good plants or boxes in the windows and elegant flower-beds near the doorway. From what little I saw of the midland counties, owing to the incessant rains, I could only come to the conclusion that the gardeners in that district are highly favoured in this respect, and to it no doubt owe no little part of their great success.

The soil of the kitchen gardens, lower and upper, is composed of a rich stiffish red loam resting on the red sandstone. From the slope of the gardens we could scarcely suppose it possible to suffer from wet in a moist dripping season; whilst the depth of the soil and the cool sandstone beneath prevented anything suffering from such dry seasons as the present, as was amply evidenced in the heavy crops of Onions, Carrots, Cauliflower, and some of the finest late Peas I ever witnessed in the end of August. This lower garden is surrounded by a wall 12 feet in height. On the south aspect is a Peach-wall looking well; but Mr. Hill complained that unless in fine seasons they did not ripen kindly. There were iron rods from the top of the wall to 3 feet or so on the border, and they stand through the season for supporting the canvas used for protection; but Mr. Hill well said that a covering of glass for a quarter of the space would secure on an average more good fruit for the table. The south-west wall is occupied by Pear trees in a state of great fertility and luxuriance, and by grafting several sorts on some trees a good supply is afforded from August to April, beginning with *Citron des Carmes* and *Jargonelle*, and ending with *Easter Beurré* and *Beurré Rance*. In May, 1858, Mr. Hill had a certificate from the London Horticultural Society for fine fruit of the latter. In general the

Pears on this wall are of large size, the *Beurré Rance* being frequently fully 1 lb. in weight. On the opposite side of the walk that bounds the borders of these fruit-walls is a narrow circular trellis (see fig. 1), chiefly devoted to Apple trees in good condition, and which trellis looks very neat. It is $2\frac{1}{2}$ feet wide at the base, and 5 feet in height to the blunt circular apex. The crops were deficient this season, owing to the severe frost on the 20th and 21st of May.

Fig. 1.

But passing these, general cropping, lots of hotbeds, and Asparagus-pits where the plants grow where they are to be forced, we come to the ranges of hothouses which have made Keele Hall garden and its superintendent so illustrious; Mr. Hill, in the course of nine or ten years, having taken about sixty first prizes for fruit at the metropolitan exhibitions. The very best of the fruit had been cut from the earlier houses; but sufficient remained in later ones and others ripening to show very superior management, and also to prove conclusively that the success was no haphazard affair—no happy result occurring from merely sticking a Vine into the ground and letting it take its chance of succeeding or failing, but the consequence of much thought and study as to the best modes of management and a constant unwearied attention to the smallest minutiae of practical details. Owing also to the combined liberality and the mechanical and artistic taste of the worthy proprietor, all the structures about the garden were in first-rate condition, and furnished with the best modern improvements as to ventilation, &c.

The first range of houses we entered consists of four vineries, each 31 feet long, 16 feet wide, $10\frac{1}{2}$ feet in height at back, and 3 feet in height at front. These heights refer to that above the surface level. The front 3 feet above the wall-plate is of glass sashes, opening outwards all at once by a rod, &c. The border inside is nearly up to the glass A (see fig. 2, made merely from memory). B is the back

Fig. 2.

path 4 feet wide, bounded by a neat curb, from which a pillar C goes to the roof at every $4\frac{1}{2}$ feet. On these pillars in some instances Vines are also trained, and an arch goes from pillar to pillar. The two middle vineries are for the earliest Grapes; and the borders for these at least, if not for the whole of the range, are chambered or arched underneath. The outside borders E are 9 feet wide, and are arched underneath at F, communicating with linings G, covered with board flaps, so that dung may be placed under the arches and the heat kept in. H is the pathway in the front, and the ground gently falls from the pathway.

Now let us glance at some of the peculiarities of these first-rate vineries. First, from the elevation of the borders, the chambering, and means used for drainage, it is utterly impossible that the Vines can suffer from stagnant moisture, and therefore nourishment can be freely given to them. Secondly, the Vines are all planted inside, about 18 inches from the front glass, and in every case the inside border is higher than the outside one, but with free communication between them. Thirdly, all the heating-pipes are 4 inches in diameter, and are placed pretty regularly and level across the floor of the house—a plan which we consider far prefer-

able to placing pipes in tiers above pipes, as we have them, because we found them so. These pipes in all the houses at work were well coated with sulphur. There was an exception to this placing the pipes on the level, and we consider a valuable one, in the shape of two small two-inch pipes, placed over each other some 18 inches from the base of the back wall. These, so placed behind the pathway, prevented any stagnation of air there, made the circulation of the internal atmosphere more complete, and alike enabled and required top ventilation to be more freely given. Then, fourthly, instead of sinking a huge pit for a Vine-border, it will be perceived that the whole, inside and out, is above the ground level; and then, again, there is the opportunity of heating these borders from beneath. The arches are formed of brick and good mortar, so that little or none of the enriching gases from the dung can reach the roots, nor is it desired they should do so. A root now and then may find its way through the mortar into the chamber, but it is soon destroyed by the heat or removed, as Mr. Hill has no idea of having a forest of spongy roots whitening the top of his arches: he wishes these all to be confined to the good material above which he gives them so liberally. This mode of heating the borders from beneath with dung involves a great amount of labour and constant supervision, as the heating material is subject from mere changes of weather to great and sudden fluctuations of temperature.

On this account it is proposed to dispense with the dung and use hot water as being much more under command. With this heating from beneath, a slight covering—say from 9 inches to a foot—of dry leaves or litter is sufficient to keep up the desirable temperature in the borders, more especially as that covering is kept dry by moveable wooden covers 4 feet wide, and in length so that one or two lengths go over the border. These covers are made of rough boards fastened to cross pieces, and then a slip 2 inches wide tacked along each joint—a capital plan where green unseasoned wood is used, and even for any wood exposed to great alternations of wet and dryness. These well tarred will last a great many years, and will come in for many purposes of protection in the spring and autumn. Mr. Hill uses them largely in temporary pits, for protecting his bedding plants in spring. And, lastly, the borders were made simply of the very best materials. Some new ones that we examined seemed to consist chiefly of about half-inch slices of the fibry top part of some old pasture with a very liberal allowance of boiled bones. I would rather that such men as Mr. Hill and Mr. Henderson would tell us the quantity in proportion to soil rather than make a rough guess at it. These bones are boiled at the potteries for obtaining the gelatine, &c., and after this boiling the fermenting and rank properties are so greatly removed that they may be used to a much greater extent than fresher bones could be with propriety.

Though equally well chambered or drained the two end houses were for late Grapes, and would require no heating from beneath whilst so used. One of these had been planted in November, chiefly with Lady Downes' and Alicante, Kempsey and Meredith's, as far as we recollect, and they were now strong canes rising to and along the back of the house. In this house Vines were also trained to the rods by the sides of the path, where, no doubt, they would remain until the finest ones monopolised all the space. The laterals near the top were merely stumped in; but they had been removed fully half way up the stems, and would be removed gradually all the way to expedite the hardening and ripening of the wood. Some fine Azaleas stood in open spaces between the pillars. In the other end vinery, among other good fruit, were some huge bunches of the Trebbiano Grape approaching maturity.

From one of the middle vineries the glass was removed and the Vines closely pruned-in preparatory to cleaning them and the house thoroughly. In the other, though the fruit was all gone, the wood was in fine condition. Here I noticed that a number of small shoots near the base of the Vine had been grafted with new or more desirable kinds, and after the graft had taken the shoot was laid or taken through a box filled with good rich material, and, rooting in the

box, derived extra strength before the roots of the grafted part established themselves in the border beneath the box.

The second range in the same garden consists of two vineries and one early Peach-house, each 52 feet long, 17 feet wide, 15 feet high at the back, and 14 feet in front, air being given there by a moveable louver-board. One vinery had been cleared, but contained fine short-jointed wood. The second had some excellent Lady Downes' and Hamburgh Grapes; and the Peach-house was cleared, but the wood in excellent bearing condition. The rafters, I think, were about 4½ feet apart, and there was a Vine up the rafter and also one in the centre between. Here the same attention had been paid to drainage without chambering. The Peach trees were trained under the roof on two trellises, from two sets of trees, dwarfs in front and standards behind, against the columns, which Mr. Hill considers much preferable to having standards against the back wall, to be so far shaded by a trellis in front. In *fig. 3* 1 is the lower trellis, and 2 the upper trellis.

Fig. 3.

In the upper kitchen garden is a splendid range of glass, with a lofty conservatory in the centre. Taking them as they come, we first notice a Peach-wall fronted with glass, on which were many fine fruit, and the trees are almost sure to produce a heavy crop with far less care than on the open wall. This house is 116 feet long, 12 feet high at back, scarcely 1 foot in front, with louver-boards made to open upwards, and the sloping part of the roof is also made to open upwards: the width at base is 4½ feet. The front is very neatly supported on iron bars, which gives it a very light elegant appearance. Our recollection of this house is something as shown in *fig. 4*. The sloping shut roof at *a* is glazed. The trees looked remarkably well.

In front on the border were four masses at equal distances of the *Tritoma uvaria*, which were very magnificent, averaging from four to five dozen heads of flowers to each. We forget now how long they had been planted, but Mr. Hill kindly told us what he considered the two points essential to their successful culture. The first was, to dig out a good hole for them, and to fill it with good turfy loam

Fig. 4.

and rotten manure, and the second was, never to remove a leaf, be it broken, be it green, or withered and several years old. On examining their bottoms we found masses of old withered leaves, but concealed by the green ones, and these formed the best of all protection for the plants.

We next came to a very fine Muscat-house 52 feet long, 20 feet wide, 10½ feet high at back, and 5 feet high in front; length of rafter 21 feet, width of path about 4 feet; but a small border is placed close to the back wall, against which were growing Shadlocks, Lemons, &c. The Vines here are all planted inside, and are about thirteen years old. The whole crop was good, but some bunches at the east end were very fine. The house is roofed, small ridge-and-furrow fashion, the ridges being 2½ feet at the base, and 1½ foot at sides. The Vines are trained up the furrows of the ridges, and are, therefore, 2½ feet apart. The borders inside and outside are made as respects their bottom also in the ridge-and-furrow style, which renders the drainage more perfect. The front of the outside border as at *c*, *fig. 5*, is supported by a low wall, screened by a similar close hedge of Yew, and through these there are drain-pipes communicating with the surface of the walk *b*, besides the other drainage at the bottom. In the case of this fine house, too, the most of the border is above the surrounding level. In ventilating in front, the large upright sashes open outwards by means of a lever, and the back ventilation is effected in a very superior way by double louver-boards of iron, communicating with a hollow chamber in the top of the wall, which has a connection above the glass with the external atmosphere. The advantage of this plan is, that in the coldest weather the fresh air at top will be ameliorated and softened, and warmed before it passes in among the tender fruit and foliage. The house had previously been used as a pit for Pines and plants requiring stove heat, and a portion of these pipes had been sunk for bottom heat. On removing the pits to give the Vines the benefit of the whole house, these pipes were raised, and now there are seven four-inch pipes all on a level placed along the floor of the house. Mr. Hill is a great advocate for plenty of piping, and never over-heating the pipes, contending, as we have often done, that the extra heating of a small amount of piping is only a waste in whatever way it is looked at. A small amount of piping is often, as respects fuel, the exemplification of the old adage, "Penny wise and pound foolish." Mr. Hill assured us that even in very cold weather, and when the house was kept to 70°, these pipes were never so hot but that a person might sit down on them comfortably. On clearing out the pits the inside borders were not all made at once, fully half the space yet remains to be filled up, and thus the Vines can have a little more feeding-ground for a number of years to come. We here noticed several nice bunches of Foster's White Seedling, very interesting not only on its own account, but also from being said to have come from the same berry as that which produced the celebrated black Lady Downes' Grape.

The conservatory being in the centre, there is at the opposite end a Black Hamburgh-house of the same dimensions as the Muscat-house, whilst the outside and inside arrangements are similar. Here, too, the inside border is as yet only partially filled. Mr. Hill imagining that these Vines planted twelve years ago were deteriorating a little, lifted the roots last November, replanted them carefully in fresh

Fig. 5.

fibry loam, with some rotten dung, and broken boiled bones, covered the soil with about a foot of tree leaves, above which the wooden covers spoken of were placed, and did not at all hurry the Vines, and now there are about 250 bunches of what promise to be excellent Grapes. A Fig-case of 40 feet,

and in the same style as the Peach-case, terminates the range in this direction.—R. FISH.

(To be continued.)

COLEUS VERSCHAFFELTI AS A BEDDING PLANT.

IN reference to the communications in the August Numbers of THE JOURNAL OF HORTICULTURE, by Mr. Adey and "D.," of Deal, pages 103 and 146, respecting the *Coleus Verschaffelti*, wherein Mr. Adey states, "It is sentenced to perpetual imprisonment in the greenhouse;" and "D.," of Deal, that "it is a complete failure," I beg to make the following observations:—

In the first week of June I planted a small bed, sheltered from the north and east winds, with the *Coleus Verschaffelti*, the plants being only about 6 inches in height, having been struck late in the spring. They were planted 10 inches apart. In the first part of the season they made very slow progress, but since then they have grown remarkably well, filled up the bed, and are now sufficiently large to enable me to take between twenty and thirty cuttings from each plant. The colour is very rich, much more so than that of the *Amaranthus melancholicus ruber*, and particularly so when the sun is shining upon the bed.

My motive for writing these few remarks is, to suggest that before we discard, as a bedding plant, the *Coleus Verschaffelti*, which is so beautiful in foliage and easy of culture, I hope our friends will give it a further trial, and that we may hear the results of such trials in the pages of THE JOURNAL OF HORTICULTURE.—WM. POTTEN, *Gardener to Mr. Wilson, Camden Lodge, Sissinghurst.*

I CAN fully bear out what Mr. Earley says respecting this plant for bedding.

I had one plant last spring, and having made a small flower garden where we wanted all the variety we could obtain, I thought I would try it. I took off every cutting as soon as the young plants made three or four eyes, till the first week in April. They were grown as fast as we could without their being drawn till the first week in May. They were then put in a cooler pit for a week, and afterwards removed to a cool Peach-house till the 9th of June, when they were planted out. They were covered for about a week with mats at night, and they have been admired the season through by all who have seen them, and they are looking well now.—J. GOUGH, *Lea Castle Gardens, Kidderminster.*

FLOWER-BEDS ON A TRIANGULAR PIECE OF LAWN.

IN the garden at the back of our house we have a triangular piece of grass. There are three beds of evergreens, one at each corner, and on the grass are four round beds, each 10 feet 4 inches in diameter, and we find a great difficulty in endeavouring to fill these with flowers of heights and colours corresponding. This year we had two filled with a scarlet *Verbena*, and dotted with the Oak-leaved *Geranium*, and the other two were filled with *Gazania splendens*, dotted with *Cineraria maritima*, but they were not satisfactory, and we are anxious to fix how they are to be filled next summer, in order that our gardener may know what to propagate now.

A bed near those I speak of was filled with *Lobelia speciosa*, dotted with *Cloth of Gold Geranium*, and three other and larger beds on another piece of grass were filled, one with *Phlox Drummondii*, one with *Calceolaria Aurea floribunda*, and the other with *Tropæolum elegans*.—AN OLD SUBSCRIBER.

[From your description of the plot of ground with the evergreens at the corners, we presume that the four beds for flowers consist of three beds alternating with the evergreens, and the fourth a centre one. If this should be the case, the three ought to resemble each other in the height and habit of the plants grown, but the centre one may be different. And in many similar cases we would have said, Make the three outside beds *Verbenas* of different colours, but alike in

growth, and the fourth *Geranium*; but as you say *Verbenas* have not been satisfactory, something else might be tried. In a general way, dotted or mixed beds look best in isolated positions, and but rarely look well as forming features in a series of beds; and as your beds are small, we would plant the centre all with one kind, and edge it with another. If your beds would allow of a small dot in the centre, you might make three very effective beds, by planting a small centre piece—say 18 inches in diameter, with *Alyssum variegatum*, then a ring of something more than a foot wide with *Lobelia speciosa*, and an outer edging of *Cerastium tomentosum*. These three beds would by this means be all blue and white, the latter being foliage will be more durable than any flower; but the *Lobelia* is, perhaps, the most lasting of any flowering plant our gardens possess. Now, supposing these three beds form the outer series, and, as above advised, to be all blue and white alike, we must have something else for the centre—say *Tom Thumb Geranium*, with an edging of *Mangles*, or it may be *Golden Chain*. If this bed be only 5 feet in diameter, there is only room for one kind of plant for the centre and main portion of the bed, and one for the edge. As foliage is always of longer duration than flowers, the appearance of *Golden Chain* and *Cerastium* as edgings to beds will always be good from the time of planting up to the latest period in the season. If your beds had been larger, more variety might have been obtained, but in small beds only low-growing plants. In a general way, ought to be grown; and as you possess other beds where *Tropæolums*, *Calceolarias*, and other things may be grown, the mere fact of limiting those beds in question to so small a collection of plants need not be found fault with. The prettiest designs in flower-gardening contain but few colours, and a repetition of the same form is met with in all objects of art. If your garden possessed only the four beds alluded to, we might have advised more variety; but as it is, we should in our own case be content, for one season at least, with planting the beds in the manner advised.]

PRONUNCIATION OF GLADIOLUS.

IT is very amusing to read in your No. 127, "that there is no doubt" as to the proper pronunciation of *Gladiolus*, and that it is to be pronounced *Gladilus*. In the first place there is very great uncertainty, until the dictionary has been consulted, as to how it ought to be pronounced; and after that has been done I will engage that there is not a Latin scholar in the kingdom who would pronounce the word as if there were no *o* in it—*Gladius*, a sword; *Gladiolus*, a little sword. So far from omitting the *o*, the modern Italian lays the accent on the *o*, *Gladiola* or *Gladola*, omitting the *i*. So that not only is there great doubt about it, inasmuch as the modern and ancient tongues of Italy differ about the word; but that under no supposition whatever can your dictatorial correspondent be right in his assertion. If he is one of your staff, pray fine him a week's pay.—F. COOK.

[We are exceedingly obliged by the note of "D.," of Deal, which we published in our last Number, and by the above communication, and we assent to most that they advance; and if *Pliny*, *Columella*, *Palladius*, and *Apuleius*, the only ancients who employ the word, we believe, had written in verse, they would have sustained, probably, by its metrical employment, all the short syllables claimed for the word by our friendly critics.

But that is not the question. The question to be answered in our pages is, What is the pronunciation accepted among gardeners? We replied, and we adhere to our reply, *Gladilus*. If we are asked for evidence to sustain our statement, we replace in the witness-box Mr. Beaton, who wrote as follows in our earliest volume:—"It may be as well to put you on your guard against a common provincial way some people have of pronouncing the word *Gladiolus*, by putting the accent, or stress, on the letter *o*; whereas the true way of uttering the same is as if written *Glad-eye-lus*, putting the accent on the *i*."—(*Cottage Gardener*, i., 100.) Mr. Beaton was the right-hand man of Dr. Herbert, and others, who devoted great attention to this genus of bulbs, and, therefore, he knows how they pronounced the word, and, as we have already observed, the pronunciation generally accepted by gardeners is the pronunciation we accept.

The grammatically correct pronunciation of floral names cannot be insisted on; and he would be derided as pedantic who attempted to pronounce *Anemone*, *Fuchsia*, and many others in accordance with their derivation.—Eds. J. or H.]

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

BOWENIA SPECTABILIS (Showy (Australian) *Bowenia*).—*Nat. ord.*, Cycadaceæ. *Lin.*, Dioecia Polyandria. Native of the banks of Endeavour River and Rockingham Bay.—(*Bot. Mag.*, t. 5398.)

CATASETUM CERNUUM (Drooping *Catasetum*).—*Nat. ord.*, Orchideæ. *Lin.*, Gynandria Monandria. Native of Rio Janeiro. Flowers green spotted with purple.—(*Ibid.*, t. 5399.)

SILENE ELIZABETHÆ (Elizabethan Catchfly).—*Nat. ord.*, Caryophyllæ. *Lin.*, Decandria Trigynia. Native of Italy. "A very handsome and rare hardy perennial." Flowers $1\frac{1}{2}$ inch diameter, bright rose colour.—(*Ibid.*, t. 5400.)

HOMOIANTHUS VISCOSUS (Clammy *Homoianthus*).—*Nat. ord.*, Compositæ. *Lin.*, Syngenesia equalis. Native of Chili. Sent by Mr. Pearce, collector for Messrs. Veitch & Son. Most probably hardy, and good for summer bedding. Flowers in June, bright purplish-blue.—(*Ibid.*, t. 5401.)

MUSA SAPIENTUM var. VITTATA (Striped-leaved Common Plantain).—Native of the Island of St. Thomas, in the Bight of Benin. Leaves striped transversely with dark green.—(*Ibid.*, t. 5402.)

INIAS.—Varieties raised by Messrs. Hooper, Covent Garden. *Crateroides*, crimson; *Vittiflora*, green; and *Plantus*, yellow.—(*Floral Magazine*, p. 161.)

RHODODENDRON, *Countess of Devon*, raised by Messrs. Lucombe, Pince, & Co., Exeter. White upper petals spotted with purplish-crimson.—(*Ibid.*, p. 162.)

BOURBON ROSE, *Rev. H. Donbrain*, raised by M. Margottin, Bourg-la-Reine, near Paris. Genuine carmine and very fragrant, form of Louise Odier.—(*Ibid.*, p. 163.)

PYRETHRUMS.—Varieties raised by Mr. Salter, Versailles Nursery, Hammersmith. *Poseum album*, bright rose with white centre; *Lysias*, crimson; and *Princess Alexandra*, pure white.—(*Ibid.*, p. 164.)

HYBRID PERPETUAL ROSE, *Mrs. William Paul*, raised by M. Verdier, Rue du Marché aux Chevaux, Paris. Dark crimson-purple.—(*Florist and Pomologist*, ii., 121.)

PEARS, *De Muraise*, very beautiful and very first-rate. Ripe through November and December. *Belle Julie*, a delicious Pear, ripe at the close of October.—(*Ibid.*, p. 128.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHILE the dry weather continues hoe every part of the garden thoroughly, as those seeds that were ripened in summer (where weeds were allowed to perfect seeds and to shed them), have now vegetated and may be destroyed effectually, which is better than allowing them to stand over till spring amongst other crops. When a kitchen garden is, at this season, well stocked with autumn, winter, and spring crops, all neatly arranged and well cultivated, and the walks, &c., in good order, we think this not at all the least interesting period of the year in this useful department of gardening. As the summer crops are removed manure and dig, or trench the ground, before the autumnal rains set in. In stiff soils this is of the greatest importance. *Cabbages*, plant out immediately the main crop for spring, and after planting take the first opportunity of a dry day to fork all over between the plants. If this is occasionally done there will be no necessity for earthing-up, as the plants if not put too near together will grow short and stocky. *Capsicums*, the green pods of the large sorts should be gathered if there is any indication of frost. *Cauliflowers*, prepare ground in a south border or other favourable aspect for planting Cauliflower plants under hand-lights. A quantity may be pricked out in cold frames to receive protection from severe frost in winter. *Celery*, when attending to it on no account let it be earthed-up so as in any way to bury the heart of the plant. *Endive*, continue to tie it up for blanching. It may also be blanched with slates or tiles

laid on the plants; this saves time, but at present tying is to be preferred. *Lettuce*, prepare ground for plantations of Brown Cos and Hardy Green. A double row of them or any other good hardy sort may be planted at the foot of the south, east, and west walls, the plants to stand 4 inches apart in the row, and if they should stand over the winter, which is sometimes the case with a little protection in severe weather, every alternate one can be removed to form other plantations. *Onions*, transplant the autumn sowing when they are a few inches high on a warm border. Let them be put in rather thickly to allow for pulling out in the spring. Of course, a portion may be left in the seed-bed, but it is preferable to transplant the whole.

FLOWER GARDEN.

Hollyhocks and Dahlias will still require occasional looking after to secure them against the effects of high winds which may now be expected. Herbaceous plants will likewise require the stalks of decayed flowers to be removed, and such as are still in bloom to be carefully tied up. Asters, Phloxes, &c., will now be making a fine show, and should have corresponding care bestowed upon them. Let the borders be cleaned, filling up vacant places with spare Chrysanthemums, spring-struck Pansies, or spring-flowering bulbs. Carnation and Picotee-layers which are sufficiently rooted, to be taken off and planted or potted. If potted, it is not advisable to use soil of too rich a nature to winter them in, and a couple of layers in a 48-sized pot will be sufficient. See that faded blossoms and seeds are removed from flower-beds and borders, other blossoms will be thus encouraged. Much of the vital energy of a plant is expended in the perfecting of its seeds.

FRUIT GARDEN.

Look over fruit remaining out of doors and gather it as it becomes fit, as if it become over-ripe it will be liable to be blown down and bruised; also, examine that in the store-room frequently, as there will occasionally be a few decaying fruit found for a few weeks after housing, and these should be removed as soon as they are perceived. Keep the fruit-room cool and airy in order to allow of the escape of the moisture given off by the fruit, which is considerable for a few weeks at first. Examine Plums or any other fruit protected occasionally by covering to see that they are not spoiling. Where it is intended to make any fresh plantation of fruit trees this season, the ground should be prepared at the earliest convenience, and any fresh soil to be used for planting should be thoroughly exposed to the action of the weather, so as to have it in a mellow state when wanted for use. Filberts are now ripe in most situations and should be gathered. They generally keep in good condition in a moderate-sized hamper. Packed firm, in this way they do not suffer from excess of moisture, and the kernels keep plump and sweet till May or June.

GREENHOUSE AND CONSERVATORY.

The most desirable object in the management of the majority of plants in these structures, and one which must be constantly kept in view, is that of procuring a robust and hardy growth, and of lessening their vital energy that they may gradually accommodate themselves to the changing circumstances of the season. The influence of the autumn weather should be permitted to exert in a degree its legitimate influence. Ventilation judiciously managed will assist in accomplishing the result recommended. Water will be required in less quantity both for the roots and foliage. As all the more delicate greenhouse plants are by this time housed, the few remaining out may be allowed a short time longer out, provided the weather continue dry. Camellias, Chinese Azaleas, and some Acacias will not be hurt for a week or two if circumstances do not permit of their being housed immediately. Give all the air possible to Heaths and other hardwooded plants, and bring Chrysanthemums, Cinerarias, &c., under cover as soon as you can find room for them. Thin-out the bloom-buds of Chrysanthemums, and water with liquid manure. The climbing plants to have frequent regulation, shortening back the shoots going out of bloom, and training the remainder in a suitable manner, to effect a free natural habit.

STOVE.

The twiners on the roof here should also now be more than ever kept within bounds, cutting back all shoots that have

done flowering, and tying the others so as to obstruct light as little as possible. Place specimens ripening their wood in the coolest part of the house, and water sparingly at the root. Achimenes, Gloxinias, and Gesneras that are properly ripened-off may be stored away in any dry place where they will be secure from frost; but take care to place them where they will be free from damp, and they should not be exposed to a lower temperature than 45° or 50°. To effect this a spare house or pit is best for the purpose, when they can be placed near the glass; to be supplied with water only to keep them from flagging. This will allow the foliage to ripen gradually, and, as a matter of course, the tubers. Amaryllis and the different varieties of Japan Lilies require the same treatment; the latter, however, being more hardy, may be ripened-off at the base of a south wall or cold pit.

PITS AND FRAMES.

Mignonette, Stocks, &c., should now be placed in their permanent situation for wintering. The Lily of the Valley intended for forcing should now be potted and plunged overhead. The Neapolitan Violets may also be potted, and plunged in a cold frame in a sunny situation. Continue to pot-off cuttings immediately they have made roots. See to securing as many cuttings as possible of any scarce plants which it may be desirable to increase while there is a fair chance of rooting them, and also be prepared to protect Scarlet Geraniums and other things which it may be intended to take up and winter, for we may expect frost at any time at this season. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

WE hope our friends in the north will have a share of the splendid weather we have lately had, instead of the floods which have visited them almost without intermission. Trenched over our Onion-ground, placing some short manure from lawn-mowings, &c., at the bottom; and planted out with the main crop of Matchless Cabbage. Find already we will have two enemies in this somewhat exposed quarter. The first morning we saw some twenty plants hanging their heads, and found they were cut over beneath the surface by huge grubs, there being one at each plant so cut down. We tried the gentlemen by placing them on quicklime and covering them with it, and also with soot, &c.; but we might as well have regaled them with tea and toast, for after a couple of hours they were as ready for a nibble as ever. We know no effectual remedy for this enemy except catching the fellows after they have done the mischief, and treating them as the law is obliged to treat the most incorrigible wrong-doers. All sorts of baits, and traps, and enticements we have found to be of very partial efficacy. Our next enemies are either hares or rabbits, and we are as yet afraid to hunt much for them, especially with dogs, in case they should chase them into our flower-beds, from which these Cabbages are merely separated by a dense Ivy hedge; for now, with the exception of two or three beds of Calceolarias, from which the flowers have been dashed without succession enough to cover them, the flower garden is as good, or better, than it was in July and August.

Watered Celery well; earthed-up a little bit more, so as to have plenty for table, stewing, &c. On clearing some Peas, planted-out several beds, placing the plants about 9 inches apart, as we do not expect them to be very strong, but they will be useful in the spring months. In planting such beds we do not take out much soil—little more than the manure fully fills up, or rather more, as in stiff soil late Celery suffers more from damp than from cold and dryness. Early Celery, on the other hand, when it bolts and runs, and is only fit for soups, if even for that with particular people, generally does so from dryness, and this dryness is frequently, if not generally, the result of earthing-up Celery bit by bit, an inch or two at a time. The reasons were given in this Journal some years ago. When treated as there stated we have seldom had a single head of early Celery run or bolted. Some amateurs and the holders of small gardens can scarcely credit the economical question involved in the Dwarf Incomparable Celery. Well, all we can say is that we speak of it as we find it; and merely on the score of economy we think a foot of earthing-up, or even

less than that, a very different affair from the huge mounds and trenches generally given to Giant Celery. If our adviser "A. Z.," with his few rods of ground, still prefers the Giants and the mounds, why, of course, we have no fault to find, as we always advocate that every man has a right to his own individual fancy or whim so long as he indulges it at his own expense.

Took up our last row of Potatoes, the Dalmahoy, and found an extraordinary crop—some thirty good-sized tubers, and some, too, large at a single root. The tops, however, were gigantic, and in our close cropping we would have had more than two rows of Early Frame or Ashleaved Kidney in the same space. Here, too, we found a few cases of slight disease; whilst all that were taken up before the drenching rains were sound. Filled all the spaces vacant with Brussels Sprouts and Cottagers' Kale, lifting those that had been previously pricked-out; and, notwithstanding our killing many butterflies, found a good many caterpillars on them, and, therefore, dusted them well with lime and soot, and scattered it well below the leaves with a small birch broom before planting them out. Went over young plantations of Cauliflower, Broccoli, and other Greens in the same way; as, unlike the grub, very little of the caustic lime does for the caterpillars. Planted-out more Endive, and covered some of the forwardest with pots, tiles, and slates—anything just to keep the light from it. Short boards, 9 to 12 inches wide, laid along the rows answer admirably. Sowed a few more Lettuces, and watered the young Cauliflower plants not yet large enough to prick-out. Prepared a slight hotbed for our Mushroom spawn, making it about 6 feet square and some 15 inches deep, so as just to throw in a mild bottom heat. Placed a piece of old latticed fence over the bed to keep the spawn-bricks from the hotbed, and having inserted a small piece of good spawn in the two holes of each brick, and covered over with stiff cowdung to keep the spawn in its place, commenced building the bricks in an obtuse cone, leaving about an inch from brick to brick, so that the heat should circulate freely between them; then covered all with a little clean straw, and placed a foot of littery manure that would yield scarcely any heat over all. This heap will require examining frequently, as the heat should not be more than from 70° to 75°. If some bricks be thoroughly permeated before the rest they must at once be taken out. Even when the spawn is running freely much overheating will render nugatory all the previous labour.

FRUIT GARDEN.

Much the same as last week. Will take means for keeping heavy rains from early Vine-borders and those in which Vines are now ripening their fruit. Have been obliged to fill our late house with plants, owing to the necessity of repairing and altering the house in which they were kept. Gave more heat and air in consequence. Gathered fruit as it ripened. Pears are now swelling freely, though the roots are scarcely moist enough.

ORNAMENTAL DEPARTMENT.

Much the same as last week. Pricked-out annuals, perennials, &c. Tree Carnations planted out for winter-flowering should be lifted before the end of the month with balls, and placed in pots that will just admit the balls. Flakes and Pinks to be forced cannot be too well established in the pots before placing them in gentle heat. Anne Boleyn Pinks and most Cloves and Carnations will bloom naturally in the autumn and winter months under glass without any heat worthy of the name of forcing, if they are prevented blooming in summer, by taking off the flower-stems as they appear. When we used to have huge masses of the Perpetual Carnations in winter, in a low-temperated greenhouse, we never allowed a flower-stem to show until towards the end of August. The most splendid beds of Perpetual Carnations we ever saw we used to have in August, September, and October; but, of course, they were not stopped, and they were useless for spring and winter work. We regret now that other plants becoming favourites we let these fine flowers slip through our fingers, which must often be the case in places with limited room and where there is a constant contest going on between old and new combinations. When *Salvia fulgens*, splendens, and *gesneriflora* are planted out for winter and spring-flowering, they should now be lifted, potted, and placed in a shady

place, watered but not deluged afterwards, and syringed in sunny days to prevent excessive evaporation from the leaves, until the roots are working freely into the little new stuff round the sides of the pots. When Chrysanthemums are planted out in a similar way, it is best to defer the lifting and repotting until the flower-buds are formed, and treated as advised above they will hardly lose a leaf. This is, on the whole, the easiest way for obtaining good specimens with strong healthy foliage down to the sides of the pots.

Rolled the lawns, as the dry weather now after the late soakings has brought the worms and their heaps in masses to the surface, making, from the roughness, a lawn disagreeable. We fancy the worms do not relish the rolling, as it seems to make them descend instead of ascend. The safest mode of keeping them at bay is deluging with lime water two or three mornings after rolling, for then the fresh holes will be all open—a plan very suitable for small grass plots, but hardly practicable on acres of grass. Though they have not yet appeared, we may expect heaps to be raised by the worms at the sides of fine walks, thus disfiguring the regularity of their outline, and for their prevention we know nothing better than strewing the sides with fine-pounded salt. Recollect we say the sides—say for 6 inches wide, for we would never salt a walk at all smooth at this season without expecting to find it damp and uncomfortable all the winter through. When a walk is very rough on the surface the salting will be less injurious. Walks in general—that is, moderately smooth ones, in our opinion should never have salt after midsummer; and as to applying it, we have found no plan preferable to strewing it on the gravel in a hot sunny day, and when several of such days may be expected. Of course, by this plan the walks do not look so nice for several days as when the salt is applied with hot or cold water at once.

Went over the flower-beds once more, regulating, picking decayed blooms, &c.; and were it not for a few leaves flying about from trees, and which begin to drop early from the great drought, the flower garden as a whole shows no signs of autumn. Some two or three masses of *Aurea floribunda* *Calceolaria* that were excessively thick with bloom have suffered most from the rains, as the roots were very dry at the time, and though plenty of blooms are showing it would require fine weather to render the masses equally fine again. Such kinds as *amplexicaulis* and *Aurantia multiflora* have suffered but little and are still gay with seemingly abundance of succession flowers. One light brown kind called Robert Burns, a good deal like the brown Prince of Orange, and that was scarcely so good as the latter in the first part of the summer, is now much better. Such small dark kinds as *Victory* suffered greatly from drought, and we fear the rains came too late to give us an equally dense amount of flowering. Such kinds as *Crimson King* have suffered less. On the whole the *Calceolarias* have suffered less than we could have expected from such dry weather as we had, and no water to help them with. No season could have been better for *Scarlet Geraniums* of all kinds, and we do not think we recollect ever seeing them better. With ground pretty well stirred at first they scarcely require any water after being once established. The only regular failure we had owing to the dry weather and scarcity of water, was with the *Grandiflora white* *Feverfew*, which was first-rate with us last year up to the end of October. This, placed in a position of honour in a ribbon-border, between *Trentham Rose* *Geranium* and *Perilla*, became too shabby for its position, and a few weeks ago we cut or covered it up by drawing the *Perillas* and *Geraniums* close together, and so completely filling the space that no visitor would think otherwise than that the border was planted exactly as it looks now; and some who did know think that it is much better as it is, though we do not think so ourselves, as the white seemed to us to relieve both masses of colour better than when placed as now in juxtaposition.

Went on putting in a fresh batch of *Verbenas* in 48-sized pots, only a few being put in at first into 60-sized pots; these are now rooting freely. They stood on the ground with a frame over them, and during the heavy rains were deluged by the rain passing through the frame. A bed of litter was made, and ashes put on the top for the pots to stand on, and drain-tiles were placed between the litter, so that in future downpourings the rain will pass through

beneath the bed, instead of soaking into it. Had they remained long in their first position, and the rains had continued, no amount of air would have prevented damping. Our attention is still given to cuttings of *Geraniums*: even taken with the greatest care, the beds are apt to be disfigured more or less, showing the necessity of reservelands for this purpose. We will prepare a cold pit for *Calceolaria* cuttings as soon as possible, but the middle of October, if there is no frost, is quite time enough for the general crop. A few rare kinds may be propagated sooner, and topped to make plants, but much of the success in summer, we think, depends in not striking the cuttings too early, and never allowing them the least artificial heat. Other departments much as previous weeks.—R. F.

DEATH OF MR. HUGH LOW.—We regret having to record the decease of this distinguished florist and nurseryman. He died on the 15th inst., at the Clapton Nursery, in his 70th year.

COVENT GARDEN MARKET.—SEPT 19.

Of vegetables and fruit of all kinds the supply continues abundant, both from home and abroad. Pears and Plums are very plentiful, the former consisting principally of *Williams' Bon Chrétien*, and *Loise-Bonne* of Jersey, and some *Marie Louise*. Filberts are in good condition; and Cobs are bringing from 55s. to 70s. per 100 lbs. Oranges and Lemons are scarce, and prices have risen. Potatoes are very abundant, and also very good, prices having a downward tendency. Cut flowers consist of *Orchids*, *Roses*, *Asters*, *Felargoniums*, *Marigolds*, *Mignonette*, and *Ageratum*.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

FERN LEAVES FADING (*H. B.*).—The change of colour is a consequence of growth-completed. It is natural change, not from disease.

HARE'S-FOOT OR DEER'S-FOOT FERN (*A Constant Reader, Dublin*).—It is not indigenous in England, nor is it found anywhere in a wild state where we know, except in the South of Europe, North Africa, and the Canary Islands.

COTTAGE GARDEN EXHIBITIONS (*S. D. S.*).—If you will send us an envelope directed to yourself, and with a 2d. postage stamp, we will lend you a pamphlet on the subject.

TWELVE HARDY HEATHS (*H. C.*).—You will find the following very good for a border:—*Erica australis*, *herbacea*, *herbacea carnea*, *cinerea alba*, *cinerea rubra*, *mediterranea*, *mediterranea hibernica*, *stricta*, *tetralix rubra*, *vagans carnea*, *vulgata alba*, *vulgata coerulea*. To the above you might add *Menziesia globularis*. There are other varieties also, all good in their way, but enough has been given to form the nucleus of a collection. Perhaps the most useful of all are *E. herbacea carnea* and *E. mediterranea*, but all are beautiful.

HOUSE FOR WINTERING BORDER PLANTS (J. F. S.).—Your span-roofed house 30 feet long would answer admirably for preserving border and bedding plants. You can make it economically by putting up a plain and simple structure, employing but little woodwork, and having large panes of glass. Provision must be made to admit abundance of fresh air. After bedding plants are cleared out you could either have ornamental Cucurbitaceae or useful by growing Cucumbers or Melons, or if you could make a border conveniently, you might have a crop of Grapes in September. Excellent Melons could be grown in such a house by merely making a bed and training the plants to wires fixed about 1 foot from the glass. Success would be more certain with a pipe under the bed. One four-inch pipe would not be sufficient for top heat to keep out an ordinary winter frost unless the house were very narrow indeed. Two four-inch pipes across one end and along the front would be necessary for a house 10 feet wide, and two four-inch pipes all round if it exceeded 15 feet in width. We should prefer pipes for bottom heat instead of a flue, and as you think of having a boiler we do not see the necessity for a flue at all, except it were to economise heat, when you might have a flue in addition to the pipes for top heat, and so make use of the heat that necessarily escapes from boilers, and which would, were there no flue, pass into the chimney and be lost. It is not unusual to carry pipes under a path; but this is best done after the pipes have risen from the boiler some distance, when by an elbow they may be carried under any path not lower than the opening in the boiler for the return-pipe. Pipes are commonly brought under paths by setting the boiler so that the flow-pipe will rise a little, but still be lower than the pathway. The flow-pipe should rise from the boiler about 1 foot in a 30-feet house to the extremity, when it may fall in the return to suit the opening in the boiler for the return. You may carry the flow-pipe any height above the boiler, but it will work as well with a rise of 1 foot in 10 yards as with a rise of 12 yards in that distance. It is not usual nor necessary to carry the pipes up and down and up again, though they may be done in that way so long as this up-and-down work is not permitted to interfere with the circulation. It will not do to take the flow-pipe up and then down below the top of the boiler, and up again: the water will not circulate in that way; but, after it once falls below the top of the boiler, the pipes must be carried from that point to the bottom of the boiler. We should recommend you to have a saddle boiler, and if you send a plan of your house to the dealers in hot-water apparatus who advertise in our columns, they will send you a small boiler capable of heating your house well at a small sum. The smallest saddle boiler made will be sufficient to heat the 80 feet of piping you will need for top heat, and for the 30 feet of pipe for bottom heat.

PEACH-HOUSE (O. M.).—For a Peach-house we should continue the vinery range at a, making it any length, but the same width and elevation as the vinery. If your boiler is powerful enough a branch might be connected with the flow-pipe heating the vinery to heat the Peach-house, connecting the return with that of the vinery. For a Peach-house the trees do best planted out. The border can be both inside and outside, or either separately. We do not think there is much difference between growing Peaches in pots or planted out in a border; but the amount of trouble required in watering trees in pots is double that for those planted out. If you desire variety, have an orchard-house; if but a supply, we should advise you to have a Peach-house. A span is best for an orchard-house, and it would be most sheltered, we should say, at a. It might be at a; but that, of course, would receive the full violence of a south-west gale. We are much obliged for your notes on *Centaurea candidissima*.

SOWING SEEDS FROM INDIA AND CHINA (M. H.).—We presume you had the seeds without names. Had you the names with them it would have better enabled us to answer your queries had you sent them, for there are so many plants from those countries that require a diversity of treatment to meet their wants. Some may be annuals, others trees or shrubs; one may need peat soil, another loam, whilst a third would do better in a mixture of both. Had we such a packet of seeds we should make a kind of universal compost composed of one-fourth dry peat, a like quantity of leaf mould, and one-half mellow loam from rotted turves, with a liberal sprinkling of white sand. This, well incorporated and sifted, will grow almost any description of plant. You will well drain the pots in which the seed is to be sown, and fill them with the riddled compost to within an inch of the pot-top or rim for seeds the size of a pea, lessening or increasing the depth according to the size of the seeds; place these so that they may be double their diameter from seed to seed, and cover them with soil to the same depth that the seeds are respectively in diameter. The seeds larger than peas had best be sown in single pots—that is, one seed in each. You will do this sowing business in March of next year; and all being sown, place those from India in a little bottom heat, if you have it, in your stove, and those from China in bottom heat in the greenhouse, or place them all in a bottom heat with the bottom heat at 75° or 80°, but not exceeding 85°. When they are fairly up and begin showing their rough leaves remove the Chinese to the greenhouse and the Indians to the stove, placing them in the warmest part of each respectively for a few days, gradually hardening them. Water sufficiently to keep the soil moist, and when they have made a pair of rough leaves pot them singly if strong growers, or put three, five, or more round a small pot if moderate growers, and report them again so soon as the roots reach the sides of the pot. Continue to do this until the plants become established, when we should advise you to call in some friend who has a good knowledge of plants, who in all probability would be able to assist in naming them for you; and if you look in our Journal you will be sure to find information how to proceed with them if they be plants worth cultivating. We are very cautious, however, about sowing seeds that we know nothing about, for it is very mortifying to fill our houses with what often is rubbish.

GRAPES SHAKING (G. J. H.).—We have little doubt that the Vine-roots, robbed of nourishment in "the very shallow surface soil by the roots of the shrubs, &c., grown in the border," have been driven down for a supply of food into "the stiff heavy marl which is the subsoil." If you cannot clear away the shrubs, &c., and lift the roots of the Vines to near the surface, your next best plan will be to enrich the surface soil, and keep it mulched and well watered during dry weather in summer. The exclusion of the sun's rays from the soil in which are the Vine roots is very prejudicial, because during the growing season they must be too cold to keep pace with the demands for growth in the branches.

PINE-APPLE CULTURE (John Forrester).—Glendinning's "Practical Hints on the Culture of the Pine Apple," will suit you. It was published by Messrs. Longman & Co.

FLUE HEATING A GREENHOUSE (Clericus).—We think the way in which you propose to heat your greenhouse would do. It would be an improvement to bring the flue from the furnace at A under the path, so that the door would open to the front of the house, and then along the front, then across the other end to B, where it would make its exit in the chimney. For so narrow a house it does not matter much where the flue is situated, only the heating surface as a rule should be placed where the roof is lowest. The furnace need not be larger than 1 foot 6 inches long, 10 inches wide, and the same in depth. The flue should not be more than half the furnace dimensions. Six-inch pot-pipes with the joints mortared will suit you. The fire should rise from the furnace the height of the furnace into the flue. It may then run nearly level to the chimney.

FLOWERS TO BLOOM SIMULTANEOUSLY (Mrs. C., Sidmouth).—The four large beds now occupied with Scarlet Geraniums and to be planted with *Tulban Ranunculus* will be charming next May; but those filled with Crocuses and Tulips after purple Verbenas and yellow Calceolarias would no doubt look well individually, but we should only deceive you if we were to say they would flower simultaneously with the *Ranunculus*. We should advise you to plant the scarlet *Tulban Ranunculus* early in November, and edge them with striped Crocuses, as *La Majestueuse*, *Fride of Albion*, and *Sir Walter Scott*. In the yellow beds we would plant *Yellow Rose double Tulips*, and edge them with yellow Crocuses. The purple beds may be planted with *Aubrietia purpurea grandiflora*, a hardy perennial, edged with purple crocuses. The Crocuses would make the beds gay in March and April, and the other occupants might be expected to flower pretty nearly together. We do not know of a purple or any other description of Crocus that flowers simultaneously with the *Ranunculus*. You will plant the bulbs as early in November as convenient.

FERNS FOR GLASS CASE (H. F. L. K.).—Of Ferns suitable for a Fern-case in a room never below 45° in winter—*Adiantum a-simile*, *A. curvatum*, *A. cucullatum*, *A. reniforme*, *A. pubescens*, and *A. setulosum*. Suitable for a small hanging-basket—*Asplenium appendiculatum*, *A. Belangeri* (Veitchianum), *A. bifidum* (funiculaceum), *A. decussatum*, *A. formosum*, *A. ebenum*, *A. monanthemum* and *A. monanthemum proliferum*; *Blechnum gracile*, *B. australe*, *B. latifolium*, *B. occidentale*, and *B. lanceolatum*; *Campyloneuron angustifolium*, *C. rigidum*, and *C. Fortunii*; *Davallia dissecta*, *D. canariensis*, and *D. tenuifolia*; *Doodia* (*Woodwardia*) *aspera*, *D. caudata*, *D. lunulata*, and *D. media*; *Doryopteris palmata* and *D. sagittifolia*; *Lastrea acuminata*, *L. glabella*, and *L. decomposita*; *Lomaria alpina*, *L. nudula*, *L. Patersoni*, and *L. L'Hermierii*; *Acrophorus* (*Microlepia*) *nove-zealandica*; *Nephrodium molle corymbiferum*; *Nephrolepis pectinata* and *N. tuberosa*; *Notholaena lendigera*; *Pellaea flexuosa*, *P. geraniifolia*, and *P. filifolia*; *Pleopeltis perussia*, *P. stematica*, and *P. pustulata* (the two last are the sort of Fern to plant in the ba f of a cocoa-nut shell and suspend from the roof); *Platycentrum alcornoce* (this is extremely beautiful treated in the same way as the two last); *Platyoma falcata* and *P. rotundifolia*; *Polystichum triangulum* (*mucronatum*) and *P. vestitum*, rare; *Pteris cretica albo-lineata*, *P. serrulata*, *P. crenata* (*chinensis*), *P. scaberula*, and *P. tricolor*; *Scolopendrium Krebsii*; *Stenosemia aurita*; *Tamopsis* (*Vittaria*) *lineata*; and *Xiphopteris* (*Grammitis*) *serrulata*. All the above are handsome, distinct, small or moderate-growing species; but the handsomest of all for a Fern-case are the Filmy-Ferns, as *Todea pellucida*, *Hymenophyllum demissum*, *H. abruptum*, *H. flabellatum*, *H. flexuosum*, &c.; *Trichomanes elongatum*, *T. reniforme*, *T. venosum*, *T. crispum*, and *T. radicans* or *T. speciosum*, the Killarney Fern. These require a humid atmosphere. Nearly all Mosses are suitable for Fern-cases: of them we may instance *Selaginella uncinata*, *S. africana*, *S. densa*, *S. apoda*, *S. jamacensis*, *S. obtusa* (*helvetica*), *S. denticulata*, *S. erythropus*, *S. viticulosa*, *S. Wildenovi*, and several others. The seven preceding the last are beautiful for suspending in small baskets or cocoa-nut shells in the Fern-case. All except the Filmy-Ferns require peat one-half, leaf mould and light loam in equal parts, with a liberal admixture of silver sand. Good drainage must be provided if they are expected to thrive long. They require to be kept moist in winter and wet in summer, and are planted like any other plant. Cocoa-nut dust, with a little loam added to it, is the best of all composts for Ferns. Our "Fern Manual" contains full particulars of their cultivation.

LEAN-TO HOUSE FOR FERNS (An Irish Subscriber).—We should prefer an angle of 45° for the roof, which, with a wall 6 feet high to the north and a 15-feet rafter, with one end of it fixed on the north wall and fastened at top to the greenhouse wall near the top, would give an angle of 45° nearly, and make the house some 12 feet in width. You can have it wider by having the roof flatter or less steep. There is no necessity for any lights in the back wall, and you can ventilate it by having slide lights at top or to lift up, having about half the number you would employ for an ordinary greenhouse. We think your other arrangements would do very well, except the mode of heating, which we fear would not answer unless you grew hardy Ferns, which you, no doubt, do not intend to grow in-doors. The openings in the back wall will not admit sufficient warmth in winter to keep the frosts at bay; therefore, you must have at least a couple of four-inch pipes along the lowest part of your fernery. Shelves formed of peat are quite a novelty, and no doubt answer well; but we should think that if a lockery were formed and the Ferns planted out you would like it better. You can have the house any width—the wider the more it will cost; but, irrespective of that, we would have it 12 feet. Such a house will require shading with canvas, or some material, from April until October in bright weather.

FOUL ASPARAGUS-BEDS (Idem).—Fork out the couch grass at once, but do so without injuring the crowns of the Asparagus. By no means must it be left a day longer, but fork it out whenever it appears and pull up all weeds forthwith, and in after years never let a weed stand an hour after it is visible or large enough to pull up. It would be a pity to take up the Asparagus, for it would not thrive well if planted again, and unless you have many beds your supply would be cut off for three years at the least, in addition to incurring unnecessary expense in making new beds, &c.

CUTTINGS OF VERBENA TRIPTYLLA (M. F.).—This Verbena may be planted outside in June, and taken up on the approach of frost. Cuttings strike freely in loam and leaf mould, with the addition of a free admixture of silver sand, selecting cuttings of the half-ripened shoots and placing the cutting-pots in a little bottom heat. They root more tardily, but without many failures, in the greenhouse; and we have struck them in the open border under a hand-glass.

BRICK STOVE FOR A GREENHOUSE (H. H. M.).—Fire-bricks are 9 inches long, 4 inches wide, 2½ inches thick. Fire-jumps are 9 inches long, 9 inches wide, 4 inches thick. The latter are the most durable, as the mortar burns

out of the joints of the bricks. In your small house an 18-inch stove would give heat enough, but the Arnot principle in the fire-box must be departed from. This will not be of consequence in so small a house. The feeding-door may be on hinges; the draught-door should slide.

NAMING FERNS (*G. P. H.*).—To name forty species would take a large portion of a day, and we cannot spare the time. You are not far from Foot's Cray if you live at the Kent Stroud; and if so, go to Mr. Sims, nurseryman there, and ask him to let you compare your specimens with his.

NAMES OF FRUIT (*W. W.*).—2, Williams' Bon Chrétien; 3, rotten.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (*W. H. M.*).—1, *Athyrium Filix-foemina*; 2, *Polypodium phegopteris*; 3, *Athyrium Filix-foemina depauperatum*; 4, *Polystichum aculeatum*; 5, *Lastrea temula*. (*C. M. M.*).—*Pteris aquilina* in the seedling state. (*E. S., Hampton*).—It is a *Canna*, but there are now so many continental varieties grown that we cannot, without means of comparison at hand, attempt to say which.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BRAHMA POOTRA MERITS.

In your paper of September 8th, I was very glad to notice an article from "Y. B. A. Z.," on the relative merits of Brahma Pootra fowls at the various poultry shows, as compared with other breeds. In this part of England—viz., the north, they have never been classed separately at any show this season, except the Halifax and Calder Vale; and as proof that they ought to take their station on an equality amongst other breeds I submit you an abstract from the catalogue:—

Breeds.	No. of entries.	Amount offered in prizes.	Amount obtained by entries.
		£ s. d.	£ s. d.
Spanish	17	3 10 0	2 11 0
Dorkings	19	3 10 0	2 17 0
Cochins	34	3 10 0	5 2 0
Brahmas	21	3 10 0	3 3 0
Game (Black-breasted)	29	3 10 0	4 7 0
Game (Duckwing)	19	3 10 0	2 17 0
Game (Any variety)	18	3 10 0	2 14 0
Polands	15	3 10 0	2 5 0
Gold-pencilled Hamburgs	17	3 10 0	2 11 0
Silver-pencilled Hamburgs	13	3 10 0	1 19 0
Gold-spangled Hamburgs	12	3 10 0	1 16 0
Silver-spangled Hamburgs	14	3 10 0	2 2 0
Any other distinct breed	6	3 10 0	0 18 0

You see by the above that the excluded Brahmas stand third on the list as being profitable to agricultural and poultry societies. They have not previously had the chance to come forward, and yet when the inducement is offered how freely they respond. This, I am sure, ought to influence compilers of schedules.

I have kept Brahmas for the last ten years both in England and America, and I have come to the conclusion that they are the most profitable fowl any amateur can keep; and for the table I consider there are none to equal them, and yet they must be excluded from almost all poultry shows as a class. Have they not been sufficiently long before the public to merit better treatment? and have they not stood their ground, yea, and worked themselves up steadily but surely against all difficulties thrown in their way? But I anticipate for Brahmas a brighter prospect for the future. They will eventually stand at the head of all breeds; at least that is my opinion.—A YORKSHIRE POULTRY-FANCIER.

EASINGWOLD AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE third annual Show of this Society was held at Easingwold on Tuesday, September 15th, and considering it is a young Society and the district it is in, there was a fair show of poultry.

The following is a list of the awards:—

SPANISH.—First withheld. Second, J. H. Dee, Easingwold.

DORKING.—Prize, F. Wailes, Easingwold.

COCHIN-CHINA.—First, J. Jackson, Crayke. Second, — Naylor, Oswaldkirk.

GAME (Any variety).—First, Lady Julia Wombwell, Newburgh Park (Brown Red). Second, J. Wilson, Upperly, Easingwold (Black Red). *Chickens*.—First, J. Bell, Thornton-le-Moors. Second, R. Midgley, Sheriffrutton.

POLANDS.—First, S. Flint, Primrose Hill, Easingwold.

HAMBURGERS (Golden-spangled).—First, L. Mackfield, Thirkleby. Second, R. Windsor, Atpleforth.

HAMBURGERS (Silver-spangled).—First, Mrs. Tarbotton, Cawton, Gelling. Second, L. Mansfield, Thirkleby. Highly Commended, G. Hodgson, Raskelfe.

ANY OTHER VARIETY.—First, H. Thompson, Sheriffrutton. Second, J. P. Wardman, Easingwold. *Chickens*.—First, W. J. Ware, Skirpenbeck. Second, J. Bell, Thornton-le-Moors. Highly Commended, F. Wailes, Beacon Banks, Easingwold.

GESE.—First, F. Wailes. Second, J. Jackson. Commended, W. Temple, Raskelfe. *Goslings*.—First, J. Jackson. Second, W. Temple. Highly Commended, K. Wood, Yearsley.

DUCKS.—First, E. Brown, Easingwold. Second, T. Dinsdale, Easingwold. Highly Commended, Miss Kirby, Osrodby. *Ducklings*.—First, J. T. Robinson, Thormaaby Hill. Second, E. Latty, Tollereton.

TURKEYS.—First and Second, J. Latty, Stillington Lane. *Poults*.—First, L. Daston, Cranley. Second, W. J. Ware, Skirpenbeck. Highly Commended, W. Milner, Thornton Hill. Commended, J. Jackson, Crayke.

The Judges were Mr. Alexander Cattley, York; and Mr. George Barker, Scarborough.

DOUBLE-SIDED WOODEN HIVE.

WOULD a bee-hive of the following description be likely to answer in this variable climate for an out-door apiary?—viz., an inner hive made of wood 1 inch in thickness, eight-sided of course (the size of the hive may be made according to taste), with an outer hive made also of wood three-quarters of an inch in thickness, but large enough to admit of a space inside 1½ inch wide all round after the inner hive is placed in it. The two hives to be fastened together by means of pieces of wood screwed to the bottom, and also to the top of the edges of each hive; the space between of 1½ inch to be filled with sawdust, the bees of course occupying the inner hive only. I have devised this kind of hive, not being satisfied with the straw hives we buy in this part of the country (Hants). Where can I obtain a prime swarm of Ligurian bees in the spring?—AN OLD SUBSCRIBER.

[There can be no doubt of a hive of this description being an efficient nonconductor, but it made with such thick wood it would be exceedingly heavy and clumsy. We think that on this account it would be best made of half-inch wood throughout. For information respecting Ligurians write to T. Woodbury, Esq., Mount Radford, Exeter.]

LONGEVITY OF A QUEEN BEE—FOUL BROOD.

IN reply to "A HAMPSHIRE BEE-KEEPER," as to the age of a queen bee, I beg to say that there was no supposition in the case, and to answer him in the affirmative, it is beyond my skill, but, perhaps, I might answer him in the negative.

He says that he uses the fungus at all seasons of the year. Need we then wonder at his short-lived queens? Although they appear to recover from the stupifying, I fear it is only a partial recovery, and that until he uses a more humane mode of managing his bees he may expect very little success. No scientific bee-master that I know ever kills or fumes his bees.

The best hives I have this season are three, in which the queens' ages are three years and four years old. In the middle of June these hives weighed only 25 lbs.; but the weather setting in fine, on the 17th of July I took from each 20 lbs. of honeycomb, and again on the 26th of August I took on an average from each 38 lbs. of heather honeycomb, besides leaving two of them 33 lbs. each, and the other 52 lbs.

I would very gladly bargain with "A HAMPSHIRE BEE-KEEPER" for one of those queens I have mentioned, for the purpose of experimenting upon, and I shall expect and be glad to hear of his having queens proving themselves fertile at more than two years old.

I have already stated that foul brood arises from the queen producing more than the bees are able to attend to when a change of the weather takes place; but although this I consider the most general cause, there are other causes producing the same effect.

For example: In August, 1857, I saw several instances of foul brood, which arose from the extreme heat and the want of ventilation or extra room: consequently, almost the whole of the bees evacuated their hives, and clustered on the outside, thereby leaving their young unattended. The result was a polluted hive.

Again: I have seen the same disaster occur when bees had been induced by feeding to breed earlier than they were

wont to do, and then the feeding was discontinued, the bees not having store enough of their own to carry through the breeding process; so that the larvæ are not supported by proper food, and are constitutionally in a consumptive state.—A LANARKSHIRE BEE-KEEPER.

TWO QUEENS IN ONE HIVE—FOUL BROOD.

MR. WOODBURY'S mystery of a supernumerary queen I consider no uncommon incident in a hive, and had he allowed her to remain he would have seen the rightful sovereign expelled to a certainty. I may just give an instance which occurred recently here in the apiary of a Mr. B. This gentleman had a queen expelled from a hive in the middle of the honey season, and she being to all appearance perfect, he was determined to lose no opportunity of watching the future proceedings of this hive. When, to his astonishment, on the same day he had the pleasure of seeing a young queen take wing, and she afterwards turned out exceedingly prolific.

I heartily agree with Mr. Woodbury's opinion on foul brood, and look on Mr. Lowe as being quite at sea when treating it as an artificial disease. I have seen it in the most virulent form in the cottager's apiary, as well as in the apiary of the scientific bee-keeper.—STEWARTON APIARIAN.

[I am perfectly aware that a supernumerary queen in a hive is no unprecedented occurrence during the swarming season, and quite agree with the "STEWARTON APIARIAN" as to the probable dethronement of the rightful monarch if the interloper had been suffered to remain. Two similar cases have in point of fact already come under my observation, but both these, like that instanced by my Ayrshire correspondent, occurred in the middle of the honey season. As stated in my former communication, what excited my astonishment was finding a second queen so late in the season with no drones existing in any of my hives, and in a colony reduced to the condition of a recent swarm.

With regard to foul brood, it is very satisfactory to have a verdict in my favour emanating from so high an authority in what our Renfrewshire friend designates as "the great centre of bee-knowledge;" and I should be greatly obliged to my Stewarton correspondent if he would favour us by relating his experience of this disease which has enabled him so decisively to confirm the testimony of—A DEVONSHIRE BEE-KEEPER.]

RANDOM APIARIAN NOTES.

THE HONEY OF 1863.—The honey taken this season is not so delicate and nice in flavour as that even of the unpropitious year, 1861. There was some honeydew one whole week, at the commencement of July this year. Probably, this might have been the cause, or was it the three weeks wet weather in the main honey-gathering month of June? The quantity is far above what was expected.

MR. WOODBURY.—I have been found fault with for some observations on Mr. Woodbury's bee-management. I am not aware of saying more than that I was sorry for his failures. Indeed, I admire him for his honesty in confessing them. If the writers on bees had been as faithful as Mr. Woodbury, we should not have been inundated with those theoretical treatises which have talked of the most tedious and difficult experiments as perfectly easy; and in particular that of depriving a stock of bees of the whole of their combs, forcing them into a new and empty hive and making them begin *de novo*! How often has this succeeded? I never saw it done where desertion did not take place soon afterwards with ruin and loss of the bees. A too great deprivation of the combs will also bring on the same misfortune. I can assure your correspondent "B. & W.," that fifty years ago I was fond of trying experiments with bees, and was only now and then successful; but of late my patience has been exhausted, and I am quite content with bee-keeping in the old-fashioned style; at the same time I may add that "B. & W." has said nothing but what is strictly true of Mr. Woodbury. The latter I hope to see rise like a Phoenix and shine in a prosperous cycle of fine summers, and continue after a long life at the top of the list of the "scientific apiarians" in England; and to "B. & W." and the other

experimental bee-keepers. I only say, Go on in the pursuit of that interesting study. By the way, I strongly recommend to "B. & W." a perusal of the seventh and eighth Volumes of THE COTTAGE GARDENER, where may be read some excellent letters signed "A COUNTRY CURATE," now, I believe, a beneficed clergyman. The "COUNTRY CURATE" was then an experimental bee-keeper and would not allow of many failures. "B. & W." will also find in those Volumes a good many letters from another bee-keeper of the "old school," who continues still to send a few communications to THE JOURNAL OF HORTICULTURE.

BREEDING.—The breeding has been continued in some of my hives up to the 24th of August. On the whole the bee season has certainly been an eccentric one. A swarm of this year of the 23rd of May hatched their drones about the 28th June; these were all killed. In the last week in July the hive became so crowded that the bees hung outside. Thinking it too late to put on a super, I allowed them to take their natural course, when one fine gleamy afternoon (29th July), about 2 p.m., they suddenly threw off a swarm; but it was a very small one and being so late not worth living; they went into an old weak stock.

ROBBER BEES.—My weakest swarm, hived on the 12th June; a second swarm or "cast," have been attacked by robbers from a distance, as I named in a former communication, but on Monday, August 24th, they were attacked in my absence by several thousands of these marauders and regularly overpowered. On my arrival at three o'clock, the young swarm commenced leaving the hive in a body, the robbers remaining in possession. I destroyed several hundreds of the latter, but the whole of the honey was carried off; and the wasps, which are now numerous, finding that a scramble was going on, assisted the robbers.

WASP-GLASSES.—I have found these very effective. They are advertised in THE JOURNAL OF HORTICULTURE by Messrs. Millington. I put simply brown sugar and water into these glasses, and they are now a quarter full of dead wasps. Not a single bee has been trapped; but if a tyro apiarian put honey or any other luscious liquid into these glasses the bees will be enticed directly.

TWO QUEENS IN ONE HIVE.—We have heard of two "Kings of Brentford," but it is a rare thing to hear of two queens living quietly in the same hive, as described by my worthy friend Mr. Woodbury. Probably the young one described by Mr. Woodbury might have been diseased or barren, at least for a time, and the bees have certainly a quick intuitive discernment of any defect. Place a really disabled bee on the alighting-board of a hive—one of the same bees I mean, of course, and the unfortunate wight is immediately destroyed; but place a poor benumbed one in the same place, although unable to crawl, but sound wind and limb, this bee is allowed to remain and enter the hive as soon as recovered. All real bodily defects are instantly discovered. Of course, all apiarians know that for many days, and even weeks, two and even three queens are frequently allowed during the swarming season in May and June; but in my two uncomb-hives, made purposely for observation, I never discovered but one queen laying eggs, and from seeing the queens so frequently could easily perceive that it was the same bee. This holds good generally from July to April inclusive, as to one queen only.

FOUL BROOD.—This is a disease among bees I have never noticed. It has been so ably discussed by the different writers, that I do not venture to enter the lists in the argument. All I have to say is, that if bees be well looked after, kept clean, not over-ventilated, nor kept too warm, nor confined in cellars, or shut up all the winter, disease will seldom or never attack them. Too much ventilation will prevent breeding and destroy the embryo brood in any weak hive of bees, and hence the hive gets in an unwholesome state. A very small swarm in a large hive seldom prospers.

AGE OF THE QUEEN BEE.—Your correspondent the "HAMPSHIRE BEE-KEEPER," should be referred to former Numbers of THE JOURNAL OF HORTICULTURE. It has been clearly proved that queens sometimes live three years, but I have always considered an old queen detrimental to a hive. Nothing like young blood for breeding and activity. An old queen often attempts an excursion and fails; hence at an unseasonable period of the year ruin comes on the stock.

KILLING DRONES.—I had a hive (a swarm of 1862), which

seemed to be overrun with drones. Whenever the bees are seen issuing out of their hives, collaring the drones or riding on their backs, there is no harm in assisting the bees. This being the case in the hive of mine alluded to in July last, I killed more than three hundred with my own hand, the bees destroyed about one hundred more. A drone-breeding queen is a disadvantage to a hive, particularly in a late season like the present, as I have before mentioned.

HONEYDEW.—Your correspondent "B. & W." seems to doubt the existence of honeydew during the month of July last. It commenced about the 4th and lasted until the 14th. It may be right to mention that the trees affording this exudation were mostly the oak, the beech, and the lime, besides various shrubs, particularly laurels and currant trees. It seldom takes place except in dry hot weather, and not only are the hive bees busy on this sweet exudation, for the *Bombix terrestris* and *B. lucorum*, and one other species of these wild bees are very busy on it too; and during the time it lasts, which is generally a very short period, the finest flowers are deserted and intense activity exists. There was honeydew in 1859, during the intense heat in July of that year, for a few days. The honeydew generally happens once in every four or five years, but sometimes not for seven years. From the year 1837 until 1842 I observed no honeydew; but in the splendid summer of 1842 I was then attracted in the middle of June by the louder humming of the wild bees among the young oaks and beech trees where no flowers or blossoms existed, and on examination I found the leaves of these trees covered with moisture quite sweet to the taste.

STUPEFACTION OF BEES BY FUNGUS.—I never heard of any good being done by this process, as in general one-third of the bees are rendered incapable of working again, and the remainder lose their *esprit du corps*. If all apirians had the perseverance of Mr. Woodbury, driving would be the best mode of operating when wanted. Mr. Cotton, whose pretty little book I have, stands up for the puff-ball fungus in most of his experiments, and denounces the inhumanity of killing bees, when, strange to say, a little farther on, talking of very weak swarms in the autumn and what to do with them, he says emphatically, "Feed them with a brimstone-match." The "HAMPSHIRE BEE-KEEPER" seems to have been more fortunate in his experiments than many of his "congeners" in fumigation. The county of Hants, take it altogether, is one of the best bee counties in England, and his bees ought to prosper well, particularly if he is within half a mile of heather.

Since writing the above observations I have read the remarks of the "HAMPSHIRE BEE-KEEPER" on honeydew, and they agree with mine, except that it is only in very peculiar seasons that honeydew appears so late as the month of August—once in fifteen or perhaps twenty years—and I have never noted much honey-gathering after the second week in July, except in 1848 and 1863—both rare exceptions. Indeed, in the present year there was more honey gathered in the first three weeks of July than I ever observed in this locality before at the same late period.

I shall conclude my remarks by observing that the summer of 1863 has been better than I ever expected, and I have never observed the honey-gathering and breeding continue so late in this locality as in the present season.—H. W. NEWMAN, *Hillside, Cheltenham*.

APIARIAN NOTES.

MY APIARY.—A long time has elapsed since I had the pleasure of sending any communication on the subject of "bees" for insertion in the pages of this Journal. To continued ill health during the spring and early part of the summer my silence must be chiefly attributed; but I must confess, that seeing from week to week that there was no lack of correspondence, or of useful and interesting papers on this subject, has made me feel less solicitous on the score of my own deficiency. But while my pen has been idle the bees have not, and their master has had plenty of work to do in managing and directing their labours to advantage.

Having successfully carried every one of my stocks through the winter, I found myself the possessor of nineteen stocks in March. In consequence of my Ligurianising efforts of last summer, and the great drain upon the population and resources

of the various colonies necessary in artificial queen-rearing, and substitution of Ligurian for common queens, together with the wretched season we experienced, the majority of my hives were remarkable for weakness rather than strength. Thanks to liberal supplies of artificial food in the previous autumn I found on inspection of the interiors of all my stocks in March, more or less sealed comb in every one. Some were very damp from internal moisture, but seemed little or nothing the worse for it; and these, on the whole, have proved to be my best and most prosperous colonies. From the ten-frame-hives I had in autumn removed a frame on either side, which I think is attended with much advantage both to the combs and the bees. These were wrapped in paper and replaced in the spring. Among the worst colonies in my whole apiary were the only two in straw hives, and these have done little for me the whole summer. These are old stocks, and probably have seen their best days. Two of the weaker lots in frame-boxes were united together, and with manifest advantage. In some the population was very scanty; but owing to the enormous breeding powers of their queens—possessing more or less of pure Ligurian blood—they ultimately became immensely strong, though not able to take full advantage of our first honey harvest in May. Notwithstanding that supers were supplied sufficiently early, several of my hives insisted on swarming; and what is more unfortunate, many swarms from some of my best hives were entirely lost. This is one of the consequences of keeping apiaries away from under the immediate personal care and supervision of the owner. Not a swarm was lost from the one consisting of seven hives attached to my own residence; but the bees in the two detached apiaries could not be always watched, and the loss of many fine swarms was the consequence. What renders this the more vexing is, that at the head of one of these fly-away swarms was a queen which bred the best-coloured Ligurians I had, and from which I fondly hoped to have raised some first-rate Ligurian mothers.

On looking over my note-book I find a few entries which may interest my apirarian friends. It will be best to give an epitome of my various stocks and what they have done. As a rule I have endeavoured to prevent all natural swarming, in spite of which I have had and have lost more swarms from hives so treated than has ever been my experience before.

No. 1. *Frame-hive*.—Artificial Ligurian swarm made on the 1st of June by removing one brood-comb with the queen, bees, and brood. June 15th strengthened by four frames of comb with honey and brood from No. 20. At this time a very promising stock. No honey has been taken.

No. 2. *Octagon Stevorton*.—Has not thriven all the summer, although a fine second swarm from No. 17 was added. I have feared that it is the victim of foul brood, but have not had time to examine it, being kept at a distance. Shall break it up at once if my suspicions prove correct.

No. 3. *Frame-hive*.—A fine Ligurian stock in the spring, but has not come up to anticipations. No swarm. About 22 lbs. of honey in supers taken.

No. 4.—Old stock in flat-topped straw hive, very weak and light in the spring. Uncertain as to whether a swarm flew away from it or not. Gave a nice glass of honey, 20 lbs. weight.

No. 5. *Frame-hive*.—A nice stock (common) in spring—a super put on in proper time—would not work therein, but chose to swarm. First swarm very good and saved. Second, believed to have been lost. No honey taken.

No. 6. *Frame-hive*.—Ligurian. Excessively wet internally when examined in March, populous, and great quantities of brood. Further strengthened by all the bees and some of the brood of adjoining hive No. 24 being united to it. A super put on and partially filled. An enormous swarm, which was saved, issued on July 11th. Honey taken, about 10 lbs.

No. 7. *Adjuster-hive*.—Common bees. In March extremely light, very dirty and wet. Hardly expected to save it; but it worked vigorously. Adjusting-super put on early; a very long time before the bees would construct combs, but have done well since the middle of June. About 35 lbs. of exquisite honey taken. The stock is heavy at the present time.—S. BEVAN FOX, *Exeter*.

(To be continued.)

OUR LETTER BOX.

CARRIER PIGEONS AT WAREFIELD POULTRY SHOW.—Mr. J. Frith who was awarded the second prize, lives at "Dewsbury," and not at Halifax.

BIRD MITES ON CANARIES (W. Alderley).—Fill every crack thoroughly with linseed oil, and dust flowers of sulphur among the feathers of the birds. Frequently and thoroughly cleaning out the cage is the best preventive of the pest.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 64.1°, and its night temperature 43.8°. The greatest heat was 80°, on the 4th, 1859; and the lowest cold, 17°, on the 2nd, 1853. The greatest fall of rain was 1.06 inch.

PLANTING AND SELECTING GRAPE VINES.

S the questions asked by "A YOUNG GARDENER" are of very general interest, it has been considered desirable to reply to them in a somewhat detailed form; for certainly there never was a time in the history of gardening when so many of limited knowledge and experience were so very commendably invest-

ing their funds and their time in the cultivation of the Grape Vine.

There are excellent works now in print on the subject, and much information has appeared in a periodical form; yet there will always be special cases where sound information connected with Vines and Vine-borders cannot fail to be interesting and useful, as in the case of our young correspondent.

Taking the questions which he has presented in their most natural order, the site on which the border is to rest comes first. The slope, or fall, of 12 inches and the concrete make an excellent beginning, and are indispensable if the subsoil is cold and ungenial to prevent the descent of the roots into a medium, in consequence of which the Vines would soon suffer in one way or the other. But besides the precaution of making an impenetrable bottom, a drain should run parallel with the extreme front of the concreted site and about a foot below its level, and communicating with this main-drain there should be cross ones up to the very back of the viney if the border extends inside the house. These cross drains may be laid at 5 or 6 feet apart. Then broken bricks or stones should be laid all over the concrete and drains to the depth of, say, 9 inches, finishing off with a stratum of finer material, such as coarse gravel with the sand sifted out of it, so that the soil can never be mixed up with the rubble in the bottom; and if over all a thin turf with the grassy side downwards be laid, so much the better. With these cross drains and open stonework, and a good outlet to the main drain in front, there will never be any fear of stagnant water, against which the simply concreting and sloping the border would not be sufficient precaution.

There is a decided objection to laying a border on a hard concreted surface without any intervening stratum of open material to quickly and thoroughly drain it from all the water which passes through it from the surface.

However turfy and excellent in all respects the soil may be when placed on an impervious surface, the portion of it which rests immediately on the concrete becomes soured and unhealthy in the course of time. When the fibry organic matter has decayed, and the border is reduced to a more solid condition, the water which passes through it to the bottom can never drain away from the latter sufficiently not to be mischievous, even if the slope or fall is much more than that which has been named. In consequence of this the bottom stratum of the border, into which a great portion of the roots will find their way, becomes a soured paste, in which all the young roots will as surely perish as if they were cut off altogether; and by such an accumulation of water the temperature of the border is kept low.

Sufficient, we trust, has been said on this point to warn our correspondent from placing his soil on a hard surface through which water cannot find its way with ease. The amount of draining material which has been recommended will have the additional beneficial result of raising the border more above the surrounding level, which, if the natural soil be cold and clayey, is a matter of considerable importance. It is a great mistake to dig out deep pits for borders, especially if the ground is naturally wet, and much better is it to keep the body of the border well up above the level; and where, from the construction of the viney, this cannot be done, no pains should be spared in completely cutting off from the border all the water which falls into the ground around it. A good way of doing this is to cut a deep drain all round the border and fill it up to the surface of the ground with open rubble such as brickbats or stones. Unless some such means as this be resorted to, the opener material of which Vine-borders are generally constructed acts as a drain to the ground which surrounds it, and, consequently, it becomes a receiving place for the water that falls around it.

If our correspondent has his border repaired and filled-in during the course of the winter, care should be taken in doing so never to move or interfere with the soil and other ingredients which are to be mixed with it while they are in a wet condition. The moving and mixing of soil, however open and free it may be, while in a wet condition is sure to make it sour and unhealthy; therefore, unless it can be done in a dry and comfortable condition, it is best to defer the operation till spring when there are more chances of dry weather. Of course, if the soil can be laid and mixed under cover of a shed, mixing it can be proceeded with at any time.

Although "A YOUNG GARDENER" does not ask for information as to the sort of material of which his border should consist, it may be well to make a few remarks on this point.

What we consider to be most in harmony with the constitution of the Vine is an open, fibry, calcareous loam taken from a park or common which has not been under cultivation for a length of time, the older and fresher the better. It should be taken about 5 or 6 inches in depth, including the turf or grass which grows on it.

This should be chopped up with the spade and about a cart-load of old mortar rubbish added to every eight loads of loam, and to this about 4 cwt. of inch unboiled bones, and a load of thoroughly well-rotted hotbed or horse manure, and it will form what may be termed a first-rate border. Should the loam be more inclined to clay than sand, the amount of lime rubbish should be increased in proportion as the soil is heavy. We have in such a case used charcoal dust, and have also charred a portion of the soil in order to counteract the tendency that clayey loams have to become consolidated, no matter how turfy they are when used.

The number of varieties of Grapes which "A YOUNG GARDENER" proposes to plant in a house only 30 feet long is six. This is certainly quite variety enough, and unless some special object were in view, it would be advisable to have fewer sorts. We should prefer at the most three or four varieties of standard reputation. This is more particularly desirable from the fact that the viney having an east exposure and not a southern one, and also from the fact that the viney is to be used for keeping bedding plants for a good many months in the year. Under such circumstances it could scarcely be hoped that Muscats would be ripened, because with all the advantages of a southern aspect, and a high temperature, this fine Grape is in some seasons difficult to ripen. One of the very best sorts is, therefore, excluded. We will, however, name six sorts, as such is desired.

Black Hamburgh, Royal Muscadine, Snow's Muscat Hamburgh, Lady Downes', Raisin de Calabre, and Black Prince. Making a selection of four sorts, we would plant one Royal Muscadine, two Black Hamburghs, two Muscat Hamburghs, and one Lady Downes'.

It is now proved beyond all doubt that Snow's Muscat Hamburgh is one of the finest Grapes ever introduced; and, therefore, even for so limited a collection, two Vines of it are recommended. It is, however, when grafted on the Black Hamburgh that it comes up to its highest pitch; and so treated it can be grown into bunches little short of the Barbarossa in size, even in berry, and under any circumstance its flavour is second to no Grape grown. It has also the great recommendation of ripening perfectly along with such sorts as Black Hamburgh and Lady Downes'; and, therefore, we in this case recommend it in preference to the Muscat of Alexandria in any of its forms for an east aspect; and for a mixed assortment Hamburghs should be planted for stocks to it, and after the stocks have commenced to grow, the Muscat Hamburghs should be inarched on to them, green wood to green, and they will take in a few days comparatively.

As the viney is to be used for bedding plants, it may be an advantage to delay the planting of the Vines till May instead of March. By so doing, more particularly if they are to be planted inside the house, it may be more freely used for the object of doing the best possible for the plants next spring without being required to study the Vines. Independent of this consideration, we esteem May the best season for planting young Vines. The soil is then higher in temperature and less artificial heat is required, and from the natural impulse of the plants they will make a much stronger and more desirable character of growth than if planted early and stimulated with more artificial heat. Vines are frequently planted much earlier than the time here recommended; but there are special objects in view—such, for instance, as the bringing round of Vines into an early-forcing condition, which it is inferred is not what is intended in the present case. To plant early and allow the roots to remain inactive in a cold wet soil outside, allowing the Vines to come away without much fire heat till they have made a few leaves, is also frequently practised; but there is nothing gained by such a practice, and the Vines will break more strongly in their pots in a cool house, or pit, through the course of the spring, and will be ready to plant by the time the viney can be emptied of the bedding plants, about the middle of May.

D. THOMSON.

RUSSELLIA JUNCEA.—I read with interest your treatment of *Russelia juncea*. It was one of the prettiest plants I saw in Mexico. It may be important to its cultivators to know that the plant succeeds best when grown something like an alpine plant. The best specimen I ever saw was on a river bank, the roots being washed bare by the rains. To

look at it there you would think it was impossible that it could obtain any nourishment from the rock and old dead wood that was around it.—E. B. SPENCE, *Nurseryman, Darlington.*

THE AURICULA.

It is sometimes an easier matter to answer the questions of correspondents by simply writing down one's thoughts than to refer them to past numbers and volumes, where the information they desire may be obtained; and hence, as letters both as regards the culture, and names, and descriptions of this pet flower of mine have lately reached me, and as experience somewhat modifies one's own cultivation, I have thought it better to write this short paper than to refer my correspondents to past notices on the subject; and as many things combine to lead me to suppose that it will be a very popular flower, the observations which I am about to make may be of use to others than those from whom I have heard.

As to growth, then. A friend rather pointedly said the other day, "One doesn't grow Auriculas, they grow themselves;" meaning that you cannot drive them as you do some flowers, or even coax them as you may do some others. They grow well, look well, and then all at once they turn their head on one side—a fatal sign. You examine them: there is a species of black rot at the base of the crown "between wind and water," and away goes the plant. Or you have a sort you would like very much to increase. There is no taking off the top shoots, putting them into heat, or any of those nice contrivances whereby *Verbenas* and the like are multiplied by the thousand. No: you must wait their time. "I have at last had an offset of my wonderful white-edge," writes one of the best growers in the kingdom. One offset! and that a matter of congratulation! Hence, if Auricula-growing has its delights it also has its drawbacks; and one must make up his mind for some of those mishaps which occur in the best regulated families (of Auriculas). After a fair experiment on the subject I have finally determined not to grow them in any larger pots than those which are ordinarily termed 32's. This is contrary, I am aware, to the experience of Dr. Plant; but then we do not expect to grow them as he does, and we cannot afford to lose them as he can with his immense stock of plants. You may probably sometimes obtain finer blooms, but there is a great risk of soddening the soil and rotting the roots by overpotting. In the matter of compost I have also been led to believe that the better plan is to give it tolerably rich both when potting and top-dressing, and thus save the administration of liquid manure save in a very diluted form. An over-stimulation of the plants is, I believe, likely to detract from the quality of the flower and the healthiness of the plant, and is, I am sure, a frequent cause of the black rot.

Some years ago I warmly disputed with a friend, whose well-known signature *Phi* used always to gladden Auricula-growers, as to the advisability of shaking off the whole of the soil at the time of repotting, I believing in the old orthodox plan of so doing, he, on the other hand, advocating that a good portion should be left on. I believe his practice, the same as that of Mr. Lighthody, to be the correct one; and I have this year repotted my whole collection in that way. You do not thus keep the same soil from year to year on them; because, as you take away all around the crown of the plant at the time of top-dressing, that which remains when you repot will be replaced the following spring by a fresh supply of the same material. In another point, too, I shall alter my method of growth; but that is more owing to the early period at which the flower shows are held than for any other reason—I mean the place for wintering. I have generally done this in a sheltered portion at the back of a wall facing the north. The consequence was that this spring I had very few of my plants in bloom by the 9th of April. Notwithstanding the exceedingly mild winter with which we were favoured, we are not so much earlier here as I supposed; and hence, although in principle I prefer the plan of not exposing them to much sun, I must this year adopt it, and winter them facing the south, removing them as they come into bloom into the northern aspect, where my blooming-stage is.

Thus, then, the method of growth will be as follows:—Let us suppose the plants are now in your possession; and if not, the sooner persons desirous of growing them do possess them the better. They may now be kept in a frame, to which abundance of air is admitted, in some sheltered place facing the north, throwing the lights up on every favourable occasion, but closing them at night, and taking great care that not a drop of rain reaches the plants. Water carefully and frequently, according to the state of the weather, with either rain water or water that has been exposed to the action of the atmosphere. The Auricula is a particular flower, resenting ill treatment, and therefore in these little matters requiring care and thoughtfulness. Early in October they should be removed into their winter quarters, which should be in frames facing to the south or south-west, and water should be more sparingly supplied; as the days become shorter, the sun has less power, and the nights are consequently colder. It is well between that time and Christmas to look over the whole collection occasionally, to remove dead leaves, to brush off any aphides that may be on the plants, and to stir the surface soil a little. During all favourable weather air should be freely given; and at night, no matter what the weather may be, they should be carefully covered up. Frigidum makes about the best covering: it is warm, very durable, and easily managed. The condition of the pots must determine the amount of watering. Some will dry much quicker than others, owing to the pots being fuller of roots, and consequently capable of absorbing more moisture; but in no case allow the soil to become soddened, which is most injurious to the well-being of the plant.

In the first week of February the time for top-dressing will have arrived; and on looking at your plants you will perhaps wonder how you are ever to obtain a bloom from them. Leaf after leaf has been plucked off, and the aspect of the plants has been gradually becoming worse; but if a good heart be there you may look hopefully on. For top-dressing I use simply well-rotted cow-manure two or three years old, and silver sand. Shake off as much of the surface soil as can be done without disturbing the roots: this will be about to the depth of 2 or 3 inches. Replace with the top-dressing, which should have been passed through a sieve, and then gently water with a syringe, taking as much care as possible not to wet the heart of the plants. They will soon begin—after a few waterings, which should be done carefully—to exhibit their sense of the change of diet and treatment. No convalescent from a hospital will do so more than they; and in a month the change is quite wonderful. The trusses will now begin to appear, and the plants may be removed to their blooming-quarters. Where it is practicable a blooming-stage should by all means be erected; and where there is a good collection there ought to be enough to have the blooming-stage well supplied with effective plants. It is well, where the trusses are over-large, to thin out the pips with a sharp-pointed pair of scissors. Not less than seven pips ought ever to be shown in my opinion, and as many more as will consist with the elegance of the truss.

As they go out of bloom, if you do not wish to save seed, pinch off the heads. Be careful about green fly, and leave them in a north aspect until the end of July or beginning of August, then repot. My compost consists of about one-third each of rotted cowdung, loam, and leaf mould, with some silver sand. I do not, as I have said, shake out all the earth, but examine carefully the root. If the tap root is too long I cut it, and rub the cut with charcoal powder. All offsets should be taken off, and if large put singly into pots; if small, round the edge of a pot, three or four as the case may be. Water with a syringe or fine rose, and then return them to their summer quarters to make their second growth. If they show symptoms of blooming pinch off the flower-stem carefully, water sparingly until the roots are beginning to start again, and then proceed as before. With this attention a stock may be kept in good health, saving those occasional mishaps which will occur, and much enjoyment be had in the culture of this exquisitely neat and peculiar flower.—D., Deal.

and one after another of the old suburban nurseries are compelled to retire before the genius of the hod and the trowel. I have just seen the announcement of another of these disheartening instances. The Homerton Nurseries (Mr. J. Fry) are to be disposed of unreservedly on the 30th inst., the ground being required for building purposes. A few score of fresh chimneys will, therefore, add their smoke to the difficulties, already more than enough, of floriculture in those parts. I am induced to call the attention of the readers of the Journal to this sale, from the opportunity seldom to be met with, of acquiring plants of unusual size, and of favourite kinds, in specimen Fuchsias, especially standards, large Azaleas, and Camellias, all for *bona fide* disposal. There is also a collection of seedling Fuchsias, never let out, some of them double and novel, well worthy the attention of connoisseurs in such matters.—W. D. PRIOR, Homerton.

HARDY AQUATICS.

(Continued from page 226.)

WITH regard to the plants that are to occupy the aquarium, it rests entirely with taste to say whether it shall be planted with those that have white or yellow flowers only, or with such as afford a variety of colour. It may be white with *Nymphaea alba*, or yellow with *Nuphar lutea*, or many colours by selecting from the list of aquatics to follow. In any way an aquarium cannot be other than an oddity as a centre, but by no means a despicable one; yet it should be planted in accordance with the laws of harmony and contrast. The white Water Lily is second to no aquatic for forming a good centre of white; but the plants in the beds around should have flowers of a different colour, so with yellow, and so on. If the basin be planted with one species only it is not necessary to form it into terraces; but it should be pretty nearly of a regular depth throughout, as much as circumstances will allow. Three feet is deep enough for either of the aforesaid Lilies, and 1 foot 6 inches quite shallow enough. Neither of them appear above water, but their leaves float on the surface, still having one of the florists' highest recommendations—"the flower is borne well up above the foliage." I certainly should plant but one species only, or, if many, such only as would attain their greatest beauty when the remainder of the design was arrayed in splendour.

But we have arranged for plants of different heights, and must find them. Well, here they are in flower-garden order: centre, *Nymphaea alba*, *Hydropeltis purpurea* around it on the first step—the flowers are of a reddish-purple colour—and *Nuphar pumila* at the outside or edge, which will be improved by having *Myosotis cespitosa* planted on the margin of the water all round. It is not necessary to adhere to this arrangement, for there is ample variety of habit and diversity of colour in aquatics, so that by having but one of a species a large number may be grown in a limited space. However, where anything like effect is desired, the basin had best be planted with *Nymphaeas* in collection, *Nuphars*, *Alismas*, &c., for it is difficult to get aquatics to grow as even in height and outline as bedding plants. As far as regards fish in small aquaria, a few gold fish are an embellishment, but fowls have no business in such a place.

A stone basin is a good substitute for a clay-puddled aquarium but by no means equal to it, for the plants derive nourishment from the clay which they can never do from stone; besides, the stone basin is much more expensive than a puddled one. The basin may be formed of cement, which may be done by firmly ramming the bottom after it has been dug to the required width and depth, and it cannot be rammed too hard, and then placing a layer of lime-riddlings on the bottom and ramming it as hard as the soil; on this is spread with a trowel a layer of mortar an inch thick, formed of equal parts lime and finely-sifted ashes—the dust that passes through the riddle. This is allowed to dry, and if it has been well-wrought and put on quickly it will not crack. On this again a coat of Roman cement is laid an inch thick, which is formed of cement one half, plaster of Paris a quarter, lime finely sifted a quarter, with sufficient water to make it of the consistency of mortar. Blood instead of the water will render the concrete harder. A cheaper way is to use equal parts of finely-powdered lime and calcined marl, or

SPECIMEN FUCHSIAS, AZALEAS, &c., AT THE HOMERTON NURSERY.—The building mania appears to be as destructive to floriculture in the neighbourhood of London as in Paris,

Portland cement, with a little sand added, either of which will set as hard as a stone, and be impervious to water; but they should be laid on quickly or they are apt to crack at the joinings. Soil 6 inches thick will be necessary at the bottom of stone or cemented basins for the aquatics to grow in.

Now all ponds or lakes are formed in the manner before named, the only difference being in the size. A lake is simply nothing more than a basin on an extensive scale; but I will pass over the improvement of streams, lakes, and irregular pools of water for the present, and confine myself to the culture of aquatics.

Probably there is nothing so simple in the whole range of ornamental flower-gardening as the cultivation of water-plants, there being but two main points to attend to, which are providing a portion of soil for the roots to grow in, and to plant or place them at such a depth below the surface of the water as their size and habit require. Their peculiar natural habits should also be imitated. Those with floating leaves, as *Nymphaeas*, *Nuphars*, and *Villarsias* grow naturally in the deepest parts, whilst such plants as *Caltha* grow on the margin or in shallow water. The smaller kinds require to be but just within the water; whilst some do best when planted on the edge, but still with the roots in close proximity to water, of which *Myosotis* affords examples. Some, nay, the greater part, of the taller-growing kinds require to be planted near the edge in shallow water, as, for instance, the upright-growing grasses and reeds. In planting it is better to distribute them in groups than as single plants at regular distances. Even groups should not be regularly distributed, but disposed with irregularity in threes, or a dozen together, according to the extent of the water. They will thus look all the better. It will not look better to have all the tall-growing in one part, and the small in another; but the contrary. The smaller kinds will look better where the bank is broken by shrubs; and the taller kinds may be made to serve to distinguish between the shrubs on land and the water-plants by placing them where the bank is unclothed. As a rule tall-growing kinds ought not to be planted where the bank is a dense mass of foliage, or the outline of the water will be destroyed; nor the smaller kinds where they cannot be seen and examined. Where, however, the bank projects and is clothed with trees or shrubs, advantage should be taken to plant a group of the taller kinds in as great a number and as much variety of foliage as may be consistent with the plants on land. The inlets should be planted with the lesser kinds, those that appear much above water being excluded, except one here and there to fix or attract the eye, or the smaller ones might remain unnoticed.

Plants with floating leaves as a rule ought to occupy the deepest parts of the water; and as they are much less numerous than those growing in shallow water, groups of one species where the water is extensive, or of one genus when it is small, should be planted in one place. Even then they should not occupy the whole of the midwater, but with a broad channel between and distant from group to group they would appear as verdant floating islands, which, when arrayed in their summer dress, with their gorgeous white and golden flowers peeping from the watery surface, will be highly picturesque. If the plants be artistically disposed a lake will have much of the appearance of an old-fashioned flower garden, the tall-growing aquatics in groups being the shrubs, the large species the single specimen shrubs, whilst the floating species will represent the gorgeous masses of one colour of beds; water taking the place of the lawn.

Where basins or small pools already exist that have no steps or terraces to accommodate plants that require to be placed at different depths, half-inch iron rods, with a loop at one end so as to hold a flower-pot, bent so as to be the required depth below the surface of the water, and fixed firmly in the bank, will do much towards giving a greater variety of plants, and if the iron be galvanized they will last a long time.

A goodly amount of soil, mud, silt, or being all we want for these plants, I have only to consider how it is to be given. For large pools it is best given at the bottom of the water, whilst for basins and small pools the plants had better be in pots, except such as have floating leaves, which must have

at least 6 inches of soil to grow in. *Nymphaeas* even may be grown in pots, but not so well as when planted out.

Stiff loam alone is suitable for all the floating species and tall-growing kinds; but the others require vegetable earth, peat, leaf mould or bog soil one-fourth, strong loam half, and coarse gravel one-fourth; 6 inches is not too much for the taller species to grow in, but 3 inches will do for the smaller kinds. In assigning the plants to their places in basins of water regard should be had to effect, unless collection be wished for, when, of course, effect is not the object aimed at; but the depth each species requires to be in the water must be borne in mind at the time of planting.

Aquatics are best planted in the spring, for then they have a good opportunity to establish themselves during summer. The best mode of planting is to fasten a ball of strong loam round their roots, and drop them gently into the water at the desired place. Should the loam be of a friable nature, a large or small stone in proportion to the size of the plant must be fastened to the root in addition to the soil, or the plant will rise owing to the soil falling in the water. Those that require to be planted on the margin can easily be placed in the mud with the hand.

Water-plants are propagated by division of the root and from seeds.

Division is simply parting an old root, or taking off the offsets. Such species as emit roots from the stem or have stems floating beneath the water may be increased by putting in cuttings of the stems. An excellent plan for striking aquatic cuttings and raising from seed is to have a shallow stone basin, any size, about a foot deep, with a hole to let off the water and a tap to fill it; the bottom to be covered with 3 inches thick of stones and about 3 inches of soil—i.e., peat and loam in equal parts laid on the stones—it is then filled with soft or rain water. In this trough cuttings of the creeping kinds are planted, and seeds of the floating species are dropped into it. In this they can remain until of sufficient size to plant in their final quarters, when the water can be let off, and a fresh planting take place. Cuttings are best put in in March, and seeds as soon as they are ripe.

For the kinds growing on the margin, or what are, properly speaking, marsh plants, the trough will require to be full of soil to within an inch or so of the brim, covering the surface with a thin layer of moss. Saturate with water, and keep the whole well saturated afterwards. Offsets can be planted in March, putting them with their roots just beneath the moss, and seeds may be sown on the surface immediately after they are ripe. The seeds will vegetate more freely when the moss becomes decayed.

When the plants are large enough to transplant they may be transferred to where they are to remain, moving them with a ball of earth adhering to the roots; for although placed in the water yet a ball of earth is of as much moment to them as in planting any other plant, success being more certain with a ball than without. For small basins the plants are handier in pots, especially the smaller kinds, potting them in the compost already mentioned like any other plant, and placing a stone on the surface of the mould to prevent the plant being displaced. The tender kinds are best in pots, for then they can readily be removed to shelter on the approach of severe weather. The following list contains most of the ornamental species, a great many bog plants being excluded, as they are mostly inconspicuous in their flowers, though ornamental in other respects.

NYMPHÆA (Water Lily).—The queen of hardy aquatics is *Nymphaea alba*, flowering from June to August, white, with cordate leaves floating on the surface; Britain; Rivers, &c. *N. canadensis*, from Canada; similar to, if not identical with, the foregoing. *N. reniformis*, flowering from June to September; from Carolina. *N. odorata* (Sweet-scented), flowering in July and August; North America. *N. minor* (Smaller), flowers white, in July; North America. *N. pygmaea* (Pigmy), has white flowers, produced from May to September; China. *N. nitida* (Shining Cup-flowered), from Siberia; white flowers, produced in July and August. All are perennials, increased by division of the root.

NUPHAR.—*N. lutea* inhabits pools and sluggish streams; a native plant; flowers yellow, appearing in June and July. *N. pumila* (Dwarf Yellow), flowers in July and August; found in the Scotch lakes. *N. advena* (Stranger), a North American species; has yellow flowers in July and August.

N. Kalmiana (Kalm's), from Canada; flowers yellow, in July and August. *N. sagittifolia* (Arrow-leaved), has yellow flowers, from June to September. All are floating perennials, closely allied to the *Nymphaeas*.

VILLARSIA.—*V. nymphaeoides* (Water-Lily-like), a highly ornamental floating aquatic, with heart-shaped leaves, has umbels of yellow flowers, produced in profusion in June and July; England; found in rivers. *V. cordata*, a North American species, with cordate floating leaves, having yellow flowers in June and July. *V. ovata*, from the Cape of Good Hope, with ovate floating leaves, has orange flowers from May to July. *V. lacunosa*, from North America; has white flowers in June and July. The last two are half-hardy perennials, requiring the protection of a greenhouse in winter. *V. reniformis* (Kidney-leaved), *V. sarmentosa*, and *V. parnassifolia* (Parnassia-leaved), are evergreen, half-hardy perennials, from the bogs of New Holland, with yellow flowers, which are produced in profusion in July and August. They grow 1 foot high, except *V. parnassifolia*, which attains 2 feet, and flowers from June to October. The last three require to be taken up on the approach of frost, and to be planted or plunged in pots on the margin of the water out-doors in June.

RICHARDIA.—*R. ethiopica* is a charming evergreen perennial, growing 3 feet high, with white flowers; from the Cape of Good Hope. Much grown by cottagers in their windows, and mostly grown in a greenhouse, but quite hardy if planted under water beyond the reach of frost. *R. albo-maculata*, highly ornamental foliage, suitable for water-basins from May to October. Requires greenhouse protection in winter.

CALLA.—*C. palustris* (Marsh), from North America, has cordate leaves, and inconspicuous though white flowers in July and August. A perennial growing half a foot high.

ALISMA (Water Plantain).—All are upright-growing perennials, producing flowers in open whorls, branching more or less. *A. plantago* (Plantain), has white flowers marked with purple, growing 1 to 2 feet high; Britain; in pools. *A. parviflora* (Small-flowered), growing a foot high, has white flowers in July and August. *A. trivialis* (Trivial), grows 1½ foot high, having white flowers in June and July. This with *A. parviflora* are from North America. *A. natans* is a floating Welsh plant, with white flowers in July and August; it grows 6 inches high. *A. repens* is also a Welsh plant, growing from 6 inches to a foot high, having white flowers tinged with rosy purple in July and August. *A. lanceolata*, found in British pools, grows 1½ foot high, with spear or lance-shaped leaves; it has white flowers shaded with purple in July and August. *A. ranunculoides*, another native species, grows about 6 inches high, having purple flowers in August; it inhabits turfy bogs, and is a pretty plant. *A. parnassifolia* is a pretty, half-hardy aquatic from Italy, having white flowers opening in July; it grows 6 inches high.—G. ABBEY.

(To be continued.)

SOME GARDENS WORTH SEEING NEAR WARRINGTON, LANCASHIRE.

I GIVE you the names of a few gardens in this neighbourhood, also the names of the gardeners:—

Name.	Proprietor.	Gardener.	Station.
Winwick Hall	Rev. F. G. Hopwood	Mr. Campbell	Newton Bridge
Appleton Hall	T. Lyon, Esq.	Mr. Jenkins	Warrington
Bank Hall	Col. Wilson Patten, M.P.	Mr. Green	Bank Quay
Thelwall Hall	J. Nicholson, Esq.	Mr. Brownell	Thelwall
Bold Hall	Unknown	Unknown	Warrington
Orford Hall	J. Lytton, Esq.	Mr. Reddish	Warrington
Bewsey Hall	Lord Lilford	Mr. Bishop	Warrington
New Hall	Sir Robert Gerard	Unknown	Newton Bridge
Haydock Grange	J. Evans, Esq.	Mr. Bailey	Newton Bridge
Kewton Hall	R. Dewhurst, Esq.	Unknown	Newton Bridge
Culcheth Hall	T. E. Whittington, Esq.	Unknown	Newton Bridge
Grapenhall	Heys T. Parr, Esq.	Unknown	Newton Bridge
Newton Priory	G. McCorquodale, Esq.	Unknown	Newton Bridge

I will collect the names of some other establishments and give you them shortly.—R. SMITH.

COCKCHAFTERS.—More than 12,000,000 cockchafters have been destroyed this year in the canton of Bale, in Switzerland. The amount paid by the authorities as premiums for their destruction has exceeded 1000*fr.*—(*The Building News.*)

CALCEOLARIA CUTTINGS.

A MONTH since I took a lot of cuttings three joints long, put them round seven-inch pots in some loam from rotted turves, with a good lot of sand added. The cuttings are all alive at present, but none rooted, although they look well. Where am I wrong? The pots are in a Cucumber-frame.—A. A.

[We do not think you are wrong at all, except in placing the pots in a Cucumber-frame, if there is any or much heat in it. A cold frame would have been better. Do not attempt to hurry them. Let them have their six weeks or ten weeks to root if they like, the longer the better, provided the cuttings keep fresh. Keep your eye on "Doings of the Week." Mr. Fish is quite satisfied if his cuttings strike by Christmas. Just keep them green and all is right.]

KENSINGTON PALACE GARDENS AND HYDE PARK.

KENSINGTON PALACE is an irregular brick edifice of no architectural pretensions, badly placed in relation to the surrounding gardens, being lower than the greater part of their surface. The front of the Palace is to the east, with wings stretching westward, and then north and south. On the south is the lawn with flower-beds. Being bounded on the north and west by the Palace, the beds furnish three sides of the square; but a broad walk runs along the eastern side of the square to the windows of the Palace, which is an anomaly in architecture, without a hall or front door. The broad walk on the east side is furnished with flower-beds at each side; altogether it is a most incongruous piece of flower garden. It will require a clever artist to reconcile that part of the garden with the architecture of the Palace and its two side ranges of buildings.

The gardens are three miles and a half in circumference, and contain a circular basin, near the Palace, with three straight avenues diverging to three different points eastward. Two main gravel walks, each half a mile long and 21 yards wide, intersect these beautiful pleasure grounds from north-west to south-east with a broad, circumferential walk, and other gravel walks of communication to different parts of these thickly-wooded and extensive landscape scenes. One of the broad walks is very improperly terminated in front of the boundary railing on the Kensington road. The trees in some parts of the grounds have been planted in masses of a sort, in other parts they are gathered into thick groves of mixed kinds, and intersected by long straight avenues from different points. During the reign of George II. Queen Caroline formed what is called the Serpentine river by uniting several ponds. This was the first bold attempt to deviate from the straight line, and to give that beautiful variety of outline now so generally admired in the windings of a river. We were rather disposed to find fault with the meagre manner in which the long walk on the south-east side of the garden is planted. It affords length and breadth for a splendid ribbon-border on each side; but when we reached Stanhope Gate and saw the long vistas of flowering-beds and borders parallel with Park Lane, we became more reconciled to the state of things in Kensington Gardens.

Proceeding from Stanhope Gate to the Marble Arch, the first bed, an oblong, is *Cerise Unique* Geranium, edged with *Lobelia speciosa* and variegated Mint alternately; the opposite bed, *Imperial Crimson* Nosegay Geranium, then *Purple King* Verbena, edged with *Cerastium tomentosum*. Second bed, three rows of *Christine* Geranium, then white Ivy-leaved Geranium, edged with *Cerastium*; the opposite bed *Boule de Feu* Geranium, then *Purple King* Verbena, edged with *Cerastium*. Third bed, *Trentham* Rose Geranium, then *Mangles' Variegated* Geranium, with an edging of *Cerastium*; the opposite bed, *Punch* Geranium, then *Purple King* Verbena, edged with *Cerastium*. Fourth bed, *Anthony Lamotte* Geranium, then *Bijou*, edged with *Cerastium*; the opposite, *Stella* Nosegay Geranium, then *Purple King* Verbena, edged with *Cerastium*. Fifth bed, *Imperial Crimson* Nosegay Geranium, then *Madame Vaucher* Geranium, edged with *Cerastium*; the opposite, *Prince of Orange* *Calceolaria*, then *Purple King* Verbena, edged with *Cerastium*. Sixth bed, *Anthony Lamotte* Geranium, edged with *Bijou*

Geranium, edged with Cerastium: opposite bed, Calceolaria Anrea floribunda, then Purple King Verbena, edged with Cerastium. Seventh bed, Imperial Crimson Geranium, then Madame Vaucher Geranium, edged with Cerastium: opposite, Imperial Crimson Geranium, then Purple King Verbena, edged with Cerastium. Eighth bed, Trentham Rose Geranium, then Bijou Geranium, edged with Cerastium: opposite, Général Pélissier Geranium, then Purple King Verbena, edged with Cerastium. Ninth bed, Christine Geranium, then white Ivy-leaved Geranium, edged with Cerastium: opposite, Cerise Unique Geranium, then Purple King Verbena, edged with Cerastium. Tenth bed, Cerise Unique Geranium, then Purple King Verbena, edged with Cerastium and variegated Mint alternately: opposite, Imperial Crimson Geranium, then Purple King Verbena, edged with Cerastium.

The next scene is a border at each side, with a Holly hedge in the centre: the north side backed by shrubs. The back row at each side is Perilla nankinensis, then Calceolaria rugosa, then two rows of Punch Geranium, then Purple King Verbena, edged with variegated Mint. The next is a row of double white Feverfew at back, then two rows of Punch Geranium, then a row of Heliotrope Miss Nightingale, edged with Scarlet Nasturtium.

The centre of the next compartment is planted with Dahlias, with Aucuba japonica in front at one side, and on the other side backed by shrubs: the back row at each side is Purple Orach, which is now faded, then two rows of Ageratum mexicanum, then two rows of Lord Raglan Verbena, edged with dark-flowered Nasturtium.

The fourth compartment is furnished with Perilla nankinensis at back, then two rows of Bijou Geranium, then two rows of Verbenas Ariosto and Mrs. Holford, edged with a broad band of Gazania splendens in full bloom.

The fifth compartment is backed by a row of Perilla, then two rows of Prince of Orange Calceolaria, then two rows of Stella Nosegay Geranium, edged with two rows of Lobelia speciosa and variegated Mint, plant for plant alternately, and a very dressy appearance the edging has.

On the west side of the compartment facing the Park is a magnificent ribbon-border 400 yards long by 5 yards wide. At the back is a row of Privet, then a row of Dahlias overtopping a row of handsome Aucuba japonica, then a row of Perilla nankinensis, then a row of yellow Calceolaria rugosa, then two splendid rows of Punch Geranium, then Purple King Verbena, edged with variegated Mint.

Having passed the Park Lodge the next scene which presents itself is a strip of pleasure ground extending to the Marble Arch. The first bed is a circle planted with Coleus Verschaffelti, which looks shabby in comparison with the plants at Battersea Park. Another circle is planted with Verbena Lady Palmerston, edged with Cerastium; then an oblong bed of Minnie Geranium, edged with Lobelia speciosa; then a circle bed of Trentham Rose Geranium; then an oblong filled with Cannas and Ricinus communis (Castor-oil-plant or Palma Christi), conspicuous for their fine foliage; and an oblong bed of Prince Albert Petunia, edged with Cerastium. In the next department are two circular beds of Tropæolum elegans: an oblong bed of Punch Geranium, edged with Bijou Geranium; and the opposite bed, Punch Geranium, edged with Heliotrope Miss Nightingale; then two circles of Lord Raglan Verbena, edged with Cerastium, and two oblong beds of Canna indica. In the next scene are two circles of Lord Raglan Verbena, edged with Cerastium; an oblong of Punch Geranium, edged with Heliotrope Miss Nightingale; and the opposite, Punch Geranium, edged with Bijou Geranium; then two circles of Tropæolum elegans. In the last department are six circles furnished with Nasturtiums, which were dignified with the names of Tropæolum Pet. T. Eyebright, and T. Aurora at the Royal Horticultural Show on the 9th inst. The leaves may be useful in salads as a substitute for Cress, but to approach anything like an ornamental effect frequent attention must be given to the removal of the leaves. The four circles planted with Heliotrope Miss Nightingale are in full feather.

A bed of Wigandia caracasana is conspicuous beside the ride near Hyde Park Corner. In the height of the London season portions of the Park bounding the ride are furnished with chairs. It is amusing to see the movements of our country cousins: they sit themselves leisurely down on the

chairs until they see a gentleman at a short distance stretching out his leg and thrusting his hand into his breeches-pocket, who deposits something in the hand of the young man standing before him. The hint is sufficient, the seats are silently vacated, and it is then that the following notices, nailed to the young trees in the immediate neighbourhood, are visible. "The charge for the hire of chairs is not to exceed 2d. for each arm-chair, and 1d. for each common chair. The collector on receiving payment for the hire of a chair to deliver a ticket, which will be available for the day on which it is issued for any chair of the same description. The charge for season tickets is not to exceed 7s. for an arm-chair and 5s. for a common chair. Office, H.M. Works," &c.

WILLIAM KEANE.

HOT-WATER TANKS.

I THINK if "A COUNTRY CURATE" would procure a slate tank he would find it the most serviceable kind he could have, and the cheapest in the end. I have worn out two wooden tanks, and am convinced if I had only had one of slate in the first instance I should not have needed another at all. The slate is about an inch in thickness; the sides and ends are grooved into the bottom, and it is fastened together with screw-bolts and nuts. I make a loose wooden frame all round the inside, and a strip of wood on edge the height of the frame runs down the middle nearly to the end, so that the water can pass freely round. This is to support some slate of the ordinary thickness on which the plunging material (I use sand) is placed. The tank is then complete. A little strip of wood across the most convenient corner of the wooden frame is required to provide for the supply of water to the tank, and the opening can be closed with a small lid or plug. A slater who is accustomed to make baths would have all the materials ready to hand, and would make the tank either for so much per gallon, or, if the size were stated, he would charge so much for the material and the labour. There is not much difference in the cost of a small tank; but I think a large one would be cheapest if procured after the latter mode.—J. R. JESSOP.

GLADIOLUS DISEASE AND NAME.

A LIGHT soil does not confer immunity from disease, as Mr. Cattell, of Westerham, could tell "D." of Deal.

I imagine that Gladiolus is pronounced Gladee'ulus or Glad'y'ulus according to accent, and not to quantity. Nutricula is surely nutrit'ula. Putcoli is pute'oli. Does "D." wish the accent to fall on the last syllable "lus?"

The following rule is given in the preface to Edwards's "Latin Grammar":—"If the penult or last syllable but one be long, the accent is on it: but if the penult be short, the accent is on the antepenult, or last syllable." The antepenult is the third syllable from the end.—S. D. S.

LARGE SALE OF CHINESE AND JAPANESE PLANTS.—A large and important sale of plants from China and Japan is announced for sale by auction by Mr. J. C. Stevens, at his great rooms, 38, King Street, Covent Garden. They have been introduced to this country by the well-known traveller and author, Mr. Robert Fortune, and have been cultivated and propagated by Mr. Standish, in his nursery at Bagshot. Amongst those from China are the Abies Kamperi, or Golden Pine of the Chinese, a noble timber tree of great beauty; a fine evergreen Yew named Torreya grandis; a hardy Palm which may be seen growing in the open air in Kew Gardens, and finer still, we believe, in Her Majesty's garden at Osborne. There are also some strange-looking Pine trees brought from the country about Peking. Many of these plants have been discovered in districts far inland which are not visited by foreigners, and such plants are not likely to be again sent to Europe. The trees and shrubs from Japan are also of great interest. The curtain which has been drawn round the capital of that country for so many centuries was lifted for a brief space, and enabled us to see a high state of cultivation in so far as gardening is concerned. Here Mr. Fortune found nurseries on a very extensive scale, filled with new shrubs and trees of great

interest, both in an ornamental and useful point of view. Amongst those introduced to Europe we may instance the curious Umbrella Pine and various trees allied to the common Arbor Vita, but quite distinct from it. There are also a variegated Honeysuckle, some shrubs resembling our Holly, but in reality nearer to the Olive, new Chrysanthemums, and a host of other things. Curious enough, the Japanese seem to have had a taste for variegated plants long before that taste gained ground amongst ourselves. The Yedo gardens were found full of such plants. There was a variegated variety of Palm, of the Camellia, and even the Tea plant was met with in this condition. Many of these things have been exhibited at the horticultural exhibition, and are no doubt familiar to our readers. Mr. Fortune seems to have visited Japan at the right time, for now the gardens at Yedo which supplied all these interesting novelties are closed to foreigners, and are likely to be so for some time to come.

MUSCAT GRAPES.

I AM much obliged to Mr. Thomson for his answer to my letter. By the last sentence I see he is of my opinion—that the question is deserving of more attention than it has received; and by the kind manner in which you have noticed my communication, I am encouraged to send you what I know of the subject, hoping I may assist in eliciting something useful.

I have before me a French catalogue, in which the Vines are classed as *très précoce*, *précoce*, *ordinaire*, *tardif*, and *très tardif*, in which latter class I find the Muscat of Alexandria.

I asked this firm if I might place confidence in these qualifications, and was assured I might. "Then, how were they obtained?" "From the latitude of Paris, and from the open wall." "But this Muscat of Alexandria is marked *très gros*?" "That was from a hothouse." "Do you think these other Muscats and Chasselas marked *moyen*," when grown on the open wall, will improve in size if planted in a hothouse?" "No doubt some of them were capable of great amelioration, they had no information which of them." So for my amusement I bought some to try if they were capable of amelioration, but I never doubted their earliness.

I planted them in front of the permanent Vines in a house where there was bottom heat, and grew them a year before fruiting them. I found they were not much improved in size, at least, they were too small to be worth growing after I ascertained they were not more than two weeks earlier than the latest Vine in the house. In the front row I had Muscats Blanc Hâtif, Noir de Jura, de Meurthe, Ingram's, Trovère, Buckland Sweetwater, Chasselas Musque, Chasselas Blanc, Supérieur, Negrepoint, and Rose or Royal: for the permanent ones, Alexandria, Canon Hall, and Bowood Muscats. I have pulled them all out but Muscat Blanc Hâtif, that did not fruit, and is in front of a weak Vine which I intend to cut down again. I was sorry I could not try them another year, but the permanent ones required the room. If, then, with Vines, we choose the finest, and make them early, will doing so have the same effect on Peach trees? I trust there are among those who with so much ability supply the tables of the great with all that is out of season, that can either confirm Mr. Thomson and myself, or else explain where our error is.—G. H.

CONTRAST VERSUS SHADING—AMARANTHUS BICOLOR AND TRICOLOR.

WE agree with "AN AMATEUR" whilst criticising the bedding-out at the Crystal Palace this season, that contrast is the real giver of effect and not shading.

This latter certainly has its distinct merits, as also admirers—indeed it may be that the best-instructed eye would favour shading; that an artist who had made the harmony of colours—these in all their variations, even to the most neutral ones—his chief study, would find greater pleasure therein than when looking at the best and most tastefully laid-out gardens where contrast is the main feature in its arrangement. We admit, also, that it is far easier to give striking effect by the use of the most distinct colours

as applied by contrast than it is to attempt to cope with the numberless neutral colours within our reach by shading and the felicitous admixture of one colour with another of the same hue, yet differently tinted.

What gives us so great pleasure when one of Flora's most favoured band is placed before us, we need scarcely say is the evenly-balanced markings; we cannot err in our attempt to copy these types of real beauty from the hands of so unerring a master. Then let us not reject an attempt so seemingly legitimate, without a fair and well-studied attempt at its furtherance. As we have already intimated, the mode of shading as practised at some of our leading places, ill agrees with our ideas as regards the same; as with some of our most gorgeous flowers we would place the quietest neutral where it could the more readily give effect to the warmer colour. An instance we give below, which has an excellent effect.

Shades of scarlet, Verbenas planted, plant for plant—Fire Fly, Robinson's Defiance, Admiral Dundas, and Lord Raglan; or, again, Tropæolum Elegans, Ball of Fire, Garibaldi, and it may be Eclipse. In the same way with Geraniums, a good effect may be attained by planting alternately, Christine, and Variegated Flower of the Day, which may be edged with Fairy. Or to have an effective lilac bed with shadings, plant alternately Variegated Mint (*Mentha rotundifolia variegata*), and distinct pink, approaching crimson at the eye. These we might continue to a further length, but we have in view two plants which, as we have already suggested in these pages, should be brought more prominently forward in the variegated-foliage class, and which in their markings may read a lesson to any one upon both the subject of shading and harmony of colours. They are not by any means new, though little used. We allude to the *Amaranthus bicolor* and *tricolor*, which when well grown are exceedingly pretty. In their first stage of growth they are not unlike indistinctly-coloured *Amaranthus melancholicus ruber*. Like them also they have a great tendency to run straight up with but one stem. They look, perhaps, best so when not required more dwarfed in form.

When the plants have attained their growth, and previous to flowering, a number of very beautiful lateral leaves shoot out from the main stems all round, in form and size not unlike the bracts upon the Poinsettia. These are upon *bicolor* a light pleasing scarlet; those upon *tricolor* being a glowing variation of bright scarlet and yellow, not unlike in their markings the gayest Parrot Tulip. The larger leaves, which hang sufficiently away to admit of their being readily seen, enhance their appearance, by their dark colour, especially when in sunshine they are moved by a slight wind, peeping forth alternately from deep shade to sunshine.

An excellent effect may be attained by forming a centre (a tall upright one being chosen for the middle) in a well-planted bed of *Coleus Verschaffelti*, especially if a large one, and where the centre could be planted in size sufficient to give it as a central object distinct prominence. It is also of a height rather in requisition for a back row, where ribbon-bordering is done well, or for pots for summer and early winter decoration.

But, to return to the *Coleus Verschaffelti*. We have taken up and potted recently some fine plants, unsurpassed by any in colour, the same were planted out as mere cuttings previous to the frost of about the 20th of May last. We are fully aware that the success has been very variable, taking the country through, but we ask yet another trial based upon the experience gained by the past season.—WILLIAM EARLEY.

HARDY AQUATICS.

MENYANTHES *nymphæoides*, *Stratiotes aloides*, *Hydrocharis morsus-ranae*, *Sagittaria sagittifolia*, *Menyanthes trifoliata*, *Acorus calamus*, *Epilobium angustifolium*, *E. hirsutum*, *Lythrum salicaria*, *Eupatorium cannabinum*, *Osmunda regalis*, and *Valeriana officinalis*.

A combination of the *Typhas* and *Rumex hydrolapathum* (a handsome oriental-looking plant), with some of the minor-growing "borderers," is very effective. The *Osmunda*

* These as "borderers."

will grow fine if it can have peat or spongy soil, and is not planted actually in the water.

If it will avail "L. R." to know where any of the above are to be found in Cheshire, I shall be happy to tell him, but I do not know any nurseryman who keeps such plants. —K.

CULTIVATION OF HEATHS.

(Concluded from page 228.)

WATERING at the right time and in a proper manner I consider essential to the successful culture of heaths; but then if the plants are potted with the soil and in the manner I have described, there is less chance of giving them too much or too little. The soil absorbs a certain amount of water, the rest drains away, and what the soil retains will never stagnate, for a healthy plant will gradually appropriate it; and if by chance water should be withheld until the soil becomes dry, its free open nature will soon allow it to percolate through. A heath seldom requires water immediately after potting, and sometimes it may remain a week or two, supposing it to be in the winter, for I follow no rule as regards the time of the year in potting; but when a plant is watered for the first time after potting, it should be done thoroughly, so as to wet the mass of soil through, and this cannot very well be done without filling up the pot three or four times. This is invariably my practice, for I find that if the soil is not properly moistened at the first watering after potting, it never becomes so afterwards, and plants have often died in consequence. After this, when the plants want water, filling up once will be sufficient. A practised eye can tell at once when a plant wants water; but few good growers ever trust their eyes only, but generally ring the pot and feel the soil in addition. At the first watering after potting, I generally use a fine rose, but afterwards merely pour the water on the soil from the spout of the watering-pot. During the summer, and while in flower, heaths require a great deal of water; but in the winter, and while at rest, they may be allowed to become all but dust dry, for a heath may appear very dry, and even flag, when a watering will cause it to expand and pick up again; but when a plant shows signs of distress from over-watering, it is mostly in a dying state, and will be hard to recover, even if that be possible; but there is little fear of over-watering provided the soil is free and open, and the drainage perfect.

SUMMER TREATMENT.—About the beginning of May, the more hardy sorts, as *gracilis* and *Willmorei*, may be set entirely out of doors, if the soil is free, and the drainage good, and they are placed on a good bed of ashes, on boards, or bricks, or in any way so that worms cannot get into the pots, and they will take no hurt until about Michaelmas if they are merely watered as required. But for choicer sorts no place can be better than a brick-built pit, having a good slope or pitch to prevent the possibility of drip from the glass. Pull the lights entirely off on all favourable occasions, putting them on in wet weather, and on bright sunny days, and adding a slight shade, but tilt the lights at the side, and keep neither lights nor shades on longer than is necessary to protect from rain or too bright sunshine. They are sometimes stood in a shady place without covering. In this case they must be turned on their sides, should heavy rains occur; but if left too long in that position they are apt to turn the points of the shoots upwards, which puts them out of shape. In my younger days I have been called up in the middle of the night to turn down a lot of specimen heaths, and other plants. This is no joke; and although I would rather do it now than allow favourite plants to become injured or killed, still I would rather evade the necessity of doing so, or of giving others the trouble by putting the plants in a place where they would be safe from injury from drenching rains. In places where there are plenty of hands to run and shut up pits, frames, &c., or turn down plants, there is less chance of accident; but in most places this is not the case, and it becomes necessary to avoid such running about, which breaks into the day's work more than lookers-on would suppose. And if plants are to be kept under cover, it must be where they can have fresh air night and day, and not be overhung by other plants.

WINTER TREATMENT.—When housed about Michaelmas,

supposing the plants to have been freely exposed, care should be taken to give them all the fresh air that can be admitted to them, for under no circumstances will they thrive and do well in a close or confined atmosphere. Keep them cool, and rather dry than otherwise, and never attempt to hurry them into growth. I should have said that after about the middle of August, the more sun the plants have the better, as this will harden the wood, and induce them to flower better. In the autumn and winter mildew sometimes attacks the heath, but rarely have I had plants troubled with it, as good drainage, a free open soil, and plenty of exposure to the air, will prevent it, and if it has made its appearance a dusting of sulphur will cure it. Heaths are also sometimes infested with scale, but this is only when they become potbound, or are crowded too much in the wood, or are placed too closely together. This pest is difficult to eradicate if it happen to get ahead, but strong soapy water rubbed on with a sponge or soft brush will destroy the insects. Some of the softer-wooded kinds are sometimes troubled with green fly, which is easily destroyed by fumigation. But, generally speaking, heaths are very clean in their growth, and if kept in good condition will give the cultivator very little trouble as regards pests of any kind. This I consider a great recommendation to their cultivation.

THE TRAINING of heaths not only requires both skill and judgment, but it is an art acquired only by practice. A well-grown and well-trained heath is one of the most beautiful productions of the plant department that can well be conceived. To grow and train one as it should be requires no mean display of skilful handling. There should be few sticks, and those thin and tapering, and painted green to match the foliage. The bast matting should be good, and used very thin. I greatly dislike using thread, as some make a practice of doing. The shoots should be trained-in at regular distances, at the same time giving the whole plant a natural and easy appearance. But those who know how to train a heath will not want telling, and those who do not, will learn more by practice than from description. Men who have to use heavy tools can seldom train these plants well, and this is often exemplified in the specimens produced in many places, and which exhibit a countless host of sticks, and an appearance the opposite of easy or graceful. A heath to look well should have the pot proportioned to the size of the plant, and be trained in such a manner that the eye is not attracted by the sticks.

THE PROPAGATION of heaths is not generally a part of the duties of the gardener, very few gardeners can spare the time necessary, or have a suitable place in which to strike heaths. Propagators of heaths and other hardwooded plants must undergo a certain training in order to qualify them for the work, and when they become competent they generally command good wages. Propagating such plants is an art, and, according to the division of labour it should be left to those who have studied the art, and certainly those who are unacquainted with it must not suppose it is equivalent to striking cuttings of *Geraniums* and bedding-out plants. Some kinds of heaths will take from six to nine months from the time of putting in the cuttings till these become rooted, and some hardwooded plants will take twelve months, and all this time they require daily attention in wiping the glasses, shading, &c. I simply mention this, so that those who may be unacquainted with the process may be prepared for what they have to do should they make the attempt. I have struck various kinds of heaths more for amusement than anything else, and in five years' time have had plants which I consider repaid all the time and attention they required. "This is a long time to wait," many will say. True, but then the time comes at last, and it must be remembered that there are propagators now engaged in putting in cuttings of heaths that in three or four years' time will make small flowering plants. The process I have followed is to fill two or three pots of a suitable size about three parts full of drainage broken rather small, then a layer of peat fibre, then a mixture of peat and silver sand, then half an inch of well-washed silver sand, the whole well watered. The cuttings are small shoots about an inch long, taken as near the collar of the plant as possible and the lower leaves stripped off. They are dibbed into the sand with a very small dibber, and a little water is allowed to drip on them to settle the sand about them. A bell-glass is then

put over them, and they are set in a shady part of a warm greenhouse; no sun is allowed to shine on them, and the inside of the glass is wiped every day. F. CHITTY.

THE GRAPERIES OF MR. MEREDITH.

I AM far from finding fault with your intelligent correspondent "EPSILON" (see p. 209), for calling me to account for what I said about the Grape-houses of Mr. Meredith at Garston. All vague and undefined assertions ought to be called in question, and not accepted as valid until some feasible proof, or at least explanation of them, can be given. Certainly now and then a loose expression may be allowed to pass uncriticised if the meaning be understood; but as the quotation your correspondent makes from my former article may leave an impression that I may have said too much, I deem it right to explain the matter more fully, and think I can do so without withdrawing in the least from the statement I first made.

The remark quoted by "EPSILON" from my article on the Garston graperies is that "I believed Mr. Meredith's knowledge will enable him to pronounce whether a certain soil will suit the Grape Vine or not, apart from those outward appearances which are the only guide to a less practised hand." Now, on reading this short paragraph once, and calling to memory what I saw and heard as well from others as from Mr. Meredith himself, I do not think there is anything to retract. Perhaps if the two words "upon examination" had been added after the word "pronounce," the sentence might have been more explicit, but I do not see in which way it would have altered the sense, the more especially when the general reader is informed that the opinion I gave was not formed alone upon the Grape Vines I saw at Mr. Meredith's, but what I saw had been done by him at another place many miles distant from his own establishment. I was told other places formed by him presented like features of good Grape-growing. But I will content myself with describing what I actually saw, and the reader will excuse my mentioning names for reasons which it is needless to explain; but I may say that the Grape Vines in a garden of high repute falling into a bad condition, the Grapes not colouring well, otherwise shanking, while the bunches and berries were below second-class size, and yearly becoming worse, it became necessary to restore them, and Mr. Meredith was called in. What alterations he advised in the houses I need not enter upon, as that is a mere mechanical affair. The evil lay in the border, and its reconstruction was put into Mr. Meredith's hands, and I understand he had the privilege of selecting the soil best suited for the purpose that the estate, and that a large one, possessed.

Now, though my visit to the place was a short one, I could easily see by the character of the agricultural and other crops that there was plenty of what is usually called good land; some in the park might be pronounced excellent, from the vigour of the herbage and the appearance of the trees, and many parties with a *carte blanche*, as I believe Mr. Meredith had, would have been for skinning a large portion of the best of it; but no, Mr. Meredith went further a-field, and I believe the bulk, if not all, of the material he recommended the border to be composed of was brought from an unpromising waste.

I am not certain whether a mere glance at the various soils or a more careful examination of them enabled Mr. Meredith to select the one he did for the formation of the Vine-border, neither does it matter to the general reader. Certain it is that the one he did select, with the other treatment the Vines received, produced as good Grapes as I ever saw in my life, equalling those at Mr. Meredith's own place, and if anything heavier crops. My informant of what was done by Mr. Meredith was the gardener on the spot, a worthy and well-informed man; the Grapes I saw myself, and I never saw finer. The alteration in the border taking place some three or four years ago, I was told the crop of the present year, heavy as it was, was not more so than that of last year, the gardener naively saying that an unusually heavy crop seemed necessary to curb the luxuriance of the Vines. I must here again repeat what I before affirmed of Mr. Meredith's Vines—the leaves were not so large as I

have seen some elsewhere, nor the wood so long in the joints. I believe this to be owing to the absence of those enriching substances which so many are apt to put in such abundance into their borders.

Although it is quite excusable, nay, highly recommendable, for an inquirer like our worthy correspondent "EPSILON" to question Mr. Meredith's ability to give a just opinion at once of the merits of a soil suited to the wants of the Vine, with no further proof than was given at the paragraph quoted, I think the above case fully confirms all that was stated, and I know other examples could be cited. It matters little to the general public whether Mr. Meredith in giving his opinion on the merits of a soil does so at once or takes time to do it, the judgment eventually is a correct one, as the sequel proved. And as Mr. Meredith is professionally employed in the building and furnishing of Grape and other houses, it is only fair that those who want to have further particulars should communicate with him direct. Those who require further confirmation of what I have advanced might go and see for themselves.—J. ROBSON.

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.—SEPT. 22, 1863.

FLORAL COMMITTEE.—On this occasion special certificates were awarded to Messrs. Veitch, and to Messrs. Downie and Co.; to the former for the beautiful white-flowered *Lapageria rosea albiflora*, a plant the white bells of which contrast well with those of the better known rose-coloured kind, and which will unquestionably prove a most important acquisition for the decoration of our greenhouses and conservatories, as well as for exhibition purposes. What a brilliant effect a pair of *Lapagerias*, the one with rose-coloured the other with white flowers, would have in a mixed collection, especially if they were as large and handsome as the specimen which Mr. Uzzell exhibited at the Crystal Palace. In the same collection with the *Lapageria* were shown the new *Lilium auratum*, a fine variety of *speciosum rubrum*, and two *Eranthums*. Both of these received second-class certificates. That named *tuberculatum*, from New Caledonia, formed a compact bushy little plant and had a profusion of pure white flowers; the other, which was of taller growth, had white flowers dotted on the under segments with purple. Messrs. Downie's award was for a collection of thirty-six *Hollyhocks*, of which Neatness, a deep crimson, had a first-class certificate; and Lord Clifden, a crimson shaded with carmine, a second-class one. Among *Dahlias* Willie Austin, from Mr. Keynes, of Salisbury, a rich golden yellow shaded with red, had a first-class certificate; and Miss Herbert, a variety somewhat resembling the preceding in its colours, a second-class one. Mr. Legge, of Edmonton, had likewise first-class certificates for *Nonsuch* and *Enchantress*, the latter a yellowish-white, heavily tipped with cerise. *Fairy Queen*, a rosy-lilac on a creamy-yellow ground came from Mr. Alexander, of Leyton, and had a similar distinction conferred upon it. Mr. Turner, of Slough, had second-class certificates for *Favourite* and *Countess* (Fellows), the former a good purple, the latter a large white variety. *Erebus*, nearly black, was shown by Mr. Rawlings, and was commended.

Messrs. E. G. Henderson & Son sent *Anemone vitifolia* and *Honorine Jobert*, which was commended at the previous Meeting; also *Pelargonium Beauty*, for which a first-class certificate was awarded. This was one of the *Zonale* class, having white flowers, the base of the petals edged with salmon pink, and was altogether a very attractive kind. *Cheiranthus Marshalli variegatus* from the same firm was commended, and three semi-double varieties of *Dianthus* hybrids, white, crimson, and striped, had second-class certificates.

Mr. Gordon, of the Crystal Palace, sent several bedding *Lobelias*; and Mr. Wills, of Oulton Park, Tarporley, two *Pelargoniums*—*Princess of Wales*, a horseshoe with pink flowers, deep salmon at the centre; and *Volcano*, bright scarlet. The former received a second-class certificate, the latter a commendation.

FRUIT COMMITTEE.—Mr. Edmonds in the chair. Mr. Carr, gardener to P. L. Hinds, Esq., Byfleet Lodge, Cobham, sent a *Queen Pine* weighing 7 lbs. 3 ozs., which was

awarded a certificate of commendation as an example of meritorious gardening. A seedling Peach was sent by Mr. Rust, of Broom House, Fulham, called Thames Bank. It is a large yellow-fleshed Peach as large as Late Admirable, and with the broad broken stripes of that variety. It was found to be a good Peach and received a certificate of commendation. Fine dishes of Selway and Late Admirable Peaches were received from Mr. Thompson, gardener to Mrs. Dixon, Stanstead Park, Sussex, which were much admired for their handsome appearance, but the flavour of both was inferior. Mr. Veitch, of Chelsea, exhibited three varieties of Syrian Peaches, one of which had a bitter kernel. Neither of them was named, but they were distinguished by numbers. No. 1 was a good-sized oval Peach with a dark red cheek; the flesh tender but not remarkable for flavour. The kernel is bitter. No. 2 was also a good-sized fruit with a green skin like Barrington, and very dark red at the stone; but the flesh was coarse and the flavour inferior, while the stone was unusually large. No. 3 was of larger size than the others, but the flesh of this also was coarse and not remarkable for flavour.

Messrs. Downie, Laird, & Laing, of Sydenham, sent a bunch of a Grape which proved to be Black Morocco. Mr. Turner, of Slough, sent a dish of Belle de Fontenay Raspberries, which were of large size and very handsome, possessing a good deal of flavour considering the late period of the season, and they received a certificate of commendation. Mr. Rivers, of Sawbridgeworth, brought fruit of a Peach called Clemens Isaure, a large yellow-fleshed fruit deeply stained with red at the stone; but it was acid, and without much flavour. Coe's Large Yellow is also a yellow Peach, and it, too, had a cold acid flavour. Columbia, a dusty-coloured and very downy Peach, was remarkable as having the flesh deep red for some depth under the skin and thence quite pale to the stone; but it was very acid, and without flavour. A seedling Plum, raised from Coe's Late Red, was richly flavoured. It is yellow and oval like a Small Coe's Golden Drop, and promises to be an excellent variety. The Nectarine Peach, a seedling raised by Mr. Rivers, partakes of the character of the Peach and Nectarine both in shape and flavour. Round the stalk the fruit is quite smooth, and over the remaining surface it is covered with a fine down. The flesh is very tender, juicy, and richly flavoured.

THE GLADIOLUS QUESTION.

I HAVE been much interested in the Gladiolus controversy which has appeared in your pages of late, the result of which I trust will enable your subscribers and others not only to grow the bulb properly, but to know what to call it when they have grown it.

The proper pronunciation of the word "Gladiolus" has certainly been a matter of dispute for some time, and, as "D." of Deal, observes, is continually a subject for argument, and to this day is not settled. I do not see, however, why it should not be settled after the very satisfactory explanation given by the above writer in your Number for the 15th inst., which further agrees with the statement given by "R. T. E., *Shrewsbury*," who quotes Ainsworth, Riddle, and other lexicographers as authorities.

As regards adopting the gardeners' pronunciation of the word, I think that could scarcely be a rule to be relied upon, although we have many instances, no doubt, that if the strictly classical pronunciation of plants was adopted it would appear affected and pedantic; custom having given a pronunciation which in time becomes accepted as correct. If, however, Mr. Beaton has a better authority for his pronunciation of the word than the one above referred to, let us adopt it; if not, I think we cannot do better than settle the matter at once by bowing to Ainsworth and Riddle as set forth in your Number of the 1st inst.—R. TICHBORNE, *Southampton*.

HOYA IMPERIALIS.

"E. M." asks us "Which is the handsomest plant to cultivate and train in a trellised pot?" This is a wide question, and we can only reply that the plant so cultivated and trained which we have never seen surpassed was a

Hoya imperialis, and of that plant we here publish a portrait. It was exhibited by Messrs. Lucombe, Pince, & Co., of Exeter. This beautiful flowering climber was thus noticed by Dr. Lindley at the time of its first introduction in 1846:—

"Imagine a true *Hoya*, with woolly stems, leaves 6 inches long, and clusters of the most magnificent flowers, forming a diadem of ten rays; each flower fully 3 inches in diameter, and with the delicate texture of the common *Hoya carnosa*, and you will have some notion of this superb species. In Mr. Lowe's letter from Sarawak, dated January 12th, 1846, we have the following account of its discovery:—On the next day, when in the territory of the Gumbang Dyaks, I found another curious plant, belonging to *Asclepiads*; it is an epiphytal climber; there was but one individual, growing from the decayed part of a tree, also overhanging the river. The flowers are large and in umbels; the leaves are leathery; and the stem abounds in a white, perhaps acrid, juice. The contrast between the purple of the petals and the ivory white of the parts of fructification renders it highly beautiful."

It requires a strong rich soil to sustain fully its numerous large flower-trusses, which are produced throughout the lengths of its twining stem. At Kew they used a compost of equal parts loam, decayed leaves, and peat, with some flakes of dry, half-decayed dung intermixed, with sand and broken crocks mixed liberally throughout. Each flower lasts a long time without fading, and is highly fragrant throughout the evening and night.—(*Botanical Register—Botanical Magazine*.)

PLANTS IN BALCONY-BOXES.

LAST year I had plants in window-boxes, *Geraniums*, *Calceolarias*, &c., and with your assistance and advice succeeded pretty well. This year I had evergreens in pots in the balcony, and these shaded the window-stools so completely that nothing did well. The evergreens are, however, so pleasant that I am unwilling to give them up, and propose having next year boxes with small rockery and alpine plants. Will they do shaded? and if so, will you mention a few names of those which have flowers with decided colours, and when I ought to begin operations? The boxes might be

4 feet long by 2 feet wide. Is cocoa-nut fibre refuse useful for such plants?

Is it the case that *Kalmia latifolia* will not blow two successive years in pots? Mine have made their fresh wood, &c., very well.

Can plants of *Verbenas*, *Calceolarias*, &c., be kept in a room with a north aspect during winter? I have great difficulty in town. I have no garden where I can put out anything even to stand. There is such a rush of wind in a small yard that nothing can be left in it. House faces south, but there is no spare room in front.—A CONSTANT READER, *Dublin*.

[We fear that with the shade you will not do much good with alpinas, so as to secure anything like continuous bloom of distinct colours. For spring work you could have nothing better than distinct colours of double Primroses, Polyanthus, &c., and these would then be at home in your yard during the summer. For anything else in summer, a stout net stretched over the yard would greatly break the force of the wind, and keep away those torments of gardening, the cats. You might then have a fine display of Tulips and Hyacinths, bringing them on in the yard or a cold room, and then transferring them to the boxes. To keep them green all the year round with little trouble, you might plant them with succulents, such as the House Leek, *Sempervivum tectorum*, which would yield purplish flower-spikes in July; montanum, which is dwarfier and gives reddish flowers; globiferum; Hen-and-Chickens *Sempervivum*, yellowish flowers; and other kinds as arachnoideum and flagelliforme, all blooming about midsummer. These planted in sandy loam would scarcely require even watering unless when showing bloom, and in hot weather in summer. For a neat carpet of green nothing can excel the Stonecrop, *Sedum acre*, and its varieties; for in May, June, and part of July it is a carpet of yellow, and needs little attention except pruning off the decayed flower-stems, and giving a little fresh surfacing of sandy loam. There is also a variety of this with golden foliage, so that yellow would ever be present. *Sedum roseum* is a rich rose colour, generally in bloom from May to August, and there are twenty or thirty species equally low-growing and pretty that would require little attention. Then among the Saxifrages there is umbrosa or London Pride, beautiful in bloom and out of it; hypnoides or Cushion Saxifrage, always a beautiful green, and covered with white flowers in spring; and the pretty *Cerastium tomentosum* and *Biebersteini* would make pretty cheerful lines round the boxes, if they did not fill the latter themselves. If the boxes were 9 or 12 inches deep, we would plant *Cerastium* in one, fully 4 inches from the surface of the box, for it would be sure to grow high enough, and then you might gem the whole by placing out of sight small pots of flowering plants with only the heads seen over the *Cerastium*. As your *Calceolarias* and *Geraniums* did well when there was not the shade of the evergreens, would it not be well to grow some for their foliage alone—such as a box of *Bijou Geranium* edged with Golden Chain, and all flowers removed, or the dark small horseshoe of Baron Hugel round a box of Cloth of Gold, or Cloth of Gold or the Baron edged with *Cerastium*? With such shade as you speak of, the foliage would be finer in the summer than when fully exposed to the sun. Cocoa-nut fibre mixed with the soil will do well for such plants, and so will the commonest sandy loam from the roadside. If you value your evergreens in pots, or tubs, you will act prudently in defending them from severe frost in winter, so far as the roots are concerned. They will suffer more if exposed in pots than in wooden boxes.

The *Kalmia latifolia* will bloom year after year in pots if well treated—that is, receives no check, has plenty of water, and the suitable soil. Nevertheless, in forcing this plant many turn it out and give it a season's growth, and take it up again the second year. If your shoots are so poor, there is less chance of the plant blooming; but if well ripened and hardened it may do so.

Calceolarias, *Verbenas*, *Geraniums*, and all such plants for summer decoration may be kept well in a room with a north aspect all the winter, provided they have plenty of light, plenty of air, when the outside temperature is 40°, and the plants suffer neither from frost, too much wet, nor too much dryness. The *Calceolarias* will need the most

moisture. Such plants before being taken to the south balcony in the middle of May, should be hardened-off in the yard for a fortnight or three weeks previously, covering them with a piece of calico or anything of that sort at night and during stormy days. We have known cases in which plants kept in a north aspect all the winter did very badly when at once transferred to a south atmosphere outside; but they did well when they had a few weeks in the outside yard beforehand. If we can render further assistance we will do so, and, perhaps, some friends will also be disposed to help in the matter.—R. F.]

ENTOMOLOGICAL SOCIETY'S MEETING.

THE September Meeting of the Entomological Society was held on the 7th inst., the chair being occupied by Mr. F. Smith, the President.

The donations to the Library received since the last Meeting were numerous and valuable, comprising the publications of the Geological and Entomological Societies of Philadelphia, Boston, Bavaria, Dublin, the Smithsonian Institute of Washington, the Royal Society, Society of Arts, Messrs. Lacordaire, Candeza, Le Conte, Hagen, Moiwitz, &c.

The Secretary exhibited portion of a bin which had been filled with Chicory, which, together with the woodwork of the bin was enveloped in a closely-spun white-silken web, covering the wood with a fine polished surface. It was suggested that this web had been spun by *Tinea granella*.

Mr. S. Stevens exhibited a small collection of insects captured during the recent expedition across the interior of New Holland by Mr. F. Waterhouse. Amongst the many new species which it comprised was a very brilliant species of *Tetracha*, belonging to the family of Tiger Beetles.

Mr. F. Bond exhibited a number of very beautifully preserved caterpillars of different kinds of Butterflies and Moths prepared by Mr. Baker, of Cambridge; and Professor Westwood described the plan adopted in Germany for the preparation of such specimens, the skin of the caterpillars being inflated by a blow-pipe and enclosed in a glass tube over a spirit-lamp, the glass being defended by resting on a semi-tube of thin tinware. Minute caterpillars were also preserved entire by putting them into a bottle held over a spirit-lamp for a short time.

Mr. Sharp exhibited a rare species of *Coccinella*, *C. Cabilis*, taken at Ilerne Bay.

Mr. Waring exhibited specimens of two rare Moths, *Lithostega nivearia*, from Suffolk; and *Stirra sacra*, from Banstead Downs.

Mr. Stainton exhibited a large tabulated plan illustrating at a glance and in considerable detail, the various leading peculiarities in the transformations and habits of the British genera of *Tineidæ*.

A paper by Mr. Walker containing descriptions of a number of new species of Moths belonging to the families *Castniidæ*, *Agaristidæ*, *Hylanopidæ* was read; also, a descriptive catalogue of the family of the Stag Beetles, by Major F. Parry, containing descriptions of a great number of new species; the collection of the author far exceeding in the number of species of these insects that of any other entomologist.

WORK FOR THE WEEK.

KITCHEN GARDEN.

FRESH plantations of Cabbages and Lettuces should be frequently examined. Any that droop without an apparent cause should be examined at the roots, where, probably, a grub will be found, which if not destroyed will continue its ravages. *Broccoli*, earth-up the plantations, as they will now be growing rapidly. *Cauliflowers*, continue to prick out the young plants under hand-glasses and in frames. A few may be potted in small pots and placed in a frame where they can have abundance of air and light, and be protected from excessive wet. *Endive*, plant out this and Lettuces for spring use. If planted on the sloping sides of wide ridges they will stand better, damp being quite as destructive as frost. Take the precaution of securing a quantity of both in pits or frames. *Mushrooms*, keep out-door beds protected from heavy rains by a good covering of litter. Maintain a

regular degree of heat in beds in houses, and guard against aridity. *Potatoes*, continue to take up the crops as they attain maturity. Sort them before they are housed or pitted, as it will save much future trouble and waste. *Seakale*, remove the leaves from this and Rhubarb if you intend forcing very early, and keep a look-out for slugs and weeds. We would advise to have two separate receptacles for garden rubbish attached to every kitchen garden (and we allude to this matter at present, because the accumulation of weeds and decayed vegetable matter is considerable at this season of the year), one to receive the matter convertible by gradual decomposition into manure, the other to contain every substance that can conveniently be burnt. A good reserve of burnt earth and wood ashes should belong to every garden; the last substance may be substituted for manure of a stronger character in rich soils which it is desirable to relieve. *Spinach*, thin the winter crop, leaving the plants about 9 inches from each other. Keep it free from weeds.

FLOWER GARDEN.

A sufficient quantity of good turfy loam for next year's operations should now be procured, stacked-up, and thatched with straw, or fern, to throw off rain, likewise peat and sand—both valuable adjuncts in propagating. Soils which have been used in the forcing departments should be brought here and mixed up with decayed vegetable heaps. This forms an excellent and useful manure for flower-beds. Prepare compost for *Roses* by frequent turnings, at the same time adding rich materials. The trimmings of hedges and other refuse from the shrubberies made into a heap and charred, will form a valuable article for stiff clayey soils. The variegated and other scarcer varieties of *Geraniums* should not be risked too long in beds, they had better be taken up and potted as soon as the weather appears threatening for frost; after potting to be placed, if possible, in a gentle bottom heat in a pit or house where the atmosphere can be kept sufficiently dry to prevent the foliage being injured. By such treatment they will soon become established, when they may be stored away for the winter in a cool dry house where they will be out of the reach of frost. The present is the most eligible time in the whole year for alterations, and whether planting or general groundwork, they should, if possible, be carried forward with vigour as soon as possible. Such operations should not be allowed to press on the ordinary business of the garden; extra work requires extra labour, and if such is not supplied a corresponding amount of injury must occur in some other department, which is the frequent cause of disagreements. Earth-up *Dahlia*s well above the crown that a sudden frost may not destroy them. The spare beds, if any, should now be put in readiness for the reception of *Hyacinths* and *Tulips*. Crown *Imperials*, hardy *Lilies*, bulbous *Irises*, *Narcissi*, and other bulbs should now be planted in the borders. These have a pleasing and interesting effect in spring.

FRUIT GARDEN.

The principal operations in this department are the gathering-in of the fruit as it becomes in proper condition, making preparations for filling up blank spaces, and trenching new ground for orchards and fruit-plantations. Prepare for planting all kinds of fruit trees, by getting the ground in good order for the different kinds. On cold stiff soils it is advisable to plant on hillocks 1 foot or 18 inches higher than the surrounding surface. The trees will not grow so fast in consequence, and will require more attention in summer in the way of mulching, but they will form short-jointed, well-ripened, fruitful wood, which is the best preventive of canker, gum, &c., and will save the labour of resorting much to root-pruning. Continue to keep the runners removed from the *Strawberries*, and those that have been some time potted for forcing should now be placed in a comfortable situation to insure their not being too much soddened with wet. Strong pricked-out plants may still be potted with good success if placed on a kindly bottom heat. Use every possible means to get the wood of *Peach* and *Nectarine* trees well ripened. If the trees are too thick of young wood, every shoot that will not be wanted at nailing-time should be cut out so as to expose those left to all the light possible. Keep the fruit-room cool and airy, examine the fruit frequently, and pick out any that are found to be decaying.

GREENHOUSE AND CONSERVATORY.

No time should be lost in housing the plants which have been placed during the summer out of doors; but before placing them in their winter quarters every pot should be examined. If any of the plants are water-bound, or the soil in which they are growing is too heavy and wet, they must be turned out and the drainage examined, and if necessary made new. The drainage in winter is highly important. *Hyacinths* and other Dutch bulbs should be procured and potted without delay. Look carefully after the watering of large specimen hardwooded plants in pots, especially *Heaths*, which are soon injured by being over or under-watered. Let *Azaleas* be tied into form as soon as can be done in order to give them a neat appearance. Keep *Cinerarias* as cool and moist as is consistent with safety, and attend to repotting such as require it. *Primulas* must also be carefully attended to, in order to encourage them to make rapid growth, especially double varieties. Keep tree *Violets* clear of their great enemy, red spider, by a liberal use of the syringe.

PITS AND FRAMES.

Presuming that all the tender stock of plants is safely housed, and anxiety with regard to their safety in a great measure diminished, proceed with the arranging and removing into spare cold pits the stocks of *Pentstemons*, *Antirrhinums*, *Linums*, *Phloxes*, *Brompton*, *Intermediate*, and other Stocks, and all herbaceous plants in pots that require a little protection. The pots to be plunged in sand or coal ashes, which is not only a protection but saves much labour in watering during the spring months. When all the plants are arranged this department should undergo a thorough cleaning, all litter and rubbish to be removed. If the foot-paths between the ranges of pits be in bad trim, a layer of gravel or coal ashes will add much to the neatness of this department. Pot-off cuttings. Establish a good stock of *Verbenas* in pots, as duplicates of the choice sorts; harden-off cuttings for bedding out next season, that they may resist the gloom of the approaching winter. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

RAN the Dutch hoe through many growing crops, where the rains had brought up a mass of weeds fast approaching half an inch in height. An hour's sun would soon settle them. Most of these were the never-ceasing annuals, as *Chickweed* and *Groundsel*. Where they all come from is perfectly marvellous. No wonder that would-be philosophers speak of spontaneous generation. For years we have hardly ever seen a *Groundsel* in seed, and yet every piece of trenched-up ground yields its myriads upon myriads. *Cow Thistles*, and other *Thistles*, too, have made their appearance, brought to us, no doubt, by the wind, from the fields and hedgerows of slovenly farming. One day in August, we were pretty well covered with *Thistle-down*—a hedgerow next the highway, with a fine field of *Wheat* inside, was as crammed full of *Thistles*, sending their downy seeds streaming for miles, as if some great prize had been offered for the best specimens of *Thistle-culture*. The only redeeming points in the scene were some beautiful goldfinches, that no doubt were deeply grateful to the waywardens and the farmers for securing them such a bountiful supply of their favourite food. With increased premiums for the best products of gardening and farming skill, it would be no bad move to inflict a fine for all specimens of winged seeds allowed to reach maturity. Once scattered over the soil, generations to come will not see the last of them. Though we managed to lay hold of a rabbit or two, yet fearing for our plantation of young *Cabbages*, we run a single width of net all round the piece, supporting it on stakes, and we have not since been disturbed by their ravages in that direction. Examined the *Mushroom-spawn* bricks, not too wet nor too hot; put straw covers over the heap to keep the wet from them. On Tuesday afternoon had a hurricane of wind and hail; but it has been rather warmer since, and the barometer, very low, is slightly on the rise. Cleared a piece of *Cauliflower-stalks*, and put more plants in thickly. Put old lights over a nice piece of *Dwarf Kidney Beans* to encourage them. *Peas* are doing better than we expected. Well watered a row of dwarf

ones under glass, just coming strongly into bloom. Earthen-up second piece of bed in the Mushroom-house. Nipped-in Cucumbers. Pricked-out more Lettuce and Endive. Thinned Parsley. Cut over a good part to make it stubby before winter. Regulated herb-beds. Watered Globe Artichokes, the watering with sewage water has given us a fine yield of Scarlet Runners, though previously from the drought the flowers were dropping off without setting. Took up part of Carrots, stringed Onions, &c.

FRUIT GARDEN.

Was obliged to fill the late vinery with plants from a house, which, in connection with a Fig-house at one end, we are repairing and elevating, in order to make a fresh arrangement within. The house was so low that, though 11 feet wide, we could only have a platform on each side and a walk in the middle; but by raising the roof 18 or 20 inches we shall be able to walk all round and have a platform in the middle, as well as small ones at the sides. In raising the wall opportunity has been taken of leaving spaces there for ventilation back and front, so as to avoid all necessity for moving the sashes. The wall plate in front was previously about 1 foot above the ground outside, the house, originally a Pine-pit, being sunk inside; and it would have been better to have had the fresh-raised part of glass, but this would have entailed more expense for sills and sashes, and we think we shall have enough of light for what we want. The roof has a short hip, and the rafters and plate having been repaired the roof was tied together and raised in a piece. The walls are 9 inches, and the openings admit a wooden box without top or bottom, so as to give a clear opening of 13 inches by 9. In the middle of this space a board of the above size, just so much less as to move easily, is hung by two screws as pivots, and about 3½ inches from the top of the box, so that the weight of the wider portion below will always keep it shut, unless when kept open, which it can easily be from a quarter of an inch to the whole space, when, of course, the ventilator will stand horizontally in the opening, and neither inside nor outside will it ever appear beyond the face of the wall. We have long found that all sorts of hinging are a continual annoyance, from rusting, breaking, and all the rest of it. Another fact we have found out is that, provided air is given early or left on all night, there is no necessity for so much air being given during the day. We think, on the other hand, that it is economical policy to make the sun do the work, which used to be done to a great extent by the coal heap. Of course, there must be as much moderation in this as not to scorch or burn what is under glass. That, however, is chiefly done not so much by the mere heat as by a confined, close, moist atmosphere, and that is reduced to a minimum by the early air-giving. Gave more air and heat to the late vinery to suit the plants and to prevent the Grapes damping. What are left of the Figs in the Fig-house, will now do little more from being exposed, but those out of doors have come in well. Gathered fruit as it ripened when dry. Went over Apricots and Peaches out of doors, nipping off laterals and shortening a few strong shoots to hasten the thorough ripening of the wood. Cleared Strawberry-beds of runners and litter, and slightly forked the surface to let the rains pass and prevent the frosts entering.

Now is a good time to make arrangements for fresh planting fruit trees, and in stiff or clay soils it is a good plan to plant on raised mounds, even though it be necessary to mulch the surface in dry seasons, which if done in time will prevent the necessity of much watering. After a regular trenching, fresh soil would be desirable for the mounds, if it can be obtained, and these may be 18 inches above the common level. When the ground is not well drained, a cartload of rough stones might be placed under each tree, and in as loose a position as possible, the smallest at the top. This, however, will not make up for the presence of stagnant water amongst the stones, the result of deficient drainage. In light soils they cannot be packed or beaten too firmly round the roots of fruit trees.

Now, also, is a good time to cut the roots of trees becoming too luxuriant, or if young to take them up and replant them as soon as the fruit is gathered. With this proviso as to the fruit, if it is intended to lift Vines, the sooner it is done after this the better, as the ground is still warm, and if a few leaves keep green even for a short time, the roots will im-

mediately begin to work, and will keep on less or more all the winter, if cold and excessive wet is excluded. As we may also now expect heavy rains, the outside borders of early vineries should be protected from wet to keep them at rest, and those of late vineries to keep the roots moderately dry and warm. There are many modes of doing this, perhaps none better than wooden covers or shutters, as these keep all below them dry. However, we cannot all have such nice materials to work with. Many employers are quick enough in speaking of some extraordinary result, but they turn their heads when some of the means come to be referred to. We have just done something, as in former years, to prevent our borders being soaked. A little cowdung is spread thinly over them, and then a very thin layer of tar over the cowdung, some eighteenpence worth at a penny a-gallon covering a large border, and on that is thrown a lot of road drift or sawdust, so as to make a crust and keep down the odour of the tar. Now this is all very well as respects mere dryness, but then it does little to retain warmth, as even if we put litter on, if we cannot keep it dry, we do little in the way of securing warmth, except we rough-thatch or do something of that kind. Now, we have proved that a border rather dry, covered in the end of September with a foot of dry litter, and then covered with tarred wooden shutters, would be pretty well warm enough for moderately early forcing, without any artificial heat being given.

ORNAMENTAL DEPARTMENT.

It is now time to take all greenhouse plants under cover. Excessive wet and a very cold or frosty night, will spoil the blooming of Camellias and Azaleas for the following year. Tied-up large plants of Chrysanthemums, Salvias, &c. Thinned creepers and climbers in conservatory. Kept stove plants drier to ripen the wood. Placed Gloxinias, Achimenes, &c., done flowering in a dry place beneath the stage in a vinery to ripen their tubers; ditto with Gesneras past their best. Gave moisture and heat to those growing and flowering. Lessened water to large plants of good-foliaged Begonias to get them gradually in a state of rest, when they may be kept in a small space, in a low temperature, and be potted and grown on next spring for the conservatory. Looked after mildew and red spider on Violets. Smoked some Cinerarias that seemed to have a little fly. Potted Chinese Primulas into 40 and 32-sized pots, using fresh loam and a little leaf mould. Put in lots of cuttings, that will go under frames, of almost everything for beds, as we want them just to throw out their first rootlets about November, so as to be small all the winter. It is very well to talk of potting cuttings off. If we did so we should have no place for them all the winter. We like them better the smaller they are until January, and then we let a few of them grow larger. Will prepare a pit for Calceolarias by the end of the week, so as to begin with a few of the scarcest next week. We will select side pieces for cuttings from 2 to 2½ inches in length, leave about three joints altogether, cut across at the lowest, and insert in sandy fresh loam, with a quarter of an inch of sand on the surface, and the cuttings 1½ inch in the row, 1½ inch from row to row, and about 15 or 18 inches from the glass. These, put in in the end of October, we will not expect to be much rooted until January; and the latest put in, if they have not been frosted, we will expect to be the best. Skimmed a part of lawn with the scythe, in order that we might pull up plantains, &c., before sweeping and rolling. The dry summer did not give us the chance before of weeding lawns. Switched the sides of the walks to remove tiny heaps collected by the rains, and rolled them. Just looked over Dahlias, Phloxes, &c., which may be good for some time if the weather hold fine. One piece of Dahlias was so dried that the flowers are not worth looking at even now.—R. F.

COVENT GARDEN MARKET.—SEPT. 26.

The supply of fruit and vegetables continues ample; there is an increase of importations from abroad, and a fair average amount of business is done. The importation of Oranges is for the present suspended, and Lemons have fallen in price in consequence of a further supply having been received. Pines and Grapes are quite sufficient for the demand. In Pears Marie Louise, Louise Bonne of Jersey, and Williams' Bon Chrétien afford the principal supply. Brown Beurré and Gansel's Bergamot are also coming in very good. In Apples Ribston Pippin are the most in request at this season. Cobnuts are bringing from 55s. to 70s. per 100 lbs. Of Potatoes

the supply still continues very plentiful; disease, however, is making its appearance to a much more serious extent than was anticipated. Of other vegetables the supply is also ample; a few Peas are still to be had, and some Savoy are coming in, but as yet are not in request. Cut flowers for the most part consist of Orchids, Roses, Pelargoniums, Asters and Mignonette.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

SEEDLING TROPEOLUM (*W. F. S.*).—The varieties are numerous and beautiful, but it is quite possible to excel them. Whether your seedling does so we cannot tell, but may be clairvoyants.

NECTARINE FOR NORTH YORKSHIRE (*J. F. N.*).—The *Violette Hâtive* is the variety most likely to ripen against your south wall.

GLASS FOR A FERNERY (*T. L. T.*).—We consider 21 oz. glass painted on the outside quite equal to Hartley's Patent for the roof of a fernery, and it only costs about half the money. The glass must be quite dry when the paint is put on, and the coat very thin, if it cover that is enough. Whilst the paint is wet dash a painter's dust-brush perpendicularly on the painting, and that will give it the appearance of frosted glass. The only objection we have to painting glass is that it makes the house gloomy in winter. Ground glass we have not tried, and fear it would not prevent the sun's rays from scorching the plants. We have a house glazed with Hartley's patent rough plate glass a quarter of an inch in thickness, and though we cannot see through it, it does not render shading unnecessary; in fact, it has to be shaded with tiffany No. 3 from March to October, and we think the same would apply to ground glass. We have a painted larnery roof little the worse at the end of four summers, and we never had a scorched leaf nor a pale-coloured frond, though the house is gloomy in winter.

CAMELLIA LEAVES SCORCHED (*S. W. C.*).—The Camellia leaves are scorched by the sun shining powerfully upon them whilst wet. The leaves of the Camellia should always be dry when the sun shines powerfully on them. The cellular tissue of the leaves of No. 1 appears to us to have become decomposed by keeping them almost constantly dripping-wet. Syringing is very little after the leaves attain their full size in future, and shade them from very bright sun, or plant some creepers that will afford a little shade in summer and obstruct the light but little in winter. No. 2 is spotted by allowing water to drip from the roof upon the leaves, or drops of water standing on them when the sun shines hereby will produce the same result. The glass of the roof may be of a bad quality, and that would account for the leaves being in the pitiable condition of No. 1; but No. 2 we are quite certain is spotted by allowing water in drops to stand on the leaves. There is no disease that we can see but what will be easily removed by keeping the leaves dry in the early part of the day, and syringing only in the evening; and then only when the plants are making new growths. A syringing once a week after the growth is made and buds formed is enough to free the leaves of dust, and a thorough washing with a sponge of both sides of the leaves is better than all the syringings put together. See that the soil about their roots is not sodden, and that stagnant water is not lodging there, and admit abundance of fresh air.

SHALLOT CULTURE (*S. W. C.*).—The Shallot likes a rich friable loamy soil, and if not rich it should be well manured previously to planting, and well rotted and incorporated with the soil before planting time. Plant in beds 4 feet wide, and draw drills with a hoe about 3 inches deep, and 9 inches from drill to drill, in which place the roots 6 inches apart, and fill in the drills with fine mould level with the surface of the bed. The beginning of February is the proper time to plant them, and if the ground be frozen at that time, plant as soon afterwards as circumstances will allow. Remove all weeds, and when the tops of the shallots turn yellow pull up the roots and let them lie on the surface a few days to dry, when they are to be housed like Onions.

PLANTS FOR ROCKERY (*F. W.*).—Creepers or otherwise small shrubs and herbaceous plants for rockeries—Berberis buxifolia, and B. empetrifolia; Genista decumbens, G. procumbens, G. tetragona, G. tinctoria, and G. tinctoria plena; Cistus purpureus, C. crispus, C. salvifolius, C. Ledon, and C. lusitanicus; Cotoneaster microphylla, and C. rotundifolia; Genista triquetra; Daphne cneorum, and D. cneorum variegata; Ulex europæa, U. europæa plena, and U. nana; Helianthemum vulgare, H. vulgare flore pleno, plenum album, H. roseum, H. macranthum, H. algarvense, and H. alpestre; Gaultheria procumbens; Kalnia glauca, K. angustifolia, K. angustifolia variegata, rubra, nana, and ovata; Juniperus prostrata; Ledum buxifolium, L. latifolium; Vinca minor, V. minor argenteo-variegata, aureo variegata, flore pleno, and V. berbaea; Vaccinium buxifolium, V. vitis-idaea, and the variety major; Yucca filamentosa, and variegata, Y. angustifolia, Y. recurva, and Y. gloriosa. Hardy Heaths—over thirty species or varieties, and the sweetest of trailing plants Epigaea repens. The small-leaved ivy, and, in fact, most of Ilexes are picturesque in rock-work. Of herbaceous plants—Achemilla alpina, montana, coenocarpa, hybrida, &c.; Ajuga reptans variegata, and A. reptans alba; Alyssum alpinum variegatum, and A. maritimum variegatum; Antennaria hyperborea, A. triphervis, and A. margaritacea; Arabis alba, bellidifolia, cerulea, saxatilis, variegata and stenopetala; Arctostaphylos alpina; Aretotis breviscapa; Aristolochia clematidis; Armeria maritima, ditto formosa and rosea, A. vulgaris alba; Artemisia maritima; Aster alpinus; Aubrietia Mooreana, purpurea, and its variety grandiflora; Campanula garganica and pulla; Cephalaria alpina and tatarica; Cerastium repens and tomentosum; Chelidonium majus, and the double variety thereof; Circea alpina; Coelestia danica, grœnlandica, and officinalis; Convolvulus fruticosus; Cornelia nidima; Dianthus alpinus, deltoideus, floribundus, hybridus; Dryas Drummondii and octopetala; Fragaria monophylla; Heuchera suffruticosa; Iberis carnea and sempervirens; Lotus corniculatus, ditto flore pleno and L. cytisioides; Phlox Nelsoni and rosea; Saxifraga, over a hundred varieties, and more than sixty Sedums, all charming for rockeries; and not less so are the sempervivums, of which there are more than a dozen species; and very many more plants suitable for rocks may be had at any nursery or note.

ROSES FOR BORDER (*Idem*).—Cabbage or Provence—Madame Laffay, Baronne Prevost, Duchess of Sutherland, La Reine, William Jesse, and Giant des Batailles, and one and all of the Hybrid Perpetuals are excellent border Roses on their own roots. They require no more care, and are every way better than a lot of old-fashioned Roses formerly grown in gardens which were infinitely inferior to a Dog Rose.

VINE CULTURE (*W. R. J.*).—To give all the information you require would fill an entire Number of our Journal. You must purchase a work on Vine culture. That by Sanders or by Thomson will suit you. As you do not require Grapes early you need not begin forcing before December. The air required to be kept moist by watering the paths, syringing the branches, &c. The borders, if properly made, require no manure. As the roots of the Vines are outside, the surface should be mulched in winter to exclude frost and excessive wet, and in dry weather during summer to keep in the moisture. The flavour of any variety of Grape depends on its good culture and the amount of sunshine.

LIST OF FRUIT TREES (*W. M. C.*).—Dessert Apples.—Irish Peach, Kerry Pippin, Cox's Orange Pippin, Bedford Pippin, Old Nonpareil, Margil, Kitchen Apples.—Kew-Apple Codlin, Cockleshire Foundling, Dumelow's Seedling, Yorkshire Greening, Striped Boeving, Alfriston. Pears.—Jargonelle, Williams' Bon Crêten, Baronne de Mello, Nouveau Poiteau, Winter Nellis, Josephine de Malines. Plums.—July Green Gage, Deniston's Superb, Jefferson, Green Gage, Purple Gage, Reine Claude de Bayay, Kirke's. Cherries.—Black Tartarian, May Duke, Elton, Bigarreau, Morello, Belle Magnifique.

BOX EDGING (*W. R. J.*).—Your gardener is quite right about there being more kinds of Box edging than one, as is exemplified in our own garden, where the difference of the two kinds may be traced to a plant. In fact, there are different grades of dwarf Box, the very dwarfest and best being far from common, while a coarse-growing kind, better adapted for hedges than edgings, has found its way into some gardens, our own for one. The dwarfing of Box edging does not depend on soil but on the kind of plant used, as we have detected three kinds in one line with clearly marked differences. Box is the Buxus sempervirens of botanists, and they have two varieties of it, angustifolia (narrow-leaved) and suffruticosa (sub-shrubby), and it is the last-named that is alone suited for edgings.

CHASSERAS MUSQUE GRAPES CRACKING, &c. (*Hibernicus*).—You will have little chance with the Chasseras Musque unless you can keep the house drier and prevent the roots being much soaked by placing a sash over the borders. We think root-pruning will do the Grosse Mignonne good, and thinning the fruit pretty well before they become so large. The Fuchsias may be so grown in a cool stove, with a fair amount of air. If kept too hot they will be apt to be leggy and too luxuriant. Your Fern is Notholaena nivea, sometimes referred to Gymnogramma.

SIZE OF CONNECTING PIPE (*Tyro*).—The one-inch will do for connecting the four-inch pipes with the boiler—we presume that is what you mean. It is amazing the rapidity with which four-inch pipes can be so heated. Of course, you are satisfied your boiler is large enough for the additional work.

DWARF TREES IN FRONT OF WALL TREES (*R. H. A.*).—If your trees are not more than 4 feet in height they will injure the trees on the back wall but little. It would be as well if the roots of the two sets of trees were prevented interlacing by making a wall below the surface 6 feet from the back wall, but that is a matter of choice. Your ventilation will be more than ample, but it is best to have enough, and we never recommend any one to put up a cheap house who prefers having such structures built in a substantial manner.

PRUNING SCARLET GERANIUMS (G.).—No rule should be driven too hard. In pruning Scarlet Geraniums freely you get more healthy robust plants, and can keep them for many years, if so disposed, in the same sized pots. By adopting the Harry Moore style the plants are kept in the same pots or boxes. Any extra strong shoot is pinched, to make all regular; but after a few years little of this will be required, as there will be comparatively little growth. Dryness in the end of autumn will cause the leaves to fall, and after that the soil should be dryish, not drier. In spring most likely a few twigs that seem sickly will want removing, and very likely the point of a shoot if not well ripened. Such plants are best kept like a faggot in winter, but free from frost. There is so little growth that there is little chance of legginess. When the buds break a little water is given, and most likely a little rich surfacing. The plants will not bloom early but continuously all the summer; but, as a rule, the individual trusses of bloom will be smaller than on plants cut back, repotted, &c. We lately saw, at Putteridge Bury, four massive plants of Tom Thumb, in the centre of beds, covered with bloom from top to bottom—the only plants in the flower garden plunged in pots, and they had been in the same pots sixteen years and were treated as above stated.

PROTECTING GREENHOUSE FLOOR FROM DRIP (Idem).—We should prefer the edging of zinc with the pipe for the stage, and cannot understand about the pipe throwing its heat up to the centre of the house. The stages might also be rendered watertight by pitch, as practised at Mr. Bewley's, near Dublin. A few ornamental stages so done might be placed in the house, with a drain-pipe in the centre, and when desirable that could be taken by a pipe to a pail underneath. We once had vases to fill with flowers and keep healthy, but no water must be seen on the floor. We had wood pedestals made, painted and sanded to resemble part of the large vase, and in these we placed zinc troughs, which we emptied before they were full. The plan you propose would be the best in your circumstances, if you dislike the look of the saucers. Prune the side shoots of the Solanum jasminoides to two buds.

TERRACE BEDS AT CRYSTAL PALACE (Noro).—About the long line of beds on the terrace you have made a mistake. The centre of the long beds is planted with Geranium Crystal Palace Scarlet, on each side Geranium Christina (pink), with an edging of Verbena Purple King. The circular beds between are planted with Calceolaria Aurea floribunda, edged with Geranium Flower of the Day.

LOBELIA SPECIOSA NOT PROSPERING (C. P.).—Yours is not a solitary case, as we have seen more than one other of a similar kind. Usually Lobelia likes more moisture than we had the last July; but as this cannot always be accorded, we would advise you next season to try seedling plants. They thrive better than those from cuttings, though they are not always so good a blue nor so upright in habit. The Lobelia does not furnish much foliage at any time during the summer, and when the plants are not healthy it is all flower-stem, so that many growers are obliged to cut down a plant in August to encourage a growth of shoots for cuttings.

ORCHARD OF DWARF APPLES (W. R. J.).—If your trees show undue luxuriance two or three years after planting, then take them up and replant them, but such as incline to bear well will not require this. The distance to plant them will depend on the size you propose to allow them to grow; but we should think about 12 feet from tree to tree will allow them to be trained bush fashion. If for pyramidal standards they may be a trifle closer, but we should not expect more fruit by being nearer than 12 feet.

ALLIUM FRAGRANS, IXIAS, SCILLA, AND SPARAXIS (Bulbiferum).—Allium fragrans is a native of the West Indies. Plant it in a pot of light rich soil now, and keep it in a warm greenhouse. Ixias and Sparaxis are in many cases deserving of pots, but we have known them also do well out of doors. They are somewhat of the same habit as Tritonia—a sort of pseudo-bulb. We should think they would do in the midland counties if planted in dry ground, and slightly protected if very severe weather occurred. Scillas are hardy, but are nevertheless favourite potted plants, especially S. præcox, S. autumnalis, and others, which force well and form lovely objects early in spring. In this respect they differ widely from the Ixia and Sparaxis, which only flower in summer, and often rather late in that season. All the Crocuses are hardy.

FILBERT TREES 20 FEET HIGH (Filbertum).—We fear your Filbert trees that have been allowed to grow unpruned until they have attained the height you mention are useless, for to cut them down to the ground would only be to obtain a crop of rods better suited for cask hoops than for making a good bearing plant. We should uproot the trees and plant others, not on the same ground however, and at an early period in the coming winter. You will see some notes in our pages on the pruning they require. No plant that we know, not even the Vine, requires more judicious pruning than the Filbert.

VARIOUS (A Constant Reader, Dublin).—Skimmia japonica will stand sun as well as a Camellia. If the leaves are dry the sun's rays will not blight the leaves. It does well in a pot, kept in a cold pit or cool greenhouse. Daphne cneorum does well in a pot. Both this and Skimmia japonica do moderately in towns, and they bear wind well, as all plants of low growth do. Variegated Holly will grow almost anywhere, and in anything. Yuccas require to be strong and a moderate age before they flower. We do not know what size the pot Lapageria rosea was shown in; but we have seen very fine plants on an umbrella trellis in 13-inch pots.

STOPPING PIPE-JOINTS—PIPES REQUIRED (A Regular Subscriber).—Ram some hemp or tow, with or without red lead, to the socket of your joint, just to make a rest there. Make some Portland cement into a thick paste, fill the joint thoroughly with it, and, as soon as it shows signs of setting, smooth the joint all round with a putty knife, and go on with the next—or, rather, go on with that whilst the first is firming a little. To commence in March you would need at least 54 feet of four-inch piping. To do so from December to January you would need nearly double—fully from 70 to 90 feet. If you can start the Vine in the pot early, and plant when the ground is warm, so as to give no check, you gain time, but at the expense of much additional care and labour. If by spreading out the roots in a cold soil, or any other carelessness you check the Vine, you will lose more than you gain.

SIX FUCHSIAS (Donegal).—Smith's—Sanspareil, Conspicua (white corollas), Mammoth, Hercules (double), Banks'—Minnie Banks, Mars, or Madlle Trebell. Azaleas—Tricolor, Perfection, Etiole de Gand, Flag of Truce, Distinction, Sir H. Havelock. If address is sent a correspondent says that, for the sake of the old country, he would send a few cuttings of Fuchsias.

CABBAGE APHIS (D., Newcastle).—Your Cabbages are infested with the Cabbage aphis. Soot water is a drink they do not like, and dry soot sprinkled on the leaves and stems whilst wet will make them shift their quarters; and if the stems be sprinkled with soot prior to an attack they rarely touch them, for no insects like the presence of soot. It really is marvellous to see how plentiful insect plagues are becoming, and yet people advocate the destruction of small birds, insects' natural enemies. We rarely are troubled with any insects, but we shelter birds.

OVER-VIGOROUS PEAR TREE (Idem).—Dig out a trench half the height of the tree from the stem, and cut all roots that you find within 3 feet from the surface. Thin out the branches to a clear foot distance between each, cutting all foreright shoots close, not leaving so much as an eye; but the short spurs you must not prune at all, nor shorten the extremities of the branches unless the space allotted to them is exhausted. Remove all strong-growing shoots the season following by disbudding, and use the knife but sparingly.

KILLING WORMS IN A TAN-PIT (George Sim).—Be cautious about using salt to kill worms in a tan-pit in which Ferns are plunged. The least touch of salt is fatal to most plants of the Fern tribe, whether it be the root or fronds that are in contact with it. As the pots as well as the tan are full of worms, you must drive them out of the whole. Take a hogshed, say holding sixty gallons, and in this put 28 lbs. of fresh-burned lime, pour sixty gallons of water upon it, and let it stand forty-eight hours. Having stopped up the holes in the pots, deluge them with the clear lime water for a couple of hours. The worms will come to the surface—we need not say "Catch 'em and kill 'em." Water the tan with the lime water, and clear the worms away as they appear. Then sprinkle some ammoniacal liquor from the gas-works on the tan, or a thick sprinkling of salt will answer the same purpose. You may then cover the surface with ashes, and if you put small pebbles 3 inches thick over the ashes the appearance will be improved and the drainage kept open. Gleichenias need no syringing if the atmosphere be kept moist; but a gentle sprinkling refreshes them in hot dry weather.

TANK-HEATING CUCUMBER-PITS (J. Hill).—We have not a word to say against tanks of any kind provided they are secure; but you had better have all tanks or all pipes for bottom heat, or both pipes and tanks—that is, the pipes passing through the tanks. But now as to the tanks, one the length of the house, and 2½ feet wide and 4½ inches deep, would be ample for bottom heat if you have two three-inch pipes for top heat—better two four-inch pipes though. These should be heated independently of each other. Supposing the tank to be covered with slate, we would place on that 4 or 5 inches of rubble and then 15 to 18 inches of soil, and then the foliage should be 15 inches from the glass. Were there not other reasons for the tank, we would run two four-inch pipes for bottom heat and two for top heat. On the bottom heat pipes we would place above and all round them 4 to 6 inches of open rubble, and on that the soil, with drain-pipes open at top for sending moisture among the rubble when desirable.

VINE-BORDER (An Old Subscriber).—Let there be a thorough drainage, and then form it of a mixture of one half turfy loam (top-spit of a pasture), one quarter charred rubbish and crushed bones, and one quarter limey rubbish and bricks broken small.

NAME OF GRAPE (—).—The specimen sent is not the Muscat Hamburgh, but the White Tokay. We have mislaid your letter, and therefore cannot give your nom de plume.

NAME OF SEA ANIMAL (A Devonshire Rector).—The marine animal found in vast numbers on the sands at Northam Burrows, near Bideford, is an Acaleph belonging to the genus Veletta, either V. limbosa or V. cyanea.—W.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (T. C. Limerick).—Your Fern is the Asplenium lanceolatum, a rather rare Fern in England, and this Fern varies much, according to the situation, in size, form, and even texture. The other plant is the common purple Dead Nettle or Archangel, Lamium purpureum, an annual—a weed. (M. D.).—It is the Colerus frutescens, which used to be called Plectranthus frutescens, a native of the Cape of Good Hope, and was introduced to this country in the year 1774. We are aware that this is a favourite plant among the middle and humbler classes of Londoners, and by them called the Nettle Geranium. It will live in almost any gloomy place if protected from frost. (George Cottrill).—Your plant is the common Feverfew, Pyrethrum parthenium. There are various forms of this plant, from good double quilled down to semi-double and the common single. (P. H. G.).—Sentellaria cordifolia, a native of Mexico, introduced in 1844. (Rosa Dartle).—Calystegia pubescens flore pleno, a beautiful climber from China. (Barr and Sugden).—The plant brought from Holland, where it grows freely and is there called "Nacht Schatten," or "Night Shade," is only the common Marvel of Peru.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

SMALL BIRDS EYED BY A POULTRY KEEPER.

It seems to us that few persons are better able to take part in the "bird murder" controversy than those who keep poultry, especially if it is in confinement. The constant feeding and attention give them the opportunity of judging the habits of these benefactors or depredators, as may be. We have tried in every way to master the subject by observation, and we can come to one conclusion only. Where small birds, for lack of any other are driven to their natural food, we believe they are most useful; but where they can feed in the poultry-pens at all times they become fat and lazy, and forget or neglect the work of usefulness for which they were sent.

As we look out of the window where we are now sitting, we can see a man going round with a pail of meal from pen to pen. The flocks of sparrows, chaffinches, &c., follow him, by flying from tree to tree, and dropping into each pen as fast as he leaves it. Now, we are sure these birds do no good. There is no occasion for them to seek food. They are privateers, or rather pirates, and take all that comes in their way. They thrive upon it. We swarm with every description of them, and we like to see them about; but it is often a great annoyance to us.

When we have occasion to remark on the consumption of food, we are always reminded we have forbidden the destruction of small birds. We do not much approve of Indian corn for poultry, but in hard weather, and, indeed, partially all the year round, we are compelled, as a measure of economy, to feed with it, to the consternation of our small pests.

We follow the controversy in the *Times* with great interest, and the opinions of the amiable and talented men who have written on the subject are entitled to the respect and admiration of all. But it seems to us we want to hear more from practical people who deal with nature and with facts as they bear on pounds, shillings, and pence, divested of everything like poetry or sentiment.

The time of year is rightly chosen, as any one who undertakes to diminish the numbers of his small birds must do so in the approaching winter. It cannot be done at any other time. Nature has endowed them with the property of self-preservation. The gun, if one bird at a time be shot at, is too slow to accomplish destruction. A man kills a dozen, and seeing only few about the place, fancies he has "pretty much thinned them," but the truth is they are crafty. After they have been shot at a few times, they "skedaddle" the moment they see any one; but they are always on the look-out. Few people have any idea of the difficulty of extirpating small birds by means of the gun. A gentleman complaining at a dinner-table of the bad sport he had when shooting, said he wished "black-birds and thrushes were game: the swedes were full of them, and he could have killed thousands." His friend made a bet with him that he could not kill a hundred in the day, shoot one at a time. It was accepted, and he was allowed the whole day, but he killed only between forty and fifty. We knew an instance where a sick person wanted larks, and three men went out with guns to kill as many as they could. Notwithstanding it was in the winter, and they had hundreds of acres of cultivated land to go over, the three did not bring in four dozen. We have seen a *positive* and *literal* bushel full of small birds killed in one day in a pen during a hard frost, when the ground was covered with snow. We believe small birds every year consume large quantities of food, for which they make no return. We have tried to side with those who preserve them, but we cannot. Our experience is that when there is no fruit, they fly to the poultry-pens; but that under all circumstances they are at peace with grubs, caterpillars, *et hoc genus omne*.

MIDDLETON AGRICULTURAL SOCIETY'S POULTRY SHOW.

THIS Show was held at Middleton on the 17th inst. The poultry classes were confined to birds of the present year, with the exception of Turkeys and Bantams. For all varieties, excepting Ducks, Geese, and Turkeys, there were three classes—viz., cockerel and pullets, single cockerels, and pairs of pullets. Considering the period of the year when this Show is held, the Committee were certainly justified in excluding old birds from competition. At a Lancashire show it might have been anticipated that the Game and Hamburg classes would have been most conspicuous for merit, but they did not contain so many pens of really good birds as the classes allotted to Dorkings, Cochins, and Game Bantams.

The classes for Black-breasted and Brown Red Game stood first on the list, and amongst these the class for pullets was probably the best. In the class for cockerel and pullets of Any other variety of Game, the first and second prizes were given to Duckwings. The first-prize cockerel promises to make a superior bird; but before he is again exhibited we

would suggest that the operation of dubbing should be completed, as the half-trimmed state in which he was shown was far from making the most of his appearance. The Spanish were not remarkable; but the Dorkings were very good, and the pens exhibited by Mr. Statter and Mr. Newton were excellent. Of Cochins there were no less than thirty-two pens, many of them containing birds of striking merit. The chief prizes fell to the lot of Mr. Stretch, Captain Heaton, and Mr. Hindle. The Hamburg classes were hardly above an average; and in the Golden-spangled class it was difficult to find the requisite combination of comb, ear-lobe, and accurate markings of the feathers. The Game Bantams were a good class. One exhibitor of a good pen had the misfortune to be shut out from competition, as his birds were put into the wrong class, owing, it was stated, to his not having affixed the proper label to the hamper. The arrangements of the Show were good, and the weather remarkably fine, which, with the immediate proximity of Manchester, and the dense population of Lancashire, secured an influx of company which few of our agricultural shows can command.

The following is a list of the awards.

GAME (Black-breasted and other Reds).—First, T. Dixon. Second, J. Firth. Third, R. Parkinson. Highly Commended, T. Statter. Commended, J. Holme; G. Taylor. Cockerel.—First, J. Firth. Second, J. S. Butler. Highly Commended, W. Hargreaves. Pullets.—First, E. Parkinson. Second, T. Statter. Highly Commended, C. W. Brierley.

GAME (Any other variety).—First, J. Holme. Second, T. Dixon. Third, R. M. Harrison. Cockerel.—First, J. Firth. Pullets.—First, J. Hall. Second, W. Bourne.

SPANISH.—First, S. Siddall. Second, J. Clewes. Third, S. Tyldesley. Cockerel.—First, H. Beldon. Second, N. Cooke. Pullets.—First, T. Rogers. Second, J. Siddall.

DORKINGS.—First, T. Statter. Second, J. F. Newton. Third, T. Crowther. Highly Commended, J. F. Newton; E. Smith. Cockerel.—First, T. Statter. Second, J. F. Newton. Highly Commended, S. Farrington. Pullets.—First, T. Statter. Second, E. Leech.

COCHIN-CHINA.—First, T. Thatch. Second and Third, Captain Heaton. Highly Commended, Captain Heaton. Cockerel.—First, E. Ramsden. Second, Captain Heaton. Highly Commended, S. Handley. Pullets.—First, F. M. Hindle. Second, Captain Heaton. Highly Commended, R. Ward; J. Frankland; J. Hartley; C. J. Samuels.

HAMBERGUS (Golden-pencilled).—First, Carter & Valient. Second, A. M. Higgin. Third, A. Nuttall. Commended, J. Dixon; T. Wrigley. Cockerel.—First, A. M. Higgin. Second, A. Bamford; J. Firth. Third, W. Wrigley. Second, J. Wellens. Highly Commended, A. Bamford; J. Firth.

HAMBERGUS (Silver-pencilled).—First, A. Boyd. Second, C. Moore. Third, H. Beldon. Highly Commended, E. Hindle; J. Dixon. Cockerels.—First, J. Andrew. Second, A. Fielding. Pullets.—First, D. Hillingworth. Second, E. Hindle.

HAMBERGUS (Golden-spangled).—First, J. Andrew. Second, H. Carter. Third, G. Whittaker. Highly Commended, J. Dixon. Cockerel.—First, J. Lancashire. Second, Hopworth & Coldwell. Pullets.—First, J. Andrew. Second, J. Ogden. Highly Commended, E. Smith.

HAMBERGUS (Silver-spangled).—First, J. Dixon. Second, J. Fielding. Third, J. Altham. Highly Commended, Mrs. Sharp. Cockerel.—First, H. Beldon. Second, R. Ward. Pullets.—First, E. Stevenson. Second, J. Collinge.

HAMBERGUS (Black).—First, R. Goodwin. Second, J. Hope. Third, H. Beldon. Cockerel.—First, J. Dixon. Second, G. Whittaker. Highly Commended, R. Tattersall. Pullets.—First, J. Jacques. Second, R. Battersby.

ANY VARIETY NOT PREVIOUSLY CLASSED.—First, H. Carter. Second, J. Dixon. Third, J. Smith. Highly Commended, H. Lacy; W. Bowley. Cockerel.—First, J. Dixon. Second, J. Frankland. Pullets.—First, J. Dixon. Second, S. Farrington.

BANTAMS (Game).—First, J. W. Morris. Second, N. Cook. Third, J. D. Newsome. Highly Commended, J. Whitworth; W. Laurinson. Cock.—First, R. M. Stark. Second, J. W. Morris.

BANTAMS (Any other variety).—First, H. Beldon. Second, E. Hutton. Highly Commended, C. Walker; R. Gledhill. Cock.—First, C. W. Brierley. Second, J. Magnell. Highly Commended, R. M. Stark.

DUCKS (Aylesbury).—First, R. M. Stark. Second, Mrs. Seamons. Highly Commended, Mrs. Seamons. Commended, D. Reynolds; F. W. Hindle.

DUCKS (Rouen).—First and Second, T. Statter. Highly Commended, J. Holme. Commended, E. Leech.

DUCKS (Any other variety).—First, J. B. Jessop. Second, J. Dixon. GESE.—First, D. Reynolds. Second, D. Ashbrook. Highly Commended, D. Reynolds.

TURKEYS.—First, J. Dixon. Second, E. Leech.

The Judges were Mr. Teebay, Preston; Mr. J. H. Smith, Skelton, near York; and Mr. Harrop, Middleton.

SPEED OF CARRIER PIGEONS.—It appears from a recent trial made at Bourges, that Carrier Pigeons can still compete in speed with railways. Last week 145 Pigeons were liberated at Bourges at five o'clock in the morning, to decide a wager. The first prize was gained by a Pigeon which arrived at his Pigeon-house at Verviers, at fifty-four minutes past twelve. The last arrival was at eleven minutes past one. Thus, in less than nine hours, these birds performed a distance of 150 leagues, or 375 miles—a speed which no French railway can equal.—(*The Building News*.)

TARPORLEY (CHESHIRE) POULTRY SHOW.

THIS was the first meeting of this Show, and it was remarkably well attended by all classes. The entry was good, and there were some very good birds exhibited.

SPANISH.—Prize, W. Woolley, Eubury, Tarporley. Highly Commended, J. Sheen, Tilston.

DONKINGS.—Prize, J. Hinde, Utkinton. Highly Commended, S. Hignite, Onston; Sir P. Egerton, Bart., M.P., Oulton Park.

GAME.—Prize, J. Sheen, Tilston. Highly Commended, O. Carter, Cote Brook.

HAMBURGS (Spangled).—Prize, J. Sheen, Tilston. Highly Commended, Dr. Seller, Tarporley.

HAMBURGS (Pencilled).—Prize, Lord Binning, Eaton Banks, Tarporley. Highly Commended, Dr. Seller, Tarporley.

ANY OTHER BREED.—Prize, S. Rogerson, Utkinton. Highly Commended, J. Sheen, Tilston; Lord Binning, Eaton Banks; Mrs. Carter, Iddenshale.

DUCKS (Aylesbury).—Prize, Lord Binning, Eaton Banks. Highly Commended, S. Hignite, Onston.

DUCKS (Rouen).—Prize, S. Hignite, Onston. Highly Commended, J. Young, Fourlenden.

TURKEYS.—Prize, S. Walley, Utkinton. Highly Commended, Sir P. Egerton.

GESE.—Prize, J. Sheen, Tilston. Highly Commended, Lord Binning, Eaton Banks, Tarporley.

Mr. Heath, of Nantwich, was the Judge.

LOSSES AT POULTRY SHOWS.

I WISH to call the attention of your readers to the conduct of the Committee at the Wakefield Show. My pen of Duckwing Bantams took the first prize there and disappeared. Mr. Crossland, the Secretary, wrote me word that they were gone, but the hamper directed to me was still there, so he believed they must have been stolen. This pen I had priced five guineas, as I usually do, but I believe it was worth more, and the same birds were entered for several other shows, so they are a serious loss to me.

Now, for several days I made no claim, but left it to Mr. Crossland to make inquiries if the birds could be heard of. At last, without my claiming anything, he sent me £4, saying he would send the remainder, but had no more money with him. Next morning, however, I heard from him, that the Committee disapproved of his having sent even the £4, saying all the Bantams in the Show were not worth £5 altogether. If so they must have taken a very great deal of trouble for a very poor result, for the Wakefield Show must have been a very shabby affair. So on the 12th I wrote to Mr. Wainwright, the general Secretary, urging my claims. After several days' delay he answers me, saying the Committee consider I am well paid already.

Now, I complain of this treatment. It is not that my loss (£1 5s.) is so much, but that I consider the conduct of the Committee dishonest. I do not believe I should have received the £4 even, if it had been left to them, for they seem to blame Mr. Crossland for sending it. One of their rules certainly is, that they will not be liable for any loss or mistake. But that must surely mean loss in going to, or returning from the Show, or the death of a bird there, for which they are of course not responsible. But it was in their power to have a stricter watch kept at the Show, and I think if a man has another's property committed to his care, and loses it through negligence, he is bound to make it good. Nobody would send to shows if, besides the risk of the railway journey, he thought his birds were not safe in the Show. If they are so negligent that they allow birds to be stolen from the Show, I believe they are legally bound to make it good, and that they are morally bound, I think, no gentleman can doubt.

Again, if there is no claim on the Committee, what is to hinder a dishonest member of the Committee, or untrustworthy servant, appropriating valuable pens to himself out of the Show, when such a careless watch is kept?—WILLIAM LAWRENSEN, *Allestree, near Derby.*

[There is very little doubt that the Committee of the Wakefield Poultry Show are legally liable for the five guineas; but even if not compellable by law, yet it would be politic for a Committee under such circumstances at once to state their readiness to pay. Above all things they should neither offend exhibitors generally, nor the exhibitor who has been robbed in particular, by depreciating the merits and value of their birds. On the other hand, an exhibitor who loses his birds as Mr. Lawrensen lost his, should remember that the Committee make no profit out of an ex-

hibition, but endure much trouble and risk, with a chance of benefit only to the exhibitors. When such a loss does occur, we think that there should be mutual consideration; and if the Committee had come forward in a gentlemanly spirit, and claimed a fair deduction, Mr. Lawrensen, we think, as we certainly should have advised, would have agreed to be satisfied with the sum sent by Mr. Crossland.—EDS.]

LEIGH (LANCASHIRE) POULTRY SHOW.

THE above Exhibition of poultry is held in conjunction with the Leigh Agricultural Show, and time has proved that since the addition of this branch the annual meetings of this Society have continually increased in popularity, till at length the poultry to be met with at the Leigh Shows will hold good position among such meetings; and the continually thronged state of the show-yard thus set apart for poultry evinced that the general taste of the neighbourhood is decidedly favourable to poultry-culture. The Committee are justly entitled to every praise for the great care and attention they devoted to the fowls entrusted to them; and should they on future occasions carry out the numbers of the pens consecutively throughout the whole Show, they will certainly find it an improvement. This will also do very much to prevent the various mistakes arising from commencing the numbers afresh in each class—a feature our constant experience never knew introduced without leading to inevitable confusion. On the present occasion a pen of the best Black Polands with white crests were necessarily disqualified through being thus placed in the wrong class, although they would have been by very far the best pen if entered properly. Again, no doubt, the non-consecutive character of the numbers caused many pens of chickens to appear in the classes for adults and *vice versa*, to the compulsory discomfiture of the various exhibitors.

At this season of the year to expect adult fowls in good plumage would be to hope against conviction, there being, as anticipated, scarcely a pen of old birds in barely passable feather. No doubt this fact of moulting caused many owners to withhold forwarding their entries on the supposition they could not win. In reply it should be always remembered that at this time of year all parties are in the like "fix," so that to withdraw them from competition is mistaken policy.

Many of the *Game* chickens were exceedingly good, as were most of the *Hamburghs* also. The first-prize old Golden, spangled *Hamburghs* were undoubtedly a credit to any show. The classes for *Cochins* were especially good. In the old birds of this kind Captain Heaton headed the list with his well-known Partridge-coloured pen. These truly excellent birds are being sadly too heavily taxed by continuous exhibition to maintain health and condition, a month or two's quietude being now indispensable to future success. The *Game Bantams* were good; and the *Geese*, *Turkeys*, and *Ducks* were particularly so. Although the previous day's soaking rain had rendered passing to the ground a difficulty, a fine day for the Exhibition made all things satisfactory and pleasant, consequently a large attendance resulted.

GAME (Black R.d.).—Prize, A. Horrocks, Leigh. *Chickens.*—First, P. Unsworth, Lowton. Second, J. Hazelden, Tyldesley. Highly Commended, P. Unsworth; C. W. Brierley, Rochdale.

GAME (Any other variety).—Prize, H. Smith, Bedford. *Chickens.*—First and Second, J. Wood, Haigh. Commended, C. P. Ackers, Bickershaw.

SPANISH.—First and Second, N. Cook, Atherton. *Chickens.*—First, N. Cook. Second, P. Unsworth.

COCHIN-CHINA (Any colour).—First, Captain Heaton, Manchester. Second, J. Elliott, Westleigh. Commended, Captain Heaton. *Chickens.*—First, S. Handley, Pendleton. Second, Captain Heaton. Highly Commended, Captain Heaton. Commended, N. Cook, Atherton; J. Elliott.

DONKINGS (Any colour).—First, S. Farrington, Astley. Second, J. Mangnall, Leigh. *Chickens.*—First and Second, J. Bullough, Atherton. Highly Commended, E. Leach, Rochdale; T. J. Lancashire, Bedford; S. Farrington Commended, S. Farrington.

HAMBURGS (Golden-pencilled).—First, C. W. Brierley, Rochdale. Second, T. Wakefield, Golborne. *Chickens.*—First and Second, J. Hazelden Tyldesley. Highly Commended, Miss H. Leigh, Bedford; S. Fielding, Middleton.

HAMBURGS (Silver-pencilled).—Second, J. Platt, Deace. First, withheld. *Chickens.*—First, S. Fielding, Middleton. Second, J. Platt, Deace.

HAMBURGS (Golden-spangled).—First, N. Marlor, Denton. Second, H. Fletcher, Leigh. *Chickens.*—First, N. Marlor. Second, G. Whittaker, Horwick. Highly Commended, G. Whittaker.

HAMBURGS (Silver-spangled).—First, J. Fielding, Middleton. Second, J. Hazelden, Tyldesley. *Chickens.*—First, J. Hazelden. Second, L. Kirkman, Leigh; J. Fielding. Highly Commended, J. Hazelden.

POLANDS (White-crested).—First, S. Farrington, Astley. Second, H. Smith, Bedford. Commended, S. Farrington. **Chickens**.—First and Second, S. Farrington.

POLANDS (Any other variety).—First and Second, S. Farrington, Astley. **Chickens**.—First and Second, S. Farrington.

GAME BANTAMS (Any variety).—First, R. Gerrard, Atherton. Second, A. Horrocks, Leigh. **Chickens**.—First, J. Platt, Deane. Second, C. W. Brierley, Rochdale. Highly Commended, J. W. Morris, Rochdale; W. Eaton, Westhoughton; R. Gerrard; N. Cook, Atherton. Commended, C. P. Ackers, Bickershaw.

GAME BANTAMS (Any other variety).—First, S. Farrington, Astley. Second, J. Mangnall, Leigh. **Chickens**.—First, C. Walker, Haultax. Second, R. Gerrard, Atherton.

ANY DISTINCT VARIETY.—First, F. Bullough, Chowbent. Second, J. Elliott, Westleigh. **Chickens**.—First, E. Leech, Rochdale. Second, J. Elliott. Highly Commended, J. Elliott. **Cock**.—First, A. Horrocks, Leigh. Second, C. P. Ackers, Bickershaw.

DUCKS (Aylesbury).—First, E. Leech, Rochdale. Second, J. Dean. **DUCKS** (Rouen).—First, T. Fothergill, Lostock. Second, T. Wakefield, Golborne. Highly Commended, E. Leech, Rochdale; J. Bullough, Atherton; C. P. Ackers, Bickershaw.

ANY VARIETY.—First and Second, C. P. Ackers, Bickershaw. Highly Commended, W. Sutton, Haydock (Brown); T. Wakefield, Golborne (Brown); S. Farrington, Astley; F. W. Earle, Prescott.

GEES.—First, J. Southern, Kenyon. Second, L. Walls, Westhoughton. **Goslings**.—First and Second, J. Southern.

TURKEYS (Any breed).—First, T. Fletcher, Bolton. Second, G. Jackson, Bedford Lodge (Black).

The Judges were Mr. Hewitt, of Eden Cottage, Sparkbrook, Birmingham; and Mr. Smith, of Middleton.

DODDINGTON (CHESHIRE) POULTRY SHOW.

This Show was held on the 15th inst. Some of the poultry were remarkably good, particularly the first-prize pens of Spanish, Game, and Dorking.

SPANISH.—First, W. Woolley, Bunbury, Tarporley. Second, J. Groucott, Houghton. Commended, A. Moses, Weston; C. Groucott, Bunbury.

DORKINGS.—Prize, T. Burgess, Burleydam.

GAME.—First, T. Burgess, Burleydam. Second, T. Whittingham, Batherton. Highly Commended, S. Edwards, Nantwich; C. Groucott, Bunbury. Commended, T. Whittingham; S. Acton, Hatherton House.

ANY OTHER VARIETY.—First, G. Williamson, Nantwich. Second, T. Burgess, Burleydam. Highly Commended, G. Williamson. Commended, C. Groucott, Bunbury; T. Parton, Chorlton.

TURKEYS.—First, T. Burgess, Burleydam. Second, Mrs. Featherstone, Hunsterston. Highly Commended, Mrs. Turner, Blackenhale. Commended, O. Lunt, Rope.

GEES.—First, T. Burgess, Burleydam. Second, T. Whittingham, Batherton. Highly Commended, J. Edwards, Weston; W. Smith, Hunsterston. Commended, T. Whittingham; O. Lunt, Rope; Mrs. J. Edwards, Hunsterston.

DUCKS.—First, T. Whittingham, Batherton. Second, Miss R. Hayward, Blakenhale. Highly Commended, T. Burgess, Burleydam. Commended, J. Edwards, Doddington; S. Sutton, Hastingon; C. Barnett, Blakenhale.

Mr. Heath, of Nantwich, was the Judge.

STAFFORDSHIRE AGRICULTURAL SOCIETY'S POULTRY EXHIBITION.

THE whole of the specimens competing at this Meeting were by the rules of the Staffordshire Society confined exclusively to birds of the present year—a feature that necessarily added most materially to the interest of those poultry-maneaters who were anxious to ascertain the probable success of our principal breeders at the large exhibitions now so closely approaching. Although a very few cases did occur that left the determination of age a somewhat open question, it is most gratifying to us as public journalists to record the fact they were far less, in point of numbers, than our past experience taught us to anticipate. Decision on the part of our poultry judges, by disqualification, has doubtless done much to put down a practice that tends in no slight degree to daunt the more scrupulous exhibitor, who would only exhibit fairly and honourably undoubted chickens.

The morning of the Show was a really bright sunshine, though towards the evening the anticipated change was verified. Nevertheless this Meeting was exceedingly well attended, every train adding its hundreds to the general numbers that during the day visited the showyard regardless of the weather.

In this Exhibition the *Game* classes stood first. In the Black-breasted and other Reds a most unusually promising pen of Black Reds, exhibited by Mr. John Stubbs, of Stafford, were placed first, and we certainly expect to hear of them ere long as standing favourably on other prize lists. In the class for Any other variety of Game fowls, Duckwings and Greys stood pre-eminent, although some very good Whites were in the field.

In *Spanish* the competition was excellent, and certainly

the Stafford Show bespeaks that this aristocratic breed still has many staunch supporters, and that they who win in 1864 must look keenly to their colours.

In *Grey Dorkings* Viscountess Holmesdale left competition quite in the rear, although several really superior pens were on the lists. In *Silver Grey Dorkings* the Rev. Thomas O'Grady, of Ashbourne, took both prizes, some excellent White ones also competing.

In *Buff Cochins* it will not be a matter of surprise to most of our poultry readers to find Mr. Stretch, of Liverpool, heading the poll, Viscountess Holmesdale being the exhibitor of a very reputable second-prize pen. In the *Brown* and *Partridge-feathered* varieties of *Cochins*, Mr. Edward Tudman, of Whitechurch, stood quite aloof from his rivals. Surely this excellent pen could not be the pen delayed till too late for competition at the recent Islington Show, for such being the case the Railway Company were undoubtedly the cause of defeat in that instance. In colour they are the most perfect we have seen for some time past, and both they and the second-prize pen are well-matured chickens.

The competition in all four classes of the *Hamboroughs* was universally good. There was, in fact, scarcely one indifferent pen throughout.

The *Turkeys* were really first-rate, being well grown and in equally good condition.

In *Geese* and *Aylesbury Ducks* Mrs. Seamons held undoubted sway, so much so as to distance competition altogether. In *Rouen Ducks* several excellent pens were entirely thrown out by the admission of a faulty-billed Duck. We must again state that green-billed Ducks are inadmissible altogether. Three pens of excellent *Buenos Ayrean Ducks* were present, although we have seen them exhibited in better feather.

In the class for *Extra poultry*, for which no prizes were offered, we particularly noticed some capital *Grey Geese*, and a no less covetable pen of *White Cochins-China* fowls.

We cannot conclude our remarks without expressing our satisfaction in finding that year by year the progressive improvement of this Society has been marked—certainly in no instance more so than on this occasion. The untiring efforts of the Committee to insure public good opinion have thus realised their just reward.

GAME (Black-breasted and other Red).—First, J. Stubbs, Stafford. Second, H. Snowden, Braford. Highly Commended, J. Stubbs; W. T. Locker, Stafford. Commended, W. T. Everard, Leicester; W. T. Locker.

GAME (Any other variety).—First, W. T. Everard, Leicester. Second, G. Swift, Stone. Highly Commended, W. Pares, Derby; T. Ball, Stone.

SPANISH.—First, J. Clews, Walsall. Second, G. Lamb, Wolverhampton. Highly Commended, W. Woolley, Tarporley; J. R. Rollard, Bristol; J. Stephens, Walsall.

DORKINGS (Coloured, except Silver Greys).—First and Second, Viscountess Holmesdale, Linton Park, Staplehurst. Highly Commended, J. Copple, Prescott. Commended, E. Tudman, Whitechurch.

DORKINGS (Silver Grey or White).—First and Second, Rev. T. O'Grady, Ashbourne (Silver Grey). Highly Commended, W. T. Everard, Leicester (White). Commended, Lady Bagot, Kugeley (Silver Grey).

COCHINS-CHINA (Cinnamon or Buff).—First, T. Stretch, Ormskirk. Second, Viscountess Holmesdale, Linton Park, Staplehurst. Commended, C. Banbury, Wolverhampton; G. Lamb, Wolverhampton.

COCHINS-CHINA (Brown or Partridge-feathered).—First, E. Tudman, Ash Grove, Whitechurch. Second, T. Stretch, Ormskirk. Highly Commended, E. Tudman.

HAMBERGH (Golden-pencilled).—First, Messrs. Carter & Valiant, Poulton-le-Fylde. Second, J. Weetman, Stafford.

HAMBERGH (Silver-pencilled).—First, C. Moore, Poulton-le-Fylde. Second, J. Holland, Chesnut Walk, Worcester. Highly Commended, G. Griffiths, Worcester; Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Commended, J. E. Powers, Biggleswade, Beds.; G. Griffiths, Worcester; Mrs. Wolferstan, Stafford Hall, Tamworth.

HAMBERGH (Golden-spangled).—First, J. Leech, Newcastle. Second, T. May, Wolverhampton. Commended, G. Brook, Huddersfield; J. Leech.

HAMBERGH (Silver-spangled).—First, Mrs. Wolferstan, Stafford Hall, Tamworth. Second, J. Leech, Newcastle. Commended, E. T. Holden, Walsall.

TURKEYS.—First, J. Coxon, Freeford, Lichfield. Second, W. T. Lockyer, Tillington. Highly Commended, J. Brasington, Barlaston, Stone. Commended, Mrs. Wolferstan, Tamworth; W. T. Locker, Tillington, Stafford.

GEES.—First, Mrs. Seamons, Hartwell, Aylesbury. Second, J. Brasington, Barlaston, Stone.

DUCKS (White Aylesbury).—First, Second, and Highly Commended, Mrs. Seamons, Aylesbury.

DUCKS (Rouen).—First, Mrs. C. Browne, Shrewsbury. Second, J. R. Rollard, Bristol. Commended, Mrs. C. Browne; J. R. Hulbert, Cirencester.

DUCKS (Black East-Indian).—First, J. R. Jessop, Hull. Second, Mrs. Wolferstan, Tamworth. Highly Commended, W. T. Locker, Stafford.

EXTRA POULTRY.—Highly Commended, R. M. Lord, Wolverhampton (White Cochins-China). Commended, Rev. E. C. Perry, Stafford (Grey Geese).

Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, near Birmingham, officiated as the Arbitrator.

WATERFORD FARMING SOCIETY'S POULTRY SHOW—SEPTEMBER 17TH.

On this occasion the following were the awards:—

SPANISH.—Medal, W. Joyce. Commended, H. Jones.
COCHIN-CHINA.—Medal, W. Joyce. Highly Commended, C. N. Bolton.
Commended, H. Jones.
DORING.—Medal, J. Wall. Commended, W. Joyce.
HAMEBURGS.—Medal, C. N. Bolton. Commended, J. Wall.
DUCKS (Aylesbury).—Medal, C. N. Bolton. Commended, W. Joyce.
DUCKS (Rouen).—Medal, W. Joyce. Commended, C. N. Bolton.
FANCY CHICKENS.—Medal, W. Joyce. Commended, H. Jones.
GESE.—Medal, F. G. Bloomfield.
BEST COLLECTION OF POULTRY THE PROPERTY OF ONE EXHIBITOR, NOT LESS THAN FOUR LOTS.—Silver Medal, W. Joyce.

[This ought to be called "Joyce's Exhibition" we think.]

WHITCHURCH AND MALPAS POULTRY SHOW.

THIS very successful Meeting took place on the 23rd inst., and some very good specimens of every class were exhibited.

SPANISH.—First and Second, W. Woolley, Bunbury.
DORINGS.—First, E. Tudman, Ash Grove, Whitchurch. Second, T. Burgess, Burleydam.
GAME.—First and Second, T. Burgess, Burleydam. Highly Commended, Miss Sadler, Heath Cottage, Whitchurch; J. Plate, Newton.
DUCKS (White Aylesbury).—First, J. Ravenshaw, Ash, Whitchurch.
Second, J. Groucott, Haughton. Highly Commended, T. Ravenshaw.

The Judge was Mr. Heath, of Nantwich.

PERFORATED ZINC FRAMES—DRIVING BEES IN BAR-HIVES.

In reply to "A. B. C." I may state that I cannot see much difference between the perforated zinc frames and Mr. Woodbury's wooden ones. They would not facilitate his seeing the work a whit better—from the side window I mean.

With regard to driving bar-boxes, I must say that I often resort to this practice as involving much less trouble than any other mode of expelling bees from such hives—that is to say, where the bees are in force. But then my hives are chiefly located in bee-houses, and not in the open air, as Mr. Woodbury's are. This makes all the difference as to the ease or difficulty of removing bar-combs. It is most troublesome work in a bee-house. For this reason I carry my hives out and drive them, which I find the quickest method. Will Mr. Woodbury pardon my questioning his opinion as to bees been "driven upwards" by simply removing the top board of a bar-hive? Certainly they will not be easily driven thus.—B. & W.

PARTHENOGENESIS—REGICIDAL ATTACKS ON QUEENS.

THOUGH familiar with the works of Bonner, Huish, Huber, Bevan, and Dr. Dunbar, &c., it is only a few weeks since I knew anything respecting the doctrine propounded by Dzierzon of unmated queens being able to lay fertile or rather drone eggs. I am anxious to possess Mr. Woodbury's evidence, being somewhat incredulous respecting the statement.

After hearing of parthenogenesis, I took the queen from a hive in order to get a few artificial ones. I got several just as they were about to leave their cells. Of two in particular, one was hatched on August 21st, and the other on the 23rd, two days after. The one born on the 21st was allowed free egress, and on the 1st of this month was put into a newly-made glass unicomb with a goodly number of bees. They were fed liberally, and on the 7th I found her laying in the new-made comb. She proved very fertile, and at this moment eggs (workers'), and sealed-up brood are abundant. But more of her immediately. The other queen, born on 23rd, was put into a box with a little comb and honey, and with nearly the same quantity of bees, and in a place where the temperature was about equal with the place where I

had stationed the glass unicomb. Neither queen nor bees were allowed egress beyond the bounds of a room in which they could take an airing. Yesterday (September 21st), the queen being now twenty-nine days old, I dislodged her and the bees from the box; but although a little comb was made, and some food stored up, there was not a vestige of life in the form of brood. If Huber be right, she is now destined to be the mother of drones only. I have not learned how long a time must elapse before she begins to lay in her unimpregnated state.

But with the queen born on the 21st, in the glass unicomb, though so fertile, the bees acted strangely yesterday. Their becoming unsettled, and buzzing a good deal, led me to open the shutter, when I found a queen treated as a strange queen, and closely matted over by a cluster of bees. I thought, as there was no other queen in the hive, that a stranger had by some strange mistake entered, and dispossessed the rightful sovereign. But, no: all my other hives had their respective queens, and it was their own rightful sovereign they were strangling. For several hours I laboured to relieve her, but the persecution never abated, and this morning she was lying almost suffocated on the bottom of the hive, firmly enclosed in a cluster of bees. I took her from them, fed and revived her, and after a lapse of six hours have again presented her. But she has again been seized and imprisoned as a stranger. I am confident they will kill her. During the time I removed her the bees were quite tranquil, and busy emptying their feeding-trough.

Queens evidently leave a scent behind them in their course, which the bees can detect several hours afterwards. Her track or trail, I apprehend, is the medium of making her presence in the hive most generally known. Can her scent or odour, then, have undergone some change in its character, offensive or otherwise, that the bees no longer recognise their own mistress? Or, when from any cause it is necessary to have a new queen, does the instinct of the bees lead them to dispatch the old whilst material for making the new is to be had?—R. S.

P.S.—September 23rd, after ten hours' confinement the queen has now in some measure regained her liberty.

[Dzierzon's works have not been translated, but the evidence in support of parthenogenesis is detailed in Siebold's "True Parthenogenesis in Moths and Bees," translated by Dallas, and published by Van Voorst. In Nos. 25 and 30 of THE JOURNAL OF HORTICULTURE are articles from my pen on the subject. The first recapitulates the facts and reasoning in support of the doctrine, whilst the second details my own repetition and verification of Siebold's microscopic investigations, which really place it beyond cavil.

Huber was mistaken in limiting impregnation to a period of twenty-one days. I have known a delay of thirty days without any ill result. Your virgin queen reared and kept from the drones so late in the season may not—nay, most probably will not—lay eggs until the spring: but lay fertile eggs she most assuredly will, if you can keep her alive long enough—drone eggs, if she remain a virgin—worker eggs, if by any chance impregnation should have taken place. Let no one fancy that I speak thus positively without sufficient warrant. I have repeatedly reared queens too late in the autumn for impregnation to be effected, and these have invariably turned out drone-breeders the following spring, after which a *post mortem* examination has demonstrated the fact of their virginity.

Regicidal attacks by workers on their own queens are much more frequent than is generally imagined. Many instances of this kind have already been related by me in the pages of THE JOURNAL OF HORTICULTURE, but I have not yet been able to frame any theory by which they may be satisfactorily accounted for.

There is no doubt that queens leave a track or trail behind them which is noticed by bees some time afterwards; but although bees recognise their own queen when brought into contact with her, it is by no means certain that they can identify the track or trail of any particular queen after she has passed. Besides, what ground have we for presuming a sudden change in the scent or odour of a young and fertile queen that is apparently almost worshipped by her subjects one hour, only to be rigorously imprisoned the next, and ultimately put to death without mercy by these same subjects, literally the children of her

own body? Virgin queens appear especially liable to these assaults, but in their case they seldom terminate fatally. The period of their return from a successful wedding flight seems also to be frequently selected for these attacks, since more than once on releasing a young queen from imprisonment I have plainly distinguished the undoubted sign of fecundation described by Huber. A mature and prolific queen may survive the first few attacks; but, when once commenced, they are generally repeated at uncertain intervals until they terminate fatally. This sometimes takes place with perfectly capable queens in the prime of life, and even occasionally at a season when their loss entails the certain destruction of the whole community. As I said before, I can frame no theory which will account satisfactorily for these apparently inexplicable facts.—A DEVONSHIRE BEE-KEEPER.]

HONEYDEW, &c.

COLONEL NEWMAN has quite mistaken my meaning in supposing that I doubted the existence of honeydew, so-called; I have never doubted it, having almost every summer seen something of it in dry hot weather. I have also had ocular proof, once only, however, that bees will frequent the oak when covered with honeydew. What I doubt is if bees often collect it. Colonel Newman, I perceive, does not say that he has seen hive bees collect it, or how often he has seen them. My notion is that they collect it very rarely, and only in bad seasons, just as they frequented our raspberry bushes last summer, when honey proper was scarce. Can no one else of your numerous apianian readers throw light upon the subject?

What will Colonel Newman say if "B. & W." with the convivial *nom de plume* be the same individual as "A COUNTRY CURATE" of former days—now in truth "a beneficed clergyman?" To help him to recover the shock I will at once put in a disclaimer to the reading which attributes my assumption of the initials "B. & W." to my presumed admiration for or indulgence in that vulgar beverage, "brandy and water." I can assure him that I neither smoke nor tipple, and I hope he will believe me. In a more charitable spirit the excellent Editor-in-chief of this periodical interpreted "B. & W." to mean "Back & Welcome," thus expressing his own kindly feeling at hearing of my safe return home from the antipodes. My own explanation remains to be given. I assumed these initials in the joy of my heart at finding myself promoted to a benefice in the advanced diocese of "Bath and Wells." Here I am anchored after a circumnavigation of the globe, and able to continue my hobby of bee-keeping with little prospect of interruption. Colonel Newman will understand by this confession that "A COUNTRY CURATE," who "was then an experimental bee-keeper, and would not allow of many failures," still survives as an experimental bee-keeper, and does not allow of many failures.—B. & W.

DRIVING BEES INTO EMPTY HIVES.

I AM exceedingly obliged to Col. Newman for his kind wishes, and highly appreciate his good opinion, whilst I am perfectly certain that his observations are never penned in an unfriendly spirit.

In reply to his question as to how often the experiment has succeeded of depriving bees of the whole of their combs, and driving them into a new hive, I may state that I performed it on two swarms of the current year, purchased in the country in the beginning of July. These I drove out of their well-filled hives, as related in page 78, and placed them in boxes furnished only with a few pieces of empty guide-comb attached to the bars. On bringing these two colonies home last week, I found both boxes filled with combs and crowded with bees, the nett weight of each being about 20lbs. My only other experiment of this kind was made on the 22nd of June, 1861, with a purchased swarm which had issued on the 9th of the previous month. This I drove into a perfectly unfurnished straw hive; and although the season did not permit of its doing quite as well as in the two more recent instances above related, it made combs and partially stored them. A little food would have enabled these bees to stand the winter, had I not required their

combs and their personal services for the propagation of Ligurians.

Although the three instances above related are the only ones in which I have tried the experiment during summer, I am in the habit of forming many stocks every autumn, by driving condemned bees for all the old-fashioned bee-keepers I am acquainted with within a radius of four or five miles of my residence. These I bring home and put into frame-hives (generally two or three lots of bees in each hive), furnished with such pieces of comb as I possess, supplemented, possibly, by a little brood-comb or nearly empty comb cut out of their own hives, and purchased of their proprietors. Liberal feeding sets these populous colonies comb-building, and usually stimulates their queens to recommence egg-laying, so that the result is a number of strong and healthy stocks, which rarely fail to survive the winter, and by their prosperity in after years fully repay their cost and the time and trouble devoted to saving their lives by—A DEVONSHIRE BEE-KEEPER.

OUR LETTER BOX.

TOULOUSE GESE (*A Great Goose*).—They are much larger than any of our common English birds. They form an excellent cross. That with the Chinese is not judicious, as, even if increase of weight were attained, it would not be of choice quality. The merits of Toulouse are large size, great weight, and exquisite quality. We have seen them 25 lbs. each, and 18 lbs. in running condition.

EAR-LOBES OF BLACK BANTAMS (*Mrs. H. T.*).—It is not essential for Black Hamburgs to have white deaf ears, because the lack of them is not a disqualification. Instance: if all the competitors in a class had red ears the prizes would be awarded. If out of twenty competitors only three had white deaf ears, and in every other particular the pens were equal, the white deaf ears would turn the scale certainly.

POULTRY SHOWS (*An Exhibitor*).—There is no Journal in which "all" poultry shows are advertised. Committee make a great mistake in not advertising, for there is no doubt many persons, like yourself, "would send birds to many shows which are not advertised did they know that those shows were to be held." It is not uncommon for a Black Spanish fowl to acquire a white plumage by moulting.

GROWTH OF FOWLS (*A Poultry Fancier*).—The answer to all your questions must depend much on the condition in which birds are kept: thus a well-fed Dorking or Cochin will be full grown at eight months, but it will not be at its heaviest. A Spanish fowl takes rather longer. If in perfect health, and the weather be favorable, a fowl will moult thoroughly in two months. The older they are the longer the process. If a Cochin is to weigh 10 lbs. at maturity, we should be content to find him weighing 5 lbs. at four months, or even 4 lbs. A pound per month is good growth.

FEEDING POULTRY FOR EXHIBITION (*P. B.*).—Feed your Dorkings frequently on ground oats mixed with milk. Do not shut them up. Wash their legs and feet before they are sent. Feed the Aylesbury Ducks well on oats and bran, and give them very clear spring water. Let them out in the meadows only when the frost is on the grass—this will help to keep their bills pale, and if they are yellow they will not win.

VULTURE HOCKS IN COCHIN-CHINAS (*White-Cochin-Breeder*).—Vulture hocks have never been deemed desirable in any breed of Cochins, and have always been considered a disadvantage, amounting almost to disqualification. Some Brahmans are shown with this appendage, but they are never prizetakers. They belong only to the Sultans, Ptarangsans, and some others.

CREST OF THE CRÈVE CŒUR (*Idem*).—It is better that Crève Cœurs should have no white feather in the crest; but, like Poles, they get them as they grow older. The crest of the Crève Cœur is totally different from the Poland, inasmuch as it falls back like a Lark crest, and is not required to be more than that. We will describe them next week.

DISCHARGE FROM FOWL'S NOSTRILS (*W. W. Cooke*).—It would have made the question easier to answer if you had stated what the breed is which you think have "the blacks," as some are not liable to the diseases others are prone to. If they are suffering only from cold, bread steeped in strong ale, and given three times per day, will cure them. If they are Spanish, and have the black rot, which comes with discharge and ends in a positive wasting, it is incurable.

FEEDING DRIVEN BEES (*S. D. S.*).—Driving bees into empty hives is dangerous work which should be attempted by none but an experienced apianian, and by such a one only when he has an especial object in view. You will see by an article in another column that Mr. Woodbury has done it only on three occasions during summer when he was in urgent want of broodcombs. The formation of stocks in autumn by driving condemned bees is a different matter altogether, and is a very interesting experiment if performed by those who do not mind the trouble and expense of the copious feeding necessary to enable the bees to furnish their hives with combs, and store these combs with food before winter. You had better permit your old stock to swarm next summer, and unite it to the swarm by driving in the autumn, or drive and unite the bees to another stock if you are desirous of breaking it up at once.

BEES ATTACKED BY WASPS (*Gardener*).—Release the bees immediately, and if they are not dead (confinement by means of putty being very likely to put the finishing stroke to the mischief which was in progress), ascertain their state by turning the hive up towards evening. If it be still populous the bees will probably hold their own, by your simply contracting the entrance so as to admit of the passage only of a single bee. If it be weak the entrance should also be contracted, but the attack should be eluded by removing the colony to a new situation at a distance of not less than a mile and a half. In a few weeks the annual frosts will probably rid you of the plague of wasps, and then the persecuted bees may be restored to their original position.

WEEKLY CALENDAR.

Day of Mnth	Day of Week	OCTOBER 6—12, 1863.	Average Temperature near London.			Rain in last 36 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 61.3°, and its night temperature 43.1°. The greatest heat was 79°, on the 6th, 1834; and the lowest cold, 25°, on the 11th, 1860. The greatest fall of rain was 1.00 inch.

KING CROQUET AND FLOWER-BEDS.

NEW monarch has entered our gardens—an innovator, a tyrant. Perhaps—for there is hope even in the worst cases—he may become an improver, or rather he may cause improvement. His name is “King Croquet.” Hundreds, perhaps thousands, of ladies are his devoted servants, and during the last spring and summer have been each week extending his dominions; and, of course, where ladies take the lead gentlemen follow—bound thereto by duty—doubly bound by inclination.

Your poetic readers will remember Cowper's lines descriptive of the wonders wrought by Brown, the rural designer of the last century—

“Lo! he comes!
Th' omnipotent magician, Brown, appears.
He speaks—the lake in front becomes a lawn.”

Now, this present tyrant, King Croquet, does not turn lakes into lawns, but at any rate he is fast turning flower-beds into lawns. For instance: There is my neighbour the Vicar of Blankton, a rigid old bachelor, yet having many nieces. He therefore must make room for Croquet on his lawn; and lo and behold! his pretty flower-beds are nearly all gone. Is not Croquet a king? Then there is my new neighbour, the recently appointed Rector of Dashborough, in laying out his garden (new rectors have new tastes, or, as the Scotch say, “New lairds mak new laws”), has just squeezed in two or three beds under his drawing-room windows, but King Croquet has all the rest of the lawn to himself. Is not Croquet a tyrant? Then there is the dear old Incumbent of Thorp-Sleepy, with an austere wife, and six daughters exceedingly like mamma. Dear old man! he told me in strict confidence and with a woeful smile, that “he was not only hen-pecked but chicken-pecked.” Well, of course, his hobby—some nice low-standard Rose-beds, are clean swept out of the way to make room for Croquet. But worst of all—for there is yet a worst—there is the Squire of Cham-paign, who has two little square flat fields of lawn on two sides of his house; he, having given up one entirely to Croquet, has covered up the beds on the other side for uniformity's sake. Is not King Croquet a despotic monarch indeed? Wherever I look, on whatever side of me I glance, I find that during this year's spring and summer Croquet has reigned supreme; and, rely upon it, reign on he will for many a year, for Croquet is a famous game, it amuses all, and mamma's of large broods of marriageable pullets tell me it is decidedly conducive to matrimony.

But is there no hope? Is all dark—no light in the picture? Must Flora vanish? I trust not. A tyrant has come indeed, but another is gone. For the last ten years we proprietors of small gardens have had the Gera-

nium fever (usually of a very Scarlet type)—forgive the pun, dear reader. Why, on my little lawn I had eighteen beds. Happily I was not so deeply guilty as some of my neighbours, for I did not destroy my dear old mixed borders. But it has been Geraniums everywhere; for Calceolarias, Petunias, and Verbenas have not borne their fit proportion, being more difficult to keep alive and healthy during the winter. My house has for seven months of each year been Geranium-ridden—laundry full, study windows full, dressing-room ditto; and if I go down into my cellar I knock my head against Tom Thumbs hung up (not for their sins as they ought to have been), from the ceiling, but to be planted out next year.

Now I foresee that this Geranium rage will—must—decline before King Croquet; and is there much cause for regret if it does so decline? I think not. Have we not been guilty of a kind of floral elephantiasis, nurturing one kind of plants, “bedding plants,” to the great injury of others—one large swollen red limb or feature, say red nose, while the other features have dwindled and shrivelled to nothing?

At the same time let no reader think that I am insensible to the great beauty of a bed of Geraniums. Far from it: but there are other flowers of equal beauty. Then, too, the bedding plants have become border plants, turning out the rightful inhabitants—the fine, grand, time-honoured, herbaceous, shrubby, sub-shrubby, and bulbous plants. Also, let it be remembered I speak only of small gardens, not of the gardens belonging to our great country houses, where there is room for everything in large portions. But as an example of what I think a garden ought to be, let me speak of one belonging to a near neighbour of mine.

This gentleman would not allow his garden to be dressed out like a “nigger girl,” all red and flaring, but would preserve his borders at least from the intrusive bedding plants. I paid him a visit last April. His garden, though small, was a marvel of beauty. At every five paces of his long border there rose the stately stem and glorious foliage of the yellow Fritillaria; at other distances other colours of the same kind of plants. Then there was every sort of Anemone, from the wild white to the most richly-hued double; “Polyanthus of un-numbered dyes” everywhere; Auriculas; patches of Arabis, and yellow Alyssum, and many other flowers whose names I know not. Indeed, my friend's border was exquisitely beautiful, and not the beauty of flower alone but of leaf. Now had my worthy neighbour yielded to the fashion of the day, this marvel of beauty which I beheld would at that time of the year have been merely a marvel of mould; for say what one will, you cannot grow even bulbs with bedding plants, for if left they are in the way, and if removed they are unripe and so injured. This I found to be specially true of the scarlet Turban Ranunculus, though scarcely a bulb. I must add that I again saw my friend's garden in June, then in July, then lastly in August; and at all times, owing to his cultivating the herbaceous and shrubby flowers, his borders looked pleasing to the eye.

Now, I fondly hope that this despotism of King Croquet may result in good, by bringing us back to the dear old borders with a sufficiency of beds boasting the richest hues which bedders can afford, but not a whole lawn full of beds. King Croquet is fast driving, by force of his cannon-balls, bedding plants, to the right-about. The revolution has begun. "There must be room for Croquet," cry all the girls; so there cannot be room for so many beds. King Croquet forces his way with his *Armstrong* guns, for he is a warrior as well as a monarch up to the times. Let us guide the revolution, and it will become a reformation. Let the peer or the millionaire have various kinds of gardens—they have room, and give whole acres to bedding plants. Be it so: but we little people must make the best use we can of our little means. So let us have various flowers, especially plenty of spring flowers and lots of Roses, bedding plants, and border plants—no prominence given to one kind, but some of all.

"I'll take the showers as they fall,
I will not vex my homos;
Enough, if at the end of all
A little garden blossom."

But let it blossom, say I, with some of many kinds of flowers.—WILTSHIRE RECTOR.

MR. DONALD BEATON.

SCARCELY a week passes but we have inquiries from some of our numerous readers respecting the health of Mr. D. Beaton. So frequent have these inquiries become, and so general does the interest in our good friend seem to be diffused, that we feel it is necessary we should say a few words by way of satisfying this feeling of solicitude. We are happy to be able to say that Mr. Beaton is physically in the enjoyment of the most perfect health; or, as he remarked the other day when we had the pleasure of visiting him, that he was "better now in health than he has been for the last forty years."

The affliction from which Mr. Beaton has been suffering is the rupture of one of the small blood-vessels of the brain. The effusion of blood on the brain caused a slight disturbance of that organ, and affected his memory in an unusual and very extraordinary way. While his memory was perfectly retentive of the leading events of his life, although he could recognise every friend he had ever known, and was as familiar with the distinctions of plants as he ever had been, still he had lost the faculty of naming both his friends and his plants. He knew all perfectly—he conversed freely on any and every topic, but when he came to the proper name of a person, place, or thing, his memory entirely failed him. Still, however, he never withdrew even for one day from the active duties of his garden, and there, in his closely-packed little "experimental," he might be seen from day to day and all day long tending and even talking to his garden favourites.

In such a state it was necessary that Mr. Beaton should desist from literary work until, by the absorption of the extravasated blood, the cause of the affliction should be removed, and until sufficient time had elapsed to permit a healthy restoration of the functions of the parts. It is with much pleasure that we are enabled to assure our readers that this process has proceeded so far that Mr. Beaton is now enabled to name almost all his friends, and particularly those with whom he comes in frequent contact; that he talks fluently about his plants, and that he is now rapidly progressing towards a state which warrants us in hoping that we shall again have his hearty and genial communications in these pages.

Although Mr. Beaton cannot contribute to our instruction and amusement as was his wont, by those communications which of themselves have created and diffused the taste for the modern style of flower-gardening in this country, he is labouring still in another field. Who can tell what stores of beauty are yet to issue from that "experimental?" We have already been charmed with those lovely "Nesegay" Geraniums which owe their origin to Mr. Beaton's skill, and, above all, are we indebted to him for that glorious "Stella," of which we heard one of our most eminent horticulturists say, "If he never raised anything else, that is enough to immortalise him." On a visit we recently paid we found Mr. Beaton "over head and ears" amongst crowds

of seedling Geraniums of all sizes, shapes, and colours such as we never saw before. Among these there were many that attracted our notice by the immense size of the flowers, some of which were as large as a crown piece, and by the novelty and extreme richness and beauty of their colours. One called *Ossian* has already been sent out. The colour is of the richest velvety deep scarlet, with an azure hue at the base of the petals resembling that hue seen in *Cactus speciosissimus*, but of course not so brilliant; another called *Helen Lindsay*, a rose far excelling *Rose Queen* and *Princess Alexandra* both in size and colour; and there were numerous others not yet let out; *Rebecca*, a charming rosy-lilac of great brilliancy and richness of colour; *Amy Hogg*, a lovely magenta, quite novel in colour; and *Indian Yellow*, a large rich-coloured flower of the colour of the yellow in Indian shawls. These are all novelties, perfectly unique, and unlike anything else that has hitherto appeared.

In this way does Mr. Beaton spend his happy hours; and there is but one regret mingled with all this pleasure, and that is that he is debarred from keeping up that weekly intercourse with his friends, which has now lasted for so many years; but he desires us on his part to state that to the many readers of *THE JOURNAL OF HORTICULTURE* who have listened to him so long and so patiently, he desires to be very kindly remembered.

ENCOURAGEMENT TO LOCAL EXHIBITIONS.

DEAL AND WALMER HORTICULTURAL SOCIETY.

IN asking you to depart from your usual rule of not inserting notices of provincial exhibitions by giving place to a short notice of this Show held at the end of last month, I do so, not because I am personally connected with it, or because of the superior excellence of the articles produced, or because it was favoured by the presence of our noble Premier and Lady Palmerston, but because there are a few points of encouragement connected with it which might lead others to attempt what we have done, and thus extend the advantages which flower shows do unquestionably confer on floriculture—advantages of which no stronger proof could, I think, be given than the progress our little Society exhibits.

About five years ago it occurred to a few persons, most of them either small tradesmen or gardeners, to attempt a horticultural exhibition. They had great causes of discouragement in their undertaking. In the whole eastern division of the county of Kent there was not a single flower show; while they had on either side of them, at Wingham and Ramsgate, instances of societies which had flourished for a little while and then died out. However, they were not deterred, and, despite of difficulties, they prepared to launch their little boat. Knowing that I was interested in gardening, I was asked to give it a gentle push by delivering a lecture on "The Pleasures and Advantages of Gardening;" but with that exception, and that was not much, the whole work of setting it on foot was theirs. As usual there were some little hitches—a shoal here and a rock there; one with a crotchet of one kind and another with something else. However, they got fairly afloat, and their first show was held; then in the following year another with increasing interest. They then began to be somewhat alarmed at their success—they had created their Frankenstein, but they were sadly afraid he would gobble them up. Their expenditure had increased, and they felt that if a wet day came they would be seriously affected by it. They therefore proposed to alter their constitution—to make two Committees, one a financial, to be composed of gentlemen, on whom would rest the responsibility of the money part of the concern, and the other a working Committee. These were after a time merged into one, out of the larger Committee a smaller one for managing the Show, &c., being formed. All have worked amicably together, and the Show has each year increased in interest; and with the good feeling at present existing I have little doubt of its continuance.

It is wonderful how great has been the stimulus given to horticulture in our neighbourhood by means of this little effort. There are now between forty and fifty exhibitors in fruits, flowers, and vegetables. Greenhouses and hothouses have been built in many instances in consequence. Persons who hardly knew one flower from another are now

enthusiastic in their pursuit; and the best varieties of the different flowers are to be seen in many a little garden and window where formerly nothing but the very commonest things were grown. This success is to be attributable to several causes. In the first place there has been a loyal working together of both the working man and the gentleman. The latter have not assumed that patronising air which too often mars the very best intentions. They have felt, I believe, that as the real working-out of the details rests on the former, they should in their arrangements be considered as in a position of equality. Secondly, We have been contented with offering very small prizes: thus, our highest award is 10s., the lowest 1s. This has not made any very heavy demand on the liberality of our neighbours, while it has been sufficient to induce the best growers in our neighbourhood (not for their own sakes but for their gardeners), to exhibit. Where large prizes are offered it runs into a large sum, and often considerably tends, under unfavourable circumstances of weather, &c., to drag the Society down. If we were to go on and prosper we might possibly increase them, but at present we feel that we are safest by keeping in shallow waters.

The time of year at which we hold our Show is not a favourable one; but then we are obliged to wait for the advent of visitors who frequent our neighbourhood as a watering-place, and also for the time when out-of-door fruits, &c., can be obtained, without which many of our exhibitors would not be able to come forward; and the main object being the encouragement of gardening in its various branches, we are obliged to study in these little matters what may be most to the interest of all.

There are two classes of exhibitors. In the first are comprised nurserymen, market-gardeners, and gentlemen who employ a gardener in whole or in part; in the second those who cultivate their own gardens. This allows for the admission of amateurs and cottagers, who contend in friendly rivalry together.

Our Exhibition this year was much in advance of all its predecessors. Plants were well grown and novelties were exhibited; while in vegetables I think it would have been very difficult in any part of the kingdom to have beaten those brought forward. Our market gardeners are somewhat famous, and the soil is so excellent that they are enabled to produce most creditable specimens of their skill; while the interest manifested in the Show by all classes of the community shows how much good it has done.

These few facts are brought forward simply to encourage those who are anxious to do anything of a similar character, and who have been deterred by seeming difficulties. As a clergyman I can bear witness to the good effects of such societies in a moral point of view; and anything that tends to improve the taste and refine the minds of our middle classes, as well as to keep the poor man at home, ought to be hailed as a good. We are too much in the habit of considering merely the poor in our arrangements; but I am inclined to think that the small tradesman and persons in a similar class of life ought equally to be the objects of our consideration; and this is one of those agencies which unobtrusively, yet surely, have the effect of drawing away the mind, partially at any rate, from the grosser desires and feelings to those which are more matters of taste and refinement, besides giving an ever-fruitful source of pleasurable enjoyment.—D., Deal.

THE STYRIAN PEAR.

We have long known the Styrian Pear, and we have all the time believed it to be one not possessing any particular merit. Our experience, it is true, has been obtained in the southern counties, and there this variety comes far short of what is required in a first-rate Pear. It happens, however, that soil, situation, and climate affect in no ordinary degree some sorts of fruits; and we were not surprised when our excellent and practised correspondent, Mr. Hill, of Keele Hall, so frequently extolled to us the merits of the Styrian Pear. We must confess to have had some misgivings, notwithstanding the opinion of so good an authority, thinking that he spoke by comparison with some of the finer sorts of Pears in that cold Staffordshire climate with

which he so successfully combats. Determined, however, that his own opinion should not be the only argument brought to bear on the subject, Mr. Hill has sent us a box containing a few of these Pears; and we must confess that, for beauty of appearance, there is no Pear we know to surpass them. The annexed figure is a correct representation of one of the small fruits. The colour next the sun is a brilliant vermilion gradually shading off to a bright citron yellow. The cheek is as if varnished. The flesh is yellowish, very fine-grained, tender, buttery, melting, and unusually juicy. The juice is sweet, piquant, and with a beautiful vanilla perfume.

This is a most delicious Pear, and unsurpassed by any other variety of its season, which is the last week of September and the beginning of October.

Had this Pear been grown in the south, where at this season there are so many of first-rate excellence to compete with it in point of flavour, it is a question whether we should have selected it as a variety of unusual excellence; but coming as it does from a part of the country where it is with difficulty that the finer kinds of Pears can be grown, and where Peaches and Nectarines cannot be grown on the open wall, we hail the Styrian Pear as a valuable acquisition to our collections of fruits, for those late and exposed localities. But to enable our readers to judge of this in all its bearings, we extract from Mr. Hill's letter the following valuable observations:—

"I send you specimens of the Styrian Pear from a graft on the Citron des Carmes. You will observe how beautifully coloured it is. We find it one of the best flavoured Pears we have in its season, and by grafting on several different stocks we have it much longer in succession. Grafted on Buchanan's Spring Beurré, it is fully a month later than on the Citron des Carmes. We have also Marie Louise and Althorp Crasanne grafted on the latter. They are always a few weeks earlier, and of excellent flavour.

The Styrian is not so much grown as it deserves to be. It is one of our best Pears for a standard in this part. Strange to say, there is not one gardener in twenty that knows it. I feel curious to know what you think of it, as it is a Pear not generally met with. We have Beurré Rance and Easter Beurré grafted on the Aston Town. These both come in much earlier and are better-flavoured when worked on the Pear stock. They run smaller, and are always better coloured and of better flavour. I have no doubt that many of our Pears would be improved in flavour by being grafted on the early kinds on a south wall. The same remark applies to Grapes. I find the Frankenthal makes the best stock for grafting, and the Barbarossa the worst."

We should in conclusion remark that the largest Pear sent was 9½ inches in circumference round the bulge, and 4½ inches long; and we would advise all fruit-growers north of the Trent who are possessed of a Citron des Carmes Pear, to cut it down and graft it with the Styrian.

RESULTS OF POTATO-CULTURE BY THE BROMBOROUGH POOL WORKS

HORTICULTURAL SOCIETY.

Our little Society has now passed its ninth season with apparently undiminished vigour, and with equal interest on the part of individual members. The table below exhibits its progressive growth year by year. As it is purely a village Society, the members being almost exclusively of the working classes, it may be interesting to show side by side with the number of articles exhibited the value of the prizes distributed:—

Total Number of Exhibits at the Two Shows.		Total Value of the Prizes Distributed.	
		£ s. d.	
1855	119	8	18 0
1856	294	9	14 0
1857	299	13	3 0
1858	648	22	14 3
1859	648	19	19 6
1860	455	19	16 0
1861	685	22	9 9
1862	614	22	11 6
1863	559	22	8 6

The dry spring caused a great diminution of exhibitions at our first Show this year.

Owing to our favourable position under Price's Patent Candle Company, the expenses of the Society are undoubtedly less than they would be if we had to pay tradesmen for all services that we could not provide within our own body. But it should be understood that ours is a practical working Society, the Company not supporting it solely by their money, but very judiciously giving yearly a subscription equal to the amount raised by the members themselves.

The Society has been, undoubtedly, a means of much gratification, and of no little good in our village. It was, therefore, with much pleasure that we saw a similar Society commence operations in a village near us (Higher Bebbington), under the auspices of the worthy minister, the Rev. G. Troughton, and the leading parishioners; and we hope to hail another Society still nearer to us before another season shall have passed. The Higher Bebbington Society has just completed its third season with every prospect of future success and of increasing usefulness.

Feeling as we do that the encouragement of horticulture has done so much for us, it is natural that we should earnestly desire to see similar societies established in every village in the kingdom. It is certain that the gentry of our country parishes have it in their power to effect much good by giving their patronage and a moderate amount of money aid to such societies, and by laying a foundation for operations, where cottage gardens do not exist, by the appropriation of ground for village allotments.

But we believe that the work of such local societies might be made still more useful by a system of communication between them—that is, by the arrangement of prizes to be competed for by the members of several societies. While the Rev. Professor Henslow, of Hitchin, was living we had the advantage of entering the lists annually with his allotment-holders, for "the largest and best produce from surfaces of ground of 36 square feet each, in Potatoes, Onions, and Carrots." We must confess that the experience of his allottees enabled them generally to beat us, but the spirit of emulation and generous rivalry which this yearly contest excited, has done very much to raise our horticultural work and to promote its success.

It was from the results of the examination of pieces of ground entered for such prizes, that the tables published in THE COTTAGE GARDENER, No. 629; and THE JOURNAL OF HORTICULTURE, No. 32, were compiled. We are very anxious to renew for our own Society some such competition; and should the perusal of this article bring us into communication with some other Society like our own, we shall feel that we are indebted in no small degree to the good offices of the Editors.

We ought to premise that the regulations as to the pieces of ground to be entered, in order to render the results as far as possible representative of fair practical cultivation, are as follows:—"For this prize the Potatoes must be dug from the ordinary plots. Potatoes planted in six-foot-square beds will not be admissible. The surface will be measured, in the case of Potatoes planted in rows, by taking such a length of one, two, or more rows as will with the distance from row to row make up 36 square feet. In the case of Potatoes planted in 'butts,' the width of the alley on one side will be added to the width of the 'butt' in calculating the space occupied by the plants."

Our Potato-results were this year most satisfactory, not only as to "total produce," but also as regards the proportion of good tubers, as the following table will show:—

AVERAGE RESULTS CALCULATED FROM ALL THE PIECES TRIED.

Year.	Number of Pieces Examined.	Calculated Total Produce in Tons per Statute Acre.	Per Centage of Good Tubers.
1858	Record lost.	12½	85½
1859	Ditto	10	83
1860	29	10	67½
1861	51	11	74½
1862	34	12½	82½
1863	41	15½	87

The next table exhibits the results of our trials of the various kinds of Potato here, year by year, averages being taken from all the yields of each kind, except only when a solitary sample of any variety was entered. Any such solitary results have been generally omitted, or else have been classed together under the head of "All other kinds."

Kind of Potatoes.	1858.		1859.		1860.		1861.		1862.		1863.		AVERAGE.	
	Total Tons per Acre.	Per Cent. Good.	Total Tons per Acre.	Per Cent. Good.	Total Tons per Acre.	Per Cent. Good.	Total Tons per Acre.	Per Cent. Good.	Total Tons per Acre.	Per Cent. Good.	Total Tons per Acre.	Per Cent. Good.	Total Tons per Acre.	Per Cent. Good.
York Regent	18	80	12½	88½	12½	41	11.33	70
Lincoln Red	12	87	10	72½	13	78	11.66	80
Kemp (various)	...	10	87	9½	40½	11½	79	12½	72	15½	87½	...	11.95	73½
Pink-eye	9½	98	10½	86	12½	47	10.83	77
Radical	9½	82	11½	82	9	32	10.68	65½
Fuke	11	86½	9	87	9	68½	12½	82	12½	88½	14½	90	11.37	83½
Atterwsmith's Seedling	7	85	10	76½	11½	86	12½	82½	16	84	11.40	83
Prussian Blue	10½	69½	10.25	69½
Scotch Downs	11½	86	14½	88	18½	90	14.83	87½
All other kinds	14½	81½	15	83	14.75	82½

In respect, therefore, both of total yield and proportion of good, the "Scotch Downs" has at present the highest place with us. The second place would be closely contested by the "York Regent," "Fluke," and "Arrowsmith's Seedling," the first having slightly the advantage. This kind has, however, ceased to be grown here, owing, probably, in part to its bad yield in 1860, and in part to the high opinion generally entertained of the Fluke in this neighbourhood.

The largest yield this year was from a kind of Potato, new to us, called "Daintree's Seedling." One piece was planted with it and gave a total yield equal to 22 tons per acre, with 90 per cent. of good. This variety bids fair to become a favourite notwithstanding its being rather deep-eyed.

It was noticed this season both here and at Higher Bebington, that very many lots of Potatoes were much "scabbed." When our six-foot pieces were tried there could not have been on an average one diseased tuber per piece. Since that time, however, we have had much rain, and the peculiar odour of the disease is now plainly perceptible in our allotments in the evenings, and many diseased tubers have been found in plots recently dug.

TRANSPLANTING LARGE SHRUBS.

FROM time to time we have heard much upon this subject from different persons, and the results of their experience have varied as much, if not more, than the different localities from which they have written; added to which, soils and subsoils have a material effect upon all transplanting operations. I have met with parties who strongly advocated that there can be no better period of the year for carrying out improvements and alterations about the grounds of any residence than early in the autumn. They base their argument principally upon the fact, that during the summer months the earth becomes heated to a much greater depth than it is in the other months of the year, and assert that moving a certain portion of earth cannot be done without fully exposing it all to the action of the air, even if the time which the operation takes up is but very limited; that in many instances shrubs will, under these conditions, begin to emit fresh roots in the course of ten days or a fortnight after their being removed; and that they will often, after being so removed, start in the following spring quite as fresh and vigorous as those which have not been removed.

This is one side of the question, and I imagine those who advocate this mode of proceeding reside upon gravelly soils or chalky formations, where the drainage is naturally good, and where the soil never becomes saturated with stagnant moisture, which is sure to cause young and tender roots to become ruptured and ultimately rot away.

Strong soils never answer well for transplanting large shrubs or trees, and I consider it by far the best policy in all such to put in quite young plants. They may look very diminutive for a time, but it is far better to bear with this than to endeavour to give effect at once with much larger specimens. I have seen these have all the care and attendance for a season which could be bestowed upon them, by mulching the ground above their roots, and likewise every now and then giving them copious supplies of water; but after all, many of them would soon become little better than sticks, not half clothed with leaves.

After a season or two, notwithstanding every precaution, it would be found necessary to replant with healthy young plants. These may, and often will, for a season or two, almost stand still, not growing more than a few inches. Nevertheless, they will generally retain all their freshness; though a few of them may lose most of their leaves, still they never present that unsightly and skeleton-like appearance which is sometimes seen as the result of planting much larger specimens in strong soils.

From having had to operate in very different soils in various parts of the country, I may safely state that it is very difficult to transplant large specimens in strong soils; but in those which are light and open, especially when the subsoil is of a similar character, I have repeatedly transplanted large shrubs in the middle of summer, and when the weather was a little showery for a week or two they never lost a leaf by the operation. In a soil of this character

I a few years ago assisted at the removal of many Oaks from 30 to 45 feet high, and the operation was generally very successful. The trees were cut round at some distance from the stem eighteen months before removal; all the roots which were put forth where they were cut were carefully preserved, as well as the ball of earth; but no practical man would recommend this being done in strong adhesive soils, however desirable it might be to produce an immediate effect. I consider it safest to use young and healthy plants, and these, in the long run, will give the greatest satisfaction.—G. DAWSON.

FLORA IN THE COTSWOLDS;

OR, WHAT MAY BE DONE AT THE WORKHOUSE.

I HAVE perused with much pleasure, since becoming a reader of your periodical, the descriptions and accounts of various gardens, public and private, which have from time to time appeared in its pages; and having been invited by a friend to view the garden of the workhouse of the town in which he resides, I left this queen of watering-places (Cheltenham) to spend a day or two with him in the quiet town of Northleach, distant thirteen miles, and lying high up in the heart of the Cotswold Hills. Hundreds of your readers would, I think, be encouraged to take heart and persevere in their favourite pursuit, if they could see what I saw there accomplished by taste, energy, and patience devoted to a charming hobby.

Although now a very quiet town, from the railways having driven all the coaches from the road without coming near enough to atone for the change, Northleach was, when wool and not cotton was the great manufacture of this country, a place of considerable importance, as is still testified by its endowed Grammar School, still forward in a career of usefulness, its fine church, with its beautiful porch, and brasses of the wealthy woolstaplers, standing in an attitude of prayer on the wool-bags, with the emblems of the lamb and the shears, to denote the trade of which these departed worthies were not ashamed. Nor is the town quite likely to be forgotten by the agricultural world so long as the Cotswold breed of sheep maintains its character, and young rams of fifteen or sixteen months old sometimes fetch £100 at the annual ram sales, at which open house is kept for all comers; whilst to sporting readers will occur the names of some of the horses sent out of the training stables of Mr. Isaac Day and Mr. Golby.

But it is to as humble a place as the workhouse I am desirous of calling your readers' attention. At the farther end of the town, on the Oxford Road, stands this edifice, the scene of the gardening labours of the worthy master, Mr. Oughton. To compare small things with great, I may say this building is situated somewhat like the National Gallery (but is minus its pillars, porticoes, and pepper-boxes), being raised up from the road, and entered by a flight of steps in the centre. The terrace whence idlers and men with catalogues look down upon the passers-by, forms here the garden, on reaching which I was ready to acknowledge it was worthy of all the encomiums of my friend who had brought me to see it, and who, having just returned from a holiday trip of about two thousand miles, declares he has seen nothing approaching it. For a comparatively small space there is certainly such a display of colour from plants in beautiful condition, arranged with great taste and judgment, as I have never seen surpassed even at Sydenham.

The garden is laid down in grass, and to the right a border runs down each side—one laid out ribbon fashion, with *Cerastium*, *Lobelia*, *Calceolaria*, and *Heliotrope*, and the other with the same and *Geraniums*, planted on the cross; whilst the centre consists of five oval beds, placed alternately lengthwise and across. To the left on entering, the garden is laid down with turf, but instead of the oval beds we have a large central bed 60 feet long and 10 feet wide, edged with *Cerastium*, followed by *Lobelia*, *Calceolaria*, *Geranium Brilliant*, and a central row of *Trentham Rose*. The effect of this bed viewed from the end, where some steps going down to the little chapel admit of a view being gained of the whole length, with the form of its transverse section, is something superb, whilst the old grey wall over which it is thus viewed is resplendent with the blossoms of the

Tropaeolum Eclipse. The borders in this half of the garden are again planted with *Geraniums*, *Verbenas*, *Calceolarias*, and *Heliotropes* on the cross. The beauty of the garden is further enhanced by a rustic fountain (home-made), summer-house (ditto), and a neat little greenhouse, 24 feet by 11, chiefly the work of the same industrious pair of hands. Wherever there is a spare space or an unoccupied corner, up goes a rustic bed in stages, or some little device, to be rendered brilliant when the bedding season comes by its appropriate plants. A space around the little chapel, rather lower than the rest of the garden, had *Spergula* planted on it, to form a tiny lawn; but *Spergula* has gone to the rubbish-heap, and "*Requiescat in pace*," says Mr. Oughton, and so say I, and welcome the brilliant flowers in its place. Looking with ever so critical an eye on this display, including the carpentering, glazing, fountain, and gardening, with the little forcing-place and large fruit and kitchen gardens at the back, the visitor must be astonished at what an enthusiastic amateur can, almost unaided, accomplish. And when I say to my brother readers of *THE JOURNAL OF HORTICULTURE*, many of the suggestions from whose pages I here saw admirably carried out, "Go and (try to) do likewise," I must add, for their encouragement, that ten years ago the worthy workhouse-master hardly knew one end of the spade from the other.—J. P. K.

RECOLLECTIONS OF A VISIT TO NORTH RODE HALL.

THE RESIDENCE OF MRS. DAINTRY.

THIS beautiful place lies about four miles from Congleton, five or six from Macclesfield, and is easy of access by the North Staffordshire Railway, as there is a station at North Rode, about one mile from the mansion. Having frequently heard of the high-keeping of the gardens at North Rode, and only residing some half dozen miles from the place, I resolved to make a personal inspection of them. I, therefore, journeyed into the neighbourhood in the early part of the month of May, and can testify that the reports were so far from being ill-founded, that the gardens much exceeded my expectations, and I promised myself another visit further on in the summer. I paid my second visit towards the end of August, and, notwithstanding the previous wet week, I found every part of the grounds in the best possible condition.

I entered the park near to the village church, a beautiful edifice, with everything surrounding it indicating wealth well expended. The park is well studded with trees, many of them young in years, and some few bearing the marks of a venerable old age.

On entering the gardens I met with Mr. Chaplin, the respected head gardener, near to a number of span-roofed houses. The first we entered was the stove. In this house there are some fine specimen plants of *Croton angustifolium*, *Croton variegatum*, *Caladium Belleyneii*, *Caladium argyrites*, *Caladium bicolor splendens*, &c. I also noticed some well-grown Ferns down one side of the stove, which was devoted to their growth, and the warm end was set apart for Orchids, all of which were in the highest luxuriance. There were also a few pets of *Anæctochilus* growing under bell-glasses, and which were doing well. *Cyanophyllum magnificum* would soon be too large for the house, and *Alocasia metallica* was growing into a beautiful specimen. Some of the flowering plants were going out of bloom, and many others were being grown on to supply the conservatory which adjoins the mansion.

We next entered a low span-roofed house, which was originally built for a pinery, but that idea having been abandoned, it has been converted into a house for the growth of greenhouse plants to supply the conservatory above named. This house is plain in its construction, yet admirably adapted for the purpose to which it is devoted. Of the kinds of plants grown, I may mention *Fuchsias*, *Geraniums*, exhibition and Zonale varieties; shrubby and herbaceous *Calceolarias*, *Chorozemas*, *Epacrises*, *Boronias*, *Correas*, *Hibbertias*, *Leschenaultias*, *Tremandras*, &c. Near to this house were also cold pits, in which were growing large quantities of *Primulas* and *Cinerarias* of the best named sorts. We next entered a small Melon-house, in which were grow-

ing the second crop of Melons on the same plants that produced the first crop. Judging from the appearance of the second crop which was fast approaching maturity, the first must have been extraordinary. In the Peach-house the fruit was nearly all gathered, but the crop had been excellent.

From the Peach-house we entered the vineries; and here a scene presented itself which I must confess my humble pen is unable to pourtray: the crops of Grapes, especially the Muscats, were such as any gardener in the kingdom might be proud of. A more regular and even crop I never saw, the rafters were filled from top to bottom, and with as great regularity as if the bunches had been placed on by the hand of an artist. The berries were extremely fine, and well coloured, and the bunches of large dimensions.

In close proximity to the vineries is a large span-roofed house, and, as Mr. Chaplin informed me, he puts it to innumerable purposes. In the centre was a trellis running the whole length of the house from the bottom to the top; to this trellis were trained two large Apricot trees, planted in the open border, and loaded with beautiful fruit. In autumn large quantities of late Cauliflowers and early Broccolis are lifted in the kitchen garden, and brought into this house, which may be termed a winter kitchen garden. The Broccolis are succeeded, I believe, by a crop of Potatoes that come in early, herbs, salads, &c. After the vegetables are over, it is used for Azaleas, Camellias, &c., that have bloomed in the conservatory, as these plants will not do very well out of doors in this neighbourhood.

On leaving this house we walked through the kitchen garden, and here I noticed that the crops of vegetables and the smaller fruits were excellent: in fact, they were as good in proportion as the more choice fruits were under glass. Mr. Chaplin is not one of those who in striving to grow good crops of Grapes, or fine specimen plants yet neglect their kitchen gardens, in which you can scarcely see the vegetables for rank luxuriant weeds. On the contrary, every part of the kitchen garden was scrupulously clean and neat, with scarcely a weed to be seen. The varieties of Strawberries grown were Oscar, Rivers' Eliza, Wonderful, La Constante, Sir Harry, and a few others that escape my memory at the present moment, the latter invariably bearing a heavy crop. I also noticed a number of young Apple trees, of the variety Lord Suffield, trained as espaliers, which were doing well, some of them bearing nice crops of fruit. Mr. Chaplin told me that he considered this Apple invaluable at this season of the year, and more particularly in a season like the present, when the Plum crop may be considered a failure. As soon as the smaller fruits are over this Apple comes into use, and keeps up a supply till nearly Christmas.

From the kitchen garden we passed on to a winding walk by the brink of a beautiful lake leading to the pleasure grounds. On this walk there are many objects of interest to the visitor. The first was a nice boat-house by the water's edge containing three good-sized boats, each capable of conveying large parties on the lake. A little distance beyond the boat-house to the right was the ice-house. On this alone an article might be written. It is simply constructed, and yet effective. I suppose it then contained upwards of fifty tons of ice. A little further on was the hardy fernery and rockery, where the water was trickling down the stones, and where a lover of these beautiful plants would wish to linger.

Leaving this lovely dell we came on to a raised terrace walk, where the undulating scenery is stretched before the eye like a charming panorama. Far away in the western horizon might be seen the lofty heads of the shire hills; in the north a hazy glimpse of the Derbyshire hills might be seen in the neighbourhood of Buxton, while to the right in an easterly direction might be seen a hill called The Cloud—so called, I should imagine, from its immense altitude—and which I suppose is the highest hill in the county.

From this walk we entered the flower garden, and here a blaze of beauty meets the eye of the spectator, every bed was full to overflowing. Mr. Chaplin has a happy method of blending colours, and I do not remember two beds being planted alike.

Mr. Chaplin had tried the *Coleus Verschaffeltii* as a bedding plant, but it would not answer, and it had been succeeded by the *Amaranthus melancholicus ruber*, and that

was scarcely giving satisfaction, it being too dingy in its appearance. I noticed a bed edged with *Geranium* Mrs. Pollock; and it may be satisfactory to know that this charming variety retains its robustness of habit and its beautiful and delicate hues even in this northern district. I also noticed another bed edged with *Centaurea candidissima*, which looked well, and another edged with *Tussilago farfara* fol. variegatis; but the lion of the flower garden was *Tropeolum Eclipse*. Mr. Chaplin intends, as soon as the summer-bedding plants are over, to fill the beds with early-flowering bulbs and spring-flowering plants. In the reserve garden for this purpose I noticed large quantities of English and German Wallflowers, *Arabis alpina*, *Arabis alpina* variegata, *Forget-me-not*, &c. On the neatly-kept lawn adjoining the flower garden was a fine specimen of the noble *Wellingtonia gigantea*, its height was 15 feet 6 inches, and the circumference 30 feet.

The last, but not the least, place we entered was the conservatory, and here another sumptuous treat was in store. all the plants were well grown and in good health. I could neither see a plant deficient in vigour nor an obnoxious insect. I may say in conclusion, that Mr. Chaplin was extremely kind and obliging, and spared no pains to point out every object of interest.—QUINTIN READ, *Biddulph*.

THE GARDENERS' BENEFIT SOCIETY.

THE Gardeners' Society is fast becoming the topic of the day amongst us. Even in this locality, remote as it is, there are some who are willing to become supporters of it with all its rules, and wish for its being speedily in operation. There are others who say that it will never be accomplished, because in many of our good places there are men acting as head gardeners who never served a regular apprenticeship, and who cannot stand before some of the Society's rules: consequently their support is lost to the Society, which accounts in a measure for the supineness shown by gardeners in not coming forward to promote the proposed Society, so much needed. A third party will say, "Bah! are we going to be wheeled out of our hard earnings to swell the corporation of our beef-eating neighbours, or to line the pockets of our canny N.B.'s by having them placed over us in this Society?"

This is the substance of several gardeners' discourses, which, to my knowledge, have taken place in this neighbourhood. They invariably have come to the conclusion that if fair play is given in this respect by placing Irishmen in office in the Irish branch of the Society they will cordially give their support to it.—B. CARROLL, *Gardener to J. S. Kirwan, Esq.*

Rendlesham Hall	Lord Rendlesham	Mr. Allan	Woodbridge

THE VITAL POWER OF THE WHEAT PLANT.—At the Lewes Flower Show in August was shown a bundle of corn containing 1551 ears, the produce of a single grain sown in June, 1862, by Mr. Spary, of Chailey. The object was accomplished by what is termed "propagation," or division and redivision of the root. The plant raised from the single grain was divided three times, and replanted. In a month or so these plants were redivided and again planted, and in the following spring a third division of all the plants was made. The result is a good armful of corn, containing 1551 ears; and

as each ear may contain from twenty to eighty grains, the yield of a single grain so treated becomes something incredible.—(*Brighton Guardian*.)

[In connection with this we may remark that Mr. Spary has sent us four specimens of Wheat fairly ranking among the finest we have ever examined. Of these Spary's Prolific takes the lead as a Red Wheat, quite equal to the lead taken by Hallett's Pedigree among White Wheats.]

NEW BOOK.

A Handbook of Vine and Fruit-Tree Cultivation, as Adapted to Sir Joseph Paxton's Patent Hothouses. By SAMUEL HEREMAN. London: Bradbury & Evans.

THIS is a pamphlet of a little over fifty pages, the main feature of which is a treatise on the patent hothouses introduced by Sir Joseph Paxton, and furnishing instructions for their management and the cultivation of the crops they may be employed in growing. The book is illustrated with some excellent woodcuts, representing residences in connection with which these hothouses have been erected; and we must own, that if the buildings produce effects as elegant as they do in the engravings, and we see no reasons why they should not, we should advise our readers who have not seen them to make inquiry about these new houses. The instructions given for the cultivation of the Vine and other crops are essentially practical, and are evidently written by one who has himself performed all the operations before he attempted to instruct others.

TODMORDEN BOTANICAL SOCIETY.

A MEETING of this Society was held on September 7th, at which Dr. Rigby, of Chorley, Lancashire, was elected a member, and Dr. O'Brien, of Ennis, Co. Clare, Ireland, an honorary member.

Among specimens of flowering plants lying on the table were the lovely *Eucharis amazonica*, *Rondeletia speciosa* major, *Meyenia erecta*, a species of *Cypripedium*, *Lilium lancifolium rubrum* (fine), several good varieties of *Petunia*, *Caladium*, *Maranta*, &c., *Aster tripolium*, *Chrysanthemum arcticum*, and *Potentilla dubia*. Among Cryptogams were the beautiful new crested variety of the Royal Fern, *Osmunda regalis cristata*, *Platyloma Brownii*, *Pteris tricolor*, *P. argyræa*, and *P. cretica albo-lineata* (three of the handsomest variegated Ferns), *Asplenium trichomanes incisum*, and a new and most beautiful variety of the same species, provisionally named *serratum*. It is a much-improved sub-aquale. Both varieties form part of the botanical "spoils" resulting from the Society's recent Irish excursion, and are, we believe, the special pickings of Messrs. Nowell and Stansfield.

Mr. A. Stansfield, jun., brought fine examples of the Holly Fern, called often the "Scotch Fern," from its being almost peculiar to the Scottish mountains, lately gathered on Craigcalleach, one of the heights of the great Breadalbane chain; also fronds of a quite peculiar form of *Asplenium viride*, gathered in the same locality; together with a beautiful variety of *Athyrium Filix-femina*, with the pinnae uniformly and most elegantly tasselled, from the neighbourhood of Aberfeldy.

After the transaction of business, conversation turned on the late excursions. Of these there have been three since the last meeting of the Society—the first on the 14th ult., to the highlands of Scotland, the party comprising Mr. J. Fielden (York), and Mr. A. Stansfield, jun.; the second, on the 22nd ult., to County Clare, Ireland, the party comprising Mr. Stansfield, the President, Mr. Nowell, the Vice-President, and Mr. Patman, the annalist of the Society, T. Aitken, Esq., of Bacup, and Mr. Greaves, of Hebden Bridge; the third was a minor excursion.

The highland explorers had the disadvantage of bad weather. They managed, however, spite of almost incessant rain and storm, to rob the "old hills" of not a few of their botanical secrets. Pity that one cannot find a means of propitiating the meteorological powers before starting on a botanical tour!—above all, a botanical tour in the highlands, where the clouds, attracted by the giant hills, distil almost constant floods. Not that any true botanist need to, or

indeed does, take to his heels at the sight of a hand-big cloud—what are cloud and storm to him, seated in the crevice of a rock, mentally engrossed with some beautiful and rare mountain flower? Nothing!—only there is the small matter of the body, which is frail. Walking ankle-deep in wet bog, or scrambling over slippery rocks, one slip from which would bring you to “where adieus and farewells are a sound unknown,” may be pleasant for ten hours running, but for ten days—hardly.

Our neophytes did not return from the Scottish alps without bringing with them that loveliest of all purely alpine British plants, and which is as rare as it is lovely, occurring only in one locality in Britain, the Breadalbane mountains, the *Myosotis alpestris*. It is described as growing in greatest abundance on almost inaccessible cliffs from 300 to 400 feet in perpendicular height on the western side of Ben Lawers, and here it was that our young botanists gathered it, though under circumstances of extreme difficulty and peril, the natural difficulties being heightened by the inclement weather. Ben Lawers yielded them also the rare *Cerastium latifolium*, *C. alpinum*, *Saxifraga nivalis*, *S. stellaris*, *S. hypnoides*, *S. oppositifolia*, *S. aizoides*, *Arenaria rubella*, *Salix reticulata*, *S. herbacea*, *Gnaphalium hyperboreum*, *Thalictrum alpinum*, *Arbutus Uva-ursi*, *Sedum anglicum*, *S. telephium*, *Sibbaldia procumbens*, *Helianthemum canum*, *Campänula rotundifolia flore albo*, *Epilobium alpinum*, *E. alsinifolium*, *Polystichum lonchitis*, *Polypodium alpestre*, *Lastrea alpina*, *L. cristata spinulosa*, *Cystopteris fragilis furcans*, *Asplenium adiantum-nigrum angustatum*, *A. adiantum-nigrum variegatum*, *Lyceopodium selago* (nearly a foot high), *L. selaginoides*, *L. alpinum*, and a host of others.

The Irish excursionists, with not more enthusiasm animating them than the Scotch, were more favoured in the important matter of weather. As a consequence, they returned from Erin with vasculums filled to overflowing—overflowing, too, with botanical treasures of the rarest kind, such as would repay the young enthusiast a journey round the globe. Among the discoveries of the party were not wanting, as we before intimated, plants of that exquisite and rare British Fern, *Asplenium trichomanes incisum*, the fortunate finders being the President and Vice-President. We can imagine the loud and jubilant shouts that arose on these occasions.

Our excursionists trod over acres of the rare *Dryas octopetala*, beautifully in bloom; found in quantity the rare *Gentiana verna* (than which, what British plant, occurring at a moderate elevation, is more beautiful?); saw the exquisite Maidenhair Fern in all its glory and pride, its ineffably delicate fronds being measured by the foot; saw the crenate Scale Fern 1 to 1½ inch, but foot; the beautiful Marine Spideenwort well nigh 3 feet, &c.

Among plants found in plenty, in addition to the above, we may mention *Potentilla fruticosa*, whose myriad golden-yellow blossoms coloured the landscape, *Arbutus Uva-ursi*, *Rubia peregrina*, and *Asperula cynanchica*. Rarer phenomena, too, were found, such as *Trifolium medium album*, *Saxifraga decipiens*, *Prunella vulgaris alba*, *Cochlearia anglica*, *Neottia autumnalis*, *Epipactis rubra*, and *Enonymus europæus foliis variegatis*. In regard to cryptogams, “no end of good things” were the rich reward of the searchers. We enumerate a few: *Polypodium vulgare semilacerum*, *Lastrea Filix-mas stenophylla*, *Polystichum aculeatum* new and beautiful crested variety not yet named, *Lastrea emula* in quantity, *Scelopendrium v. Malcolmsoni*, *S. v. fissile* (?) *S. v. sagittato-projectum*, *S. v. Martiniana* (new), with a score of other varieties of *Scelopendrium*, scalpturate, multifid, crenate, sublineate, supralineate, muricate, lobate and undulate, too numerous to give in detail: they comprise many wholly new to the British pteridologist. Mr. Nowell, also, had fully average success in his *sporidolite*, bringing away with him large numbers of rare Musci and Hepaticæ.

The Irish excursion was not wanting, either, in amusing incident and adventure, as the Vice-president's account of it, given in his usual naive manner, attested. In the wilds of Clare, he it known, every botanist is taken for—a doctor! Great is the gathering of the ailing of both sexes on the appearance of the mystical spud and vasculum.

GROUND VINERIES.—These very useful and interesting structures are coming largely into use. This season Black

Hamburgh Grapes have ripened in them as far north as Manchester. An amateur at Stretford, near Manchester, has within the last fortnight cut from two canes only, each 7 feet long, fifteen bunches of well-ripened Black Hamburghs weighing about three-quarters of a pound each.—*Vitis*.

LAPAGERIA ROSEA OUT OF DOORS.

ABOUT three years ago a friend kindly presented me with a very strong and fine plant of *Lapageria rosea*, because, as he said, he had not heat enough to grow it well. I treated it to plenty of heat, and it very shortly died, probably from very bad management on my part. Not liking to be beaten I purchased another plant of Messrs. Veitch in the spring of 1862. It was very small, and I placed it in a warm greenhouse till about the middle of June, when I stood it out of doors in a sheltered position all through that summer, during which time it made two long and strong shoots from the base. About this time last year it was put back in the same greenhouse; and this year, in June, it was again set out. About a fortnight since I found several bloom-buds on it, and one just expanding, and I can now show what few have seen—viz., a plant of *Lapageria rosea* in bloom out of doors.

I trouble you with this to convince those who, like myself, may not have all the conveniences they might wish for to enable them to follow their favourite pursuit, that it is possible to have this beautiful plant in perfection when very small, and with no more trouble than is requisite to grow an Azalea or a Camellia.—*AN AMATEUR, Guildford*.

SMALL BIRDS.

WE extract the following interesting letter from the *Times*. “In a retired corner of the French department of the International Exhibition there lay a long row of mysterious and rather dingy specimens, which in spite of their unattractive appearance, well deserved a study, even in the midst of the bright and beautiful objects by which they were surrounded.

“They consisted of a very numerous collection of the stomachs of birds with their contents spread out on sheets of paper, with a written description of their contents, the time of the year in which the bird was taken, and other particulars. They were the work of M. Florent-Prevost, the celebrated French naturalist, who for thirty years has been prosecuting his inquiries of this kind, and endeavouring to convince his countrymen of the suicidal folly of which they are guilty in the persistent and indiscriminate slaughter of these beautiful little creatures.

“In taking steps to impress particularly upon our younger people in Australia the mistake they commit in destroying these birds which we are taking such trouble to introduce among them, I have put myself in communication with this kind-hearted and enlightened philosopher, and by his aid I have prepared a tolerably complete list of what is eaten during each month of the year by the more common of our birds. And I think, that this list is worth study at home; when the destruction of small birds by poison and other means is attracting Parliamentary notice, and the un-denied facts are brought before the public of whole tracts of forest land laid waste, and whole countries reduced to famine, by the thoughtless removal of the only effective check upon the ravages of the insect tribe, we really ought to dwell upon that point. The little bird is our only safeguard against a pest, which but for it would soon become overwhelming. As Michelet very well says,—‘The bird can live without the man, but the man cannot live without the bird.’ Were we all to resolve ourselves into one great sparrow club we should all in a few years perish from famine.

“I trust, then, that this list will be found useful; and I would suggest to parents, and teachers particularly, that it might advantageously be cut out and preserved for future use, that the minds of young people might be properly impressed with ideas of the usefulness as well as beauty of the pretty little things that enliven our hedgerows and hop across our paths.

“*Long-eared Owl*.—January, February, and March, mice. April, cockchafers. May, rats, squirrels, and cockchafers. June, mealworms, beetles, and shrew mice. July, mice, ground and other beetles. August, shrew and other mice. September, October, and November, mice.

“*Short-eared Owl*.—January, mice. February, harvest mice. March, mice. April, crickets and harvest mice. May, shrew mice and cockchafers. June, beetles. July, field mice and

birds. August, field and shrew mice. September and October, field mice and beetles. November, common and field mice. December, mice, spiders, and woodlice.

"*Bark Owl*.—January and February, mice. March, April, May, and June, field mice. July and August, mice. September and October, field and shrew mice. November, mice and the black rat. December, mice.

"*Rook*.—January, field mice and larvæ or grub of cockchafer. February, field mice, grub of cockchafer, and red worm. March, grubs and chrysalids. April, slugs, worms, and chrysalids. May, beetles, grubs, prawns, and wireworms. June, cockchafers, eggs of birds, and wood-boring beetles. July, young birds, beetles, &c. August, birds, field mice, weevils, crickets, and grasshoppers. September, grubs and worms. October, grasshoppers, ground beetles, and young animals. November, young rabbits and different insects and grubs. December, different animals and decaying substances.

"*Magpie*.—January, grub of cockchafers, young beetles, and corn and seeds. February, the same and berries. March, the same. April, crickets, water rats, and mice. May, cockchafers, glow-worms, and fruits. June, the same and weevils. July, beetles and field mice. August, birds' eggs and weevils. September, beetles, worms, barley, and grasshoppers. October, grasshoppers, carrion beetles, and green locust. November, grasshoppers, and kernels of fruits. December, grubs of cockchafers, young rabbits, and berries.

"*Jay*.—January, grubs of cockchafers, acorns and berries. February, chrysalids, and different grains and seeds. March, grubs, insects, wheat, and barley. April, grub of beetles, and snails. May, cockchafers and locusts. June, eggs of birds, cockchafers, and beetles. July, young birds, flies, and beetles. August, the same, acorns, grubs and dragon-flies. September, the same and fruits. October and November, beetles, slugs, snails, and grain. December, the same, haws, hips, &c.

"*Starling*.—January, worms, grubs of cockchafers, and the dung of animals. February, grubs, snails, and slugs. March, and April, grubs of cockchafers, and snails. May, the same, and grasshoppers and fruits. June, flies, and grubs of various flies and fruits. July, grubs, freshwater shell fish, and fruits. August, flies, glow-worms, and various beetles, and fruit. September, green locusts, grubs of carrion, beetles, and worms. October, worms and beetles. November, snails, slugs, and grubs. December, hips, haws, and buds of trees.

"*Golden Oriole*.—January, various chrysalids. February, chrysalids and worms. March, grubs and beetles. April, ground beetles and weevils. May, beetles, moths, butterflies, and grubs. June, grubs, grasshoppers, bees, and cherries. July, cherries and beetles. August, weevils, chrysalids, fruit, and worms. September, beetles, grubs, worms, and fruit. October, grubs, herbs, chrysalids, berries, and barley. November, ants and worms.

"*Crested Hoopoe*.—January, worms, grubs, and snails. February, March, and April, the same and birds. May, flies, dragon-flies, and grubs of May-flies. June, water and land snails, flies, &c. July, August, September, the same and woodlice. October and November, snails, flies, and spiders. December, the same and worms.

"*Green Woodpecker*.—January, ants. February, worms and grubs of ants. March, slugs, beetles, and grubs of ants. April, ants and worms. May, red ants and grubs of wasps. June, bees and ants. July, red ants. August, red ants and worms. September, ants and worms. October, grub of ants. November, grub of ants and bees. December, ants.

"*Reed Thrush*.—March, grubs and insects. April, aquatic grubs. May, grubs of house and dragon flies. June, worms, grubs, flies, and May-flies. July, beetles and dragon-flies. August, worms, eggs of insects, and beetles. September, aquatic insects.

"*Great Titmouse*.—January, beetles and eggs of insects. February, grubs. March, winter snails, beetles, and grubs. April, cockchafers, beetles, and bees. June, cockchafers, flies, and other insects. July, the same. August, insects and fruits. September, seeds, grasshoppers, and crickets. October, berries. November, seeds.

"*Blackbird*.—January and February, seed, spiders, and chrysalids. March, worms, grubs, and buds of trees. April, insects, worms, and grubs. May, the same and cockchafers. June, the same and fruit. July, August, and September, all sorts of worms and fruit. October, grubs of butterflies and worms. November and December, seeds and chrysalids.

"*Sky-lark*.—January, seeds of wild plants. February, seeds and corn. March, various insects, worms, seeds, and corn. April, insects, beetles, and corn. May, flies and various insects.

June, grasshoppers, worms, and corn. July, crickets and grasshoppers. August, insects, corn, and seeds of weeds. September, seeds, worms, and barley. October, November, seeds, corn, and berries. December, seeds of wild plants.

"*Redbreast*.—January, insects, worms, and chrysalids. February, insects, worms, and woodlice. March, chrysalids and worms. April, moths, eggs of insects, and cockchafers. May, grubs and beetles. June, flies, moths, spiders, and worms. July, moths, butterflies and woodlice. August and September, the same and worms. October, eggs of insects and aquatic insects. November, worms and chrysalids. December, chrysalids, grubs, and eggs of moths.

"*Nightingale*.—February, grubs and worms. March, the same, and chrysalids and ground beetles. April, flies, meal-worms, beetles, and red worms. May, butterflies, cockchafers, weevils, and grubs. June, spiders, wood-boring beetles, and worms. July, worms, grubs, eggs of locusts, grasshoppers, moths, and flies. August, locusts, glow-worms, weevils, and grubs. September, locusts, beetles, worms, and dragon-flies. October, grubs, worms, and beetles. November, flies and worms.

"*Linnet*.—January, February, March, and April, seeds and berries. May, June, July, August, and September, the same and insects. October, November, and December, berries, seeds, buds of trees, and fruit.

"*Chaffinch*.—January, seeds, berries, and kernels of fruit. February, the same and corn. March, the same and insects. April, moths, flies, and insects of various kinds. May, cockchafers, grubs, and eggs of insects. June, the same and wild fruit. July, the same and grubs of beetles. August, moths and butterflies. September, eggs of insects, worms and seeds. October, wood-boring beetles and insects. November, seeds. December, seeds and buds.

"*Greenfinch*.—January, February, and March, seeds, berries, wild fruit, worms, &c. April, May, June, July, and August, the same and insects. September, October, November, and December, seeds, berries, worms, and wild fruit.

"The *Sparrow* only lives near the habitations of man. It varies its food according to circumstances. In a wood it lives on insects and seeds; in a village it feeds on seeds, grain, and larvæ of butterflies, &c.; in a city it lives on all kinds of *débris*. But it prefers cockchafers and some other insects to all other food.

"In looking over this list critically our sparrow-killers will probably think that M. Florent-Prevost has here and there allowed the advocate rather to interfere with the philosopher, and they may miss some articles of food which it is notorious that birds consume; and in his zeal to show the amazing quantity of insects destroyed by his little *protégés* the proportion of fruit, grains, &c., also consumed perhaps scarcely accords with our less accurate observation. Still these results are obtained by actual inspection, and we may be sure that everything enumerated has been found. And we must remember that these experiments were made in France, and that the food of birds will always be largely influenced by local peculiarities.

"It is worth mentioning that a study of M. Florent-Prevost's specimens showed another important fact ranging beyond the above lists—that many birds, namely, living a good deal upon grain, feed their young entirely on insects, so that they are serving us admirably in this way at a season when insects are most rife, even when the examination of their own stomachs would lead us to denounce them as little better than mere plunderers.

"And here I would draw attention to the value of another set of experiments recently reported in the papers, as suggestive of the incredible quantity of insects destroyed by such agencies. A gentleman took some young Robins and fed them himself, weighing them and their food accurately day by day, to discover what quantity a young bird required to keep it in a growing and healthy condition. As he went on he became more and more astounded at the results; and he found that, taking the common earthworm as a representative of the food, the daily supply required to keep a young Robin in its highest health, laid end to end would reach the almost incredible length of 14 feet. This seems amazing, but those will not hesitate to believe it who have watched the incessant activity during the long hours of a summer's day of a pair of birds with a nest of young. But let us put this and that together when we wish properly to estimate the services of this invaluable little thief-catcher, and with a true conception of the part he has to play among us, let us do what we can to save him from the wanton shot and cowardly poison.

"I am, Sir, your obedient servant,

"*Reform Club*.

"EDWARD WILSON."

KEELE HALL.

(Continued from page 237.)

THE centre-house or conservatory is 50 feet long, 25 feet wide, and 15½ feet in height, deeper ridge-and-furrow roof, and glass all round except against the back wall. The house was well stored with fine plants of Camellias, Azaleas, Oranges, &c., and the roof was rich with streamers of Passion-Flowers, Tacsonias, and Bignonias, so as to give to the whole great ease and naturalness of expression. The entrance front of the conservatory was guarded by two very large variegated American Aloes in dark tubs; and just behind them on two pedestals to the steps, stood two *Humea elegans*, one on each side. These were in pots and were, therefore, so far out of character, for nothing less than an elegant vase ought to have stood in such a position. A walk from this front leads to the park and its nice timber. Looking back at the conservatory (*fig. 1*), the two Agaves, the feathery *Humeas* behind them, and the flaunting streamers and other vegetation inside, made it a pleasing picture.

The vineries and the conservatory in this range were slightly shaded during the summer by what Mr. Hill prefers

to all other modes—as much patent driers is mixed with linseed oil as to give the necessary shade, trying several pieces of glass until satisfied. It stops on all the summer. A little potash and soft soap in water will take it off; but care must be taken not to touch the paint, or that will be taken off likewise.

As a lean-to at the back of this conservatory range is the general show-house for flowers. It is 100 feet long, 11½ wide, 11½ high at back, and 8 high in front. The back air is given through a chamber in the wall, and passes out through the south side above the glass as already described. The stages are formed of slate, supported by columns as elegant as they are economical, being earthenware socket-pipes 1 foot in diameter, the socket forming the base of the column. This house was very gay with Fuchsias, Lilies, Geraniums, &c., and we can fancy its appearance in winter with Camellias, bulbs, &c.; and in spring when the fine collection of Azaleas is in bloom. Opposite the east end of this house is a walk with a ribbon-border on each side lead-

Fig. 1.

ing up to a fine Peach-wall, which here forms the northern boundary of the garden, over which some fine Chestnuts and some beautiful Scotch Firs break the sky outline.

Proceeding still onwards in the same direction, we come to the orchard and nursery garden, being at present a regular repository for fruit, shrubs, Roses, and flowers of all kinds; but which by the removal of the nursery part is to be devoted chiefly to fruit, Roses, and beds of flowers mostly for cutting from, with massive beds of such useful under-shrubs as Lavender, &c., of which large quantities are wanted. The quantity of Cloves and Carnations, &c., here grown would surprise even some regular dealers in these

things, and all for cut flowers. This garden is divided near the centre by a grass walk 8 feet wide and 200 yards long, with a ribbon-border on each side, and planted the same, beginning at the grass with Scarlet Geranium, then Caie's yellow Calceolaria, which does well here, and brought all the associations of our old friend Mr. Caie and the grouping in the flower garden at Bedford Lodge, Camden Hill, vividly before us. We think this Calceolaria is named Kayi, but that is a different thing, and was sent out by the late Mr. Kay, of Finchley. The Calceolaria is backed by the Purple Zehinda Dahlia, and that by Gladiolus, backed again by a good row of Hollyhocks. The Gladioli were not then in

bloom, which rather made a blank. This pleasant walk is again crossed by a noble avenue of beautiful Deodars, each plant being as like and as massive as its neighbours, looking almost as if a mould had been made to fashion them. These were planted twenty years ago, and were raised and replanted in their present regular position twelve years ago. They now stand from bole to bole across the avenue 33 feet apart, and from bole to bole in line 25 feet apart. Not one was injured at Keele in 1861, though hundreds were destroyed in the more sheltered valleys, as at Trentham and other places.

As already noted, the frosts of May had rendered the fruit more scarce than usual; but the appearance of the standard and goblet-trained Apple trees, the pyramidal Pear trees, &c., denoted that in a fine season there would be no lack of fruit. Though we only passed a few hours at Keele Hall, we could have spent a day cheerfully in this general repository alone, there was such a thorough blending of the useful with the beautiful. For instance: In one place in front of these trained trees were fine collections of Roses, half standard and dwarf, grown in beds 4 feet wide, and

surrounded with *Cotoneaster microphylla* edgings, cut 6 inches high and 6 inches across; and then in another place were numbers of beds surrounded with Box similarly managed, and containing collections of herbaceous, and the best bedding plants. In one place, we think here, was a fine piece of *Calceolaria canariensis*, dwarfer in habit and a more soft yellow than *Aurea floribunda*. The west side of this garden is bounded by a fine Holly hedge, and a broad grass avenue separates it from a row of Limes which are to be cut and trained to a definite form. At the north-west corner is a beautiful gate, and a broad gravel walk goes from it along the north side of this garden, backed by perhaps the finest Holly hedge in England. This gate was glazed with strong glass, the first gate I had ever seen so treated. I have omitted to state that from the entrance to the stables a fine view is obtained of the conical-headed Wrekin mountain. From this gate a fine panorama of landscape opens up, terminating with the Welsh mountains; but the currents of wind were frequently so strong that the pleasure of walking was here greatly diminished, and hence, to keep the wind out, and enjoy the views too, the gate

Fig. 2.

has been glazed. This fine hedge (fig. 2) is 200 yards long, 24 feet in height, slopes back out of the perpendicular to the top fully 6 feet, is about 6 feet wide at the top, and we presume is about 20 feet wide at the bottom. After passing the eastern boundary an evergreen arch across the walk from the hedge forms a very pleasing view.

Returning eastward still, we come to the bowling-green flower garden, bounded on the west side with a good Yew hedge, and on most other sides with huge masses of noble plants of the crimson and scarlet *Rhododendrons*, which here escaped the frost of 1861, though destroyed in many lower places. In this garden the beds are in a panel below the walks; and though all were full and good, the magenta

Verbena alluded to already and the *Gazania splendens* and *Golden Chain Geranium* were much above the average. From this garden we wind through masses of *Rhododendrons*, *Hollies*, and other evergreens until we reach a broad terrace walk above the level of the first kitchen garden wall, and from which the whole can be seen at a glance; but if we wish for something more retiring, we have only to step backwards a little to reach the centre of a fine avenue of flourishing Spanish Chestnuts, though not come to their best, the avenue being 400 yards long, and many of the trees girthing from 13 to 14 feet at 2 feet from the ground. Passing onwards through a rockwork and fernery on a lower level, we reach the mansion; and if a shade of regret has

come over us, it is that the fine Deodars, noble Chestnuts, ancient-looking Scotch Firs (girdling from 9 to 11 feet), and Sycamores (girdling 14 feet), do not come in as prominent objects from the principal windows.

Here we had the privilege of meeting the worthy proprietor and being shown by him over the principal rooms of the fine new mansion, most of which are yet not quite furnished. The ceiling of the drawing-room is gorgeous in the extreme, and the wood-carving throughout must be second to few or none. We were almost sorry to find that some of the most elaborate gilding in the rooms was placed over the most beautiful carving in wood, thus almost putting the latter at first sight in competition with gilding over plaster, &c. The gilding seems to hide at first sight not only the rare taste of the artist, but the liberality of the proprietor in securing it. There did not seem to be anything of a make-believe, but everything to be real in the elegant adorning of these fine suites of rooms. Mr. Sneyd told us that at his advanced age he had no idea of building a fresh mansion on the site of the old one, but merely wished to renew a part, but that when that was about to be done the architect surprised him by stating what he deemed then to be an impossible fact—that the foundations of the old house were giving way, though it was based on the sandstone rock. It was, however, true. The rock in places had been thin, with a bed of sand beneath, and there the weight of the house had cracked the rock and caused it to subside. The whole mansion is a beautiful piece of workmanship, built chiefly with a hard pink sandstone found on the estate, relieved with the white Hollington stone found near Alton Towers, and the joints are so fine as to be just discernible.

At the south front there is a nice flower garden in a sunk panel with a graceful fountain in the centre. The beds in the panel were massive and well filled, and surrounded with coloured gravels, which told well. A series of composition-beds were placed on each side on the higher level, and what was planted was equally good; but we were prejudiced against any mere masses of coloured gravels instead of flowers where these form part of the same composition. Besides the general timber, this garden is backed by fine specimens of different-coloured Hollies, Hemlock Spruce, &c.

From the terraces and lawn on the south-east side fine views are obtained of the woods of Trentham and Henechurch. On the bold swelling ground to the eastward the belts formed by Brown have been broken up and now are graced with masses of timber. In the bottom vale beneath you a nice lake has been formed out of several disconnected fish-ponds, and the fine contrast of foliage around that lake afforded by Oak, Holly, Willow, and Hemlock Spruce, Deodars, Scotch Pine, and Pinus pinaster is such as a painter would love to study. On an out-jutting corner prominent from the lawn, and on the opposite side of the lake, is a small piece of rockwork made of the red sandstone. This has been done so closely to resemble nature as to deceive one of the most accomplished geologists of the age. Residing at the hall, he came hurriedly from his bed-room one morning and thus accosted his worthy host:—"Allow me to congratulate you, Mr. Sneyd, on having coal on your property." "Indeed!" "O yes, there is no mistake about it. Whenever the red sandstone dips in a certain way there is always coal." "Always?" "Yes, it is a sure infallible sign." "What if the blocks have been placed in that particular position?"

With this anecdote we take our leave of Keele Hall, and that reluctantly, as, besides being gratified by the superior gardening we went to see, there seemed to be over the whole place such an atmosphere of repose, of comfort, and of happiness. This is not to be wondered at, as, from all we saw and heard of new farm buildings, new or greatly improved cottages, new post-office, new schools, good reading-rooms, good libraries in connection with Mudie's for new publications, to which the working people have access, and the liberal support of a Keele farmers' club, where encouragement is given to every kind of rural and agricultural improvement, it required no great penetration to perceive that there was a practical every-day exemplification of the inscription on the new mansion, "*Suis quam sibi*," and of that still more homely family motto over the doorway, "Thank God for all."—R. FISH.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE decline of the late crops of Peas, Beans, Cauliflowers, &c., should be followed by their immediate removal, and no decaying or useless vegetable matter at this moment should be allowed to cumber the ground. If the vacancies be not directly required they had better be trenched, rough-dug, or ridged for exposure; the distribution of manure to be governed by a due consideration of the late and future crops. For instance: the Onion-quarter has probably received manure sufficient to carry a crop of Cabbage without further assistance. Strong-growing Peas and Beans impoverish the land; quarters which have been thus occupied might be appropriated to early Potatoes in due season. *Cauliflowers*, to prevent the destructive attacks of slugs on the young plants of these and of Lettuces mix soot and lime together in equal portions, and dust them over with it once or twice weekly. The Lettuces that are just coming into use should be lifted with balls and placed in frames. *Cabbages*, make good the blanks that may have occurred in the plantations of these and of Coleworts, and keep a large reserve to make plantations in spring, as well as to make good the blanks caused by the winter. *Onions*, look over the bulbs that have been stored, and remove any that are beginning to decay. *Potatoes*, see that the disease is not making its appearance amongst them, but if it has let them be picked over without loss of time. *Turnips*, thin the late sowing; but it is not necessary to leave them at so great a distance apart as the spring and early summer sowings.

FLOWER GARDEN.

As we have lately experienced a few cold frosty mornings the more tender kinds of plants, which are to be saved, should be taken up at once. Variegated Geraniums will not bear much frost; and where the plants have to be wintered in situations which are not very suitable for them, they should be taken up before they are injured, as they will be much more liable to damp off and die back in winter if the wood be injured by frost; to be kept over the winter just as they are lifted from the beds, and to be cut back early in spring after starting them into growth, when the cuttings will root freely in heat, and will make useful-sized plants by planting-out time. Proceed, therefore, with potting such plants with as much dispatch as possible, and if practicable a little artificial heat should be applied to help them to root before winter. The earliest opportunity may now be taken of removing all such plants as Auriculas, Carnations, Pansies, &c., that are growing in pots, and that have been temporarily protected from the rains, to their winter quarters: a cold dry frame, where provision is made for a circulation of air beneath and amongst the plants, is one of the very best situations for the purpose. But very little water to be given to these plants during the winter, as they only require just sufficient to prevent their tissues from drying up and shrivelling, and the drier they can be kept without this taking place the safer will they be from injury by frost, and the more healthy and vigorous to produce good blooms in the proper season. They should have air admitted to the frame daily, unless the weather is very severe and boisterous. They will require a moderate degree of protection in the most severe part of the winter; but otherwise the protection of the frame and sashes will be sufficient. Unless when alterations are in hand the principal work in this department for the present will be mowing and clearing, and if anything like neatness is to be maintained, sweeping up of leaves will soon require daily attention; also see to getting the gravel walks thoroughly cleared of weeds and moss; roll them frequently when wet to keep the surface hard and smooth.

FRUIT GARDEN.

The principal routine here will consist in gathering and storing all the late varieties of Apples and Pears. The present is by far the best time for lifting and transplanting very vigorous unfruitful trees on the walls. Apricots, Peaches, and Nectarines may be so treated with great advantage, and after the operation is completed they should be well mulched-up for the winter. Fill up all vacancies on the walls with young trees. Never let this be left until the spring if it can possibly be avoided. Where root-pruning is considered necessary, now is the time to see to it.

GREENHOUSE AND CONSERVATORY.

Begin gradually to diminish the quantity of water, and water the plants in the morning so as to have the houses dry during the day. Do not, however, suppose that growing plants require to be dried-off during the dormant season: what they want is sufficient to prevent their drooping, saturation, of course, being avoided. Conservatory and stove creepers trained under the roof will require an additional cutting-in to allow more light to pass to the plants underneath. Such as have done blooming may be well thinned-out at once, and the remaining shoots tied somewhat closer together. Hardenbergias, Kennedyas, and other early spring-flowering climbers should, however, not be disturbed at this season, or it will materially affect their beauty in spring. The present is a good time to procure from the nurseries or from the reserve garden a supply of Rhododendrons, Belgian Azaleas, and Kalmias for forcing; select plants well set with bloom and of the desired size. A portion of the stock of Roses, Lilacs, Honeysuckles, &c., in pots, may soon be placed in a pit to have a slight advance of temperature. The Chinese Primroses to be removed to a shelf in the greenhouse as near the glass as possible, with plenty of air at all favourable opportunities. Herbaceous Calceolarias to be treated in the same manner and duly attended to with water. Cinerarias to be protected from the ravages of green fly by fumigations of tobacco or by syringing with tobacco water.

PITS AND FRAMES.

Regulate the general bedding stock, and get the majority established in small pots. Give as much air as possible, and restrict the supplies of water to mature the growth as far as possible. All temporary pits for their accommodation should be completed by this time, glazing and other repairs must be forthwith finished. Common mats afford scarcely sufficient protection to the half-hardy plants in store-pits. For such purposes a stock of straw or reed mats should be made in wet weather.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

KEPT moving the surface of the ground amongst all growing crops. Find that most of the grubs have done their worst amongst Cabbage plants; made sure to kill every one before he had a chance to reach a second plant. Just moved the ground among such young plants with the point of a fine-tined fork. No vermin in the ground like to have it disturbed about them. Threw some lime and soot over and amongst the foliage of Celery, as grubs, slugs, and worms had begun to mark the leafstalks, which interferes with the look of the vegetable, at least when partly dressed, even if the heart is all sound and untouched. In stiff soils a layer of ashes round the stalks in earthing-up is a good thing, as none of these interlopers care much to pass through it. Fresh sawdust we have also used, but we cannot say we like that for two reasons: it is not good when undecomposed, or uncharred, for mixing with the soil, and if obtained at all from resinous wood it is apt to taint the Celery. Much the same may be said of tan. Next to ashes, the produce of a charred heap, burnt clay, &c., are very good for keeping the stems of the Celery clean. Men used to put in the earth loosely first, then the ashes, &c., round the stem, and squeeze the earth to the ashes, so that no great quantity of ashes is wanted. For those not used to the work two pieces of sheet iron or zinc 1 foot or 15 inches long, 6 inches wide, and rounded so as to resemble half-circular drain-tiles, answer very well. The pieces are placed loosely on each side of the Celery plant, the inside filled with ashes, and the earth applied outside in the usual way, when the iron sheaths are drawn up and taken to another plant, the soil being firmed-up to the ashes. Six of these semicircular pieces, it matters not what they are made of, will do for a row of three plants across a bed.

Piled up into a long heap lots of prunings, thinnings, &c., collected during the summer, covered with weeds, earth, and sawdust, and set fire to it to char part, and burn up the other into ashes, clay being the outside covering. Took the opportunity to do this when our employer was from home a couple of days, as, if the wind set towards the

mansion, it would carry with it something different from the spices of Araby. Such heaps, however firmly you may tread them, emit a great smoke at first, but as the heat draws the contents into little compass, and they are more securely covered, the smoke and the fumes afterwards given off are of less consequence. In opening such heaps when the charring is about done, the men should cover their nose and mouth with a thin handkerchief, and keep their head away from the opening as much as possible. A little carelessness is quite sufficient to make the workers ill. Turned over also a rubbish heap in which waste vegetables, &c., had been placed, adding short grass, brushings of leaves, and similar materials, chiefly at the bottom so as to cause the whole heap to ferment considerably, which has a tendency to destroy vermin and seeds of weeds, whilst the top being covered with earth prevents most of what is valuable in gases from escaping.

Proceeded with routine much as last week, pricking out, planting out, and commenced third piece of bed in the Mushroom-house.

FRUIT GARDEN.

Much the same as last week. Gathering, storing, and preparing for alterations, &c.

ORNAMENTAL GARDEN.

Here, also, the work was much the same, in housing, cleaning, taking cuttings off, and gathering seeds, marking Dahlias, placing a little earth round stems, cutting down the forwardest Hollyhocks, the stems to be charred, &c. the chief work is, what we alluded to last week—preparing for the Calceolaria cuttings. We have just prepared ten lights of a cold pit, which though very shallow has the bottom below the ground level. To guard against too much damp we placed about 9 inches of dry litter over the bottom, such as that from which all the droppings and shorter straw had been shaken clean for Mushroom-beds. This long dry litter, therefore, was used more as a security against the damp rising than for any little heat it would yield. A little shorter and older litter was placed over the long stuff and firmly trodden. Upon that was placed about 3 inches of half-decayed leaf mould, or three-parts decayed leaf mould, mixed with the riddlings of the soil used, with a barrowload of lime previously added, and all well mixed together so as to settle any worms or slugs there might be in the leaf mould, &c. This was also firmly trodden. On this was placed 3 inches of sandy soil also well trodden again, being made of scrapings from the roadside a year old, rather loamy soil from the roadside, with about one-fifth of road-drift—mostly sand from flints ground by wheels of vehicles. This when levelled was covered with about one-quarter of an inch of that sandy road-drift, beaten all over with the back of the spade. The soil being dampish we give no water until the cuttings are inserted, and the one watering will serve them a long time. On Thursday we commenced putting-in the cuttings—say, 1½ inch apart, and in rows less than 2 inches apart. We will not be so successful as usual if we lose 1 per cent. Here the cuttings will remain protected from severe frost until they are given more room in temporary beds in the beginning of March. Some of our Calceolarias are still as fine as they were in the middle of July or the beginning of August, and striking late and keeping cool we consider the main causes of success. Will make arrangements for taking-in some of the tenderer subjects from the flower garden. As for Scarlet Geraniums in general, cuttings struck before the middle of October generally do as well if not better than old plants taken up unless good treatment can be given to them.—R. F.

TRADE CATALOGUES RECEIVED.

John Cranston, King's Acre, Hereford.—*Descriptive Catalogue of Roses*. 1863-1864.

Fairhead & Son, 7, Borough Market, London.—*Catalogue of Dutch Bulbs and Flower Roots*.

William Paul, Waltham Cross.—*Rose Catalogue*. 1863-64. Sutton & Sons, Reading.—*Autumn Catalogue of Bulbous Flower Roots, Geraniums, Fruit Trees, &c.*

Smith & Simons, Argyle Arcade, Glasgow.—*List of Gladioli*. 1863-1864.

COVENT GARDEN MARKET.—OCT. 3.

The market continues well supplied with all kinds of fruit and vegetables, and the demand is good for the season. Grapes, Pines, and all hothouse fruit are quite sufficient for the demand. Pears are abundant, and Ribston Pippins are now brought in larger quantities. Madeira Oranges are coming in, and Lemons are falling in price. The best Cobs are bringing 65s. per 100 lbs. Cape Broccoli is now making its appearance. Of Potatoes the supply is still ample for all demands, and prices have undergone no alteration.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

BERRERY HEDGE (*W. D. Paine*).—The Common Berberry (*Berberis vulgaris*), is the best and only one of the genus suitable for a boundary hedge.

TRAINING VINES (*J. A. P.*).—It is not common to train the Vines down the rafters of a lean-to vinery, though it is common enough in span-roofed houses to train them up one side and down the other. They do very well in that way, but the experience we have of training them down the roof of a lean-to is against such practice. The Vines may be trained down from the back when the angle of the roof is 25°; but if it is a high pitch or even one near 45°, the Vines will not do well. We have tried it and been disappointed. It is the nature of a Vine to grow upwards, and although overluxuriance may be checked by training, yet this mode of training is not to be recommended for Vines in general. We should plant them in a border in front of the house, and move them as you propose in November, but apply no heat until a month before forcing is commenced. As you object to the naked stems, we should graft them, at the time of introducing them into the house, at the point of their entering the house with the kinds you wish, still retaining the old Vines to bear fruit until the grafts were of sufficient size to bear, when the old Vines would be removed.

PIGON DUNG (*W. D.*).—It is one of the richest of all manures; and there must be something very peculiar in your soil if your gardener is correct in saying it is of no use. Even on very light soil if dug in it is very fertilising, and still more so on tenacious loams. Buy our "Manures for the Many," the new edition of which you can have free by post from our office for five postage stamps. Pigeon dung makes an excellent liquid manure.

WORK ON ENGLISH BOTANY (*F. Myatt*).—"Wild Flowers of Great Britain," now publishing at our office in shilling monthly Numbers, contains coloured portraits of the species and full descriptions.

MADEIRA ENTOMOLOGY (*N. A. D.*).—Mr. Van Voorst, Paternoster Row, has published a work on the Insects of Madeira, and if you write to him we have no doubt he will give you satisfactory information. The naturalist of Madeira is the Rev. Mr. Lowe.

WINTERING GERANIUMS (*W. T. E. B.*).—Your boxes are right for planting Geraniums in for wintering. They will do very well in a cellar, but you must cut off all the leaves to prevent their moulding and decaying. We should think the landing on the top of the stairs would keep them very well providing you give them no water unless the leaves flag, and there is no current of air rushing at them. We need not say frost must be excluded, but it is an easy matter to move them to a warmer place to induce growth, and, whatever you do, do not place them in a warm room in severe weather; but keep cool and dry, and so prolong the plants' existence without promoting growth.

CULTURE OF CLIANTHUS DAMPIERI (*Leighton B.*).—It requires a compost of sandy peat half, and turfy loam, with a free admixture of silver sand, free drainage, abundant pot-room—it ought never to become pot-bound; it should have sufficient water to induce free growth, but not a drop more than is necessary, by which we mean that the soil should not be soddened with water nor become dust dry, so dry as to check growth. A warm greenhouse temperature with abundance of air and light suits it exactly. It does better planted out in the border of a greenhouse than in a pot, and rarely does any good after flowering once profusely.

PRESERVING THE ROOTS OF COLLECTED PLANTS (*Flora*).—The best way to keep the roots of the plants you collect during your continental tours is covered with damp sand in a botanist's tin collecting-box.

TANK-HEATING (*T. M., Cheshire*).—The water will flow in the tank without a division, but much better with one. Though it may be done, we do not approve of heating a large greenhouse with pipes from such a tank, as the circulation will be languid. We would advise heating the tank by taking the pipes through it, with a valve or a turncock where it joins the greenhouse, but with the circulation complete in the tank, and only put on the greenhouse when desirable. This will ultimately be the most economical plan, more especially if you cover your tank with wire. We should, however, prefer slate, and if you use cocoa-nut fibre it will let some vapour into it. That fibre is a bad conductor of heat, unless when wet, and then it does well enough. A thick layer of it, and dry, will not let the heat from your tank up.

KITCHEN-GARDEN EDGING (*A. Norrie*).—Bricks laid so as to have one of their angles upwards make an excellent edging. Thus A

HEATING TWO HOUSES FROM ONE BOILER (*J. C., Crediton*).—There will be no difficulty in heating both houses from the same boiler; but the boiler must be sunk so deep that the top may be a foot below the level of the return-pipe in the orchard-house. Then a T-pipe with valves would serve for the flow and return to both houses; or you may have a T return-pipe, and take a single flow into a cistern higher than the flow-pipes in vinery, and from thence take a flow to orchard-house and vinery, to be used or not as you desire. We see nothing to prevent your growing late Muscats as you propose; but we would decidedly alter the slope if we should have an upright wall at the south side and an open drain there. As it is now, all the water that falls on the border will tend to fall to the front of the house, and sooner than that we would have no outside border, but a close-cemented wall and depend entirely on the inside border. If you contemplated early Grapes it would be easy with the position of your border to take a pipe through the bottom of it.

PEARS ON QUINCE STOCKS (*W. Hilder*).—Beurré Superfin, Fondante d'Automne, Louise Bonne de Jersey, Beurré Hardy, Joséphine de Malines, Baronne de Mello, Doyenné Gris, Winter Nelis, Beurré d'Anjou, Beurré Sterckmaus.

ARRANGEMENT OF CUTTINGS OF BEDDING PLANTS (*J. B. C. B.*).—We think it would be taking much trouble without producing any satisfactory results.

SELF-REGISTERING THERMOMETER (*J. Bryan*).—Certainly do not throw it away. Write to Messrs. Negretti & Zambra, they will tell you what to do.

SEEDLING TROPEOLUM (*W. F. S.*).—The bloom is brilliant scarlet, but there are many such, and too much depends upon the habit of the plant for us to give an opinion upon its merits from a single flower.

APRICOT TREES IN POTS (*J. G.*).—We are glad you have succeeded so well with the Cherries. If you plant your Apricots out you will have less trouble in watering; but you will have more trouble in root-pruning than if you kept them in pots. On the whole, well nipped, and root-pruned when necessary, we think they do best planted out.

EVERGREENS FOR A NORTH ASPECT (*A Subscriber*).—*Berberis aquifolium*, *B. empetrifolia*, *B. Darwini*; *Box*, Blotched-leaved, Curled-striped, Gold-edged, and Narrow-leaved; *Eucynimus japonicus*; *Holly*, Gold-blotched Hedgehog, Silver-striped, and Minorca. Put what shrub will thrive "18 inches from the foot of a Yew hedge?" *Periwinkles* might be used for surfacing, of which there are numerous varieties. The roots of the Yew will rob the other plants unless those roots are kept away by a wall or boarding.

GARDEN INFESTED BY INSECTS (*M. S.*).—If you could burn the surface soil conveniently that would be a certain cure, for it would not only kill the mature insects, but their eggs. The soil should be burnt fully 1 foot deep; but if that cannot be done, throw gas-lime over the surface, like salt to kill weeds on walks. Allow this to remain on the surface a fortnight; then dig it in, and keep forking the soil over through the winter. Be cautious about using gas-lime where there are fruit trees, and do not sow or plant anything until six months after the gas-lime is applied. We fear salt would do little good, but liming would do the land no harm. Soot is liked by few insects; a thorough dressing with it helps to clear the soil of insect pests. Guano sprinkled on ant-hills will mostly expel them; but arsenic mixed with honey, or sugar and water, is greedily devoured by them, and, if of course, destroys them. It must be kept out of the way of other animals.

PANSY-CULTURE (*Leighton B.*).—We presume your Good-Gracious Pansy is planted out, and that no cuttings have been taken. Although it is late take cuttings at once, preparing first of all a frame to put them in. Put 6 inches of coarse gravel at the bottom, then a layer of cocoa-nut fibre or some such material, so as to prevent stagnant water lodging. On that place 4 inches of moderately rich loam and about one-fourth of leaf mould, cover the surface with silver sand 1 inch thick, and in this insert the cuttings taken from the tips of the young shoots at such a distance that they stand clear of each other. Give a little water to settle the soil round the cuttings, and shut up close. They will strike in about six weeks, when they must have abundance of air and light, taking off the lights in mild weather. Another plan is to take up the old plants and winter them in a cold frame, from which any quantity of cuttings can be taken in the spring; but they neither make such good plants nor flower so early. Pansies for early flowering should be struck in July, planted in beds or borders in September 9 inches to 1 foot apart. Cuttings struck late do well enough for summer display, and spring-struck cuttings make fine autumn-blooming plants. We prefer potting Pansies into small pots early in autumn and wintering them in a frame, and we shall follow that plan with our Double Pansies and take no end of cuttings from them next spring, and have a fine bloom right through the summer and autumn.

NAME OF PINK (*A. Z.*).—It is a good double hybrid Pink; but we do not know that it has any special name.

POISONING MICE (*An Old Subscriber*).—Wheat boiled gently without burning the grains, in a strong decoction of nux vomica will kill them. This is really the "poisoned wheat" formerly sold, except that strychnine was used, which is the active principle of nux vomica. It poisons fowls as well as mice. Phosphorus pills also poison mice and rats.

WINTERING BEDDING PLANTS (*T. D. G., Warren House*).—The plants will do very well in the pits; but if the greenhouse is empty, and you can also there keep out frost, they will there do better still, as there will be more air and light. Your Pear is the *Burré de Capiaumont*.

NAMES OF FRUIT AND PLANT (*F. E., Pilkington*).—The fruit is that of one of the *Granadillas*, probably either *Passiflora quadrangularis* or *P. alata*; but the materials are not decisive; What are the stipules? Its merit as a dessert fruit is a matter of taste. It is much used in the tropics. The plant is *Celsia sublanata*. (*G. W.*).—1, Margil; 2, Golden Harvey; 3, Old Nonpareil; 4, Scarlet Nonpareil; 5, Gravenstein; 6, Adams' Pearmain. (*E. R., Leyton*).—Swan's Egg. (*G. K., Sevenoaks*).—No. 1 is certainly not Williams' Bon Chrétien, but Louise Bonne of Jersey; 2, Lewis's Incomparable; 3, we cannot make out—it appears to be Winter Nelis; 4, Wadhurst Pippin.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (*C. H.*).—1, *Polypodium vulgare*; 2, *Lastrea Filix-mas cristata*; 3, *Polypodium vulgare cambricum*; 4, *Asplenium trichomanes*. (*Mrs. F. Tyler*).—It is the *Chlora perfoliata*, or Yellow-wort, one of our prettiest English annuals. It is also sometimes called Yellow Centaury. It is not a rare plant. (*H. O.*).—Your plants are—1, *Sedum Sieboldii*; 2, *Campanula fragilis*; 3, *Abutilon striatum*; 4, *Litobrochia vespertilionia*; 5, *Lycopodium Schottii*; 6, *Torenia asiatica*. (*Tyro*).—Of your Ferns No. 1 is *Cyatopteris fragilis*, var. *angustata*; 2, *Asplenium adnatum-nigrum*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

SMALL BIRDS AND THE POULTRY-KEEPER.

WE suppose it is because the small bird controversy has appeared in the "leading journal," that it has assumed so much importance with the public. Yet, if we reflect, all persons are more or less interested in it. Some like the birds and cultivate them; some like their fruit and hate the birds that eat it; some dislike the birds and kill them, not for damage, but because they dislike them. A correspondent writes to say she has been obliged to cover the tops of all her pens with small wire at a considerable cost. She is convinced, after a short time she has more than saved the amount in food—the sparrows and small birds can no longer get it. We have lately constructed a large pen about 20 feet square. We used the smallest wire netting on purpose, but there was one strip about 3 feet by 3 inches, where we were compelled to put some larger-meshed wire. We put it in the most out-of-the-way place, and where we thought it would be most inconvenient for the birds. We went to look at the pen last week, and found it full of sparrows, chaffinches, &c. We were armed with a small net, and thought we could capture some while they were seeking an outlet. Nothing was farther from their minds. They flew through the larger mesh, spite of all our provisions, with as much ease as if there were no wire at all. Since then we have watched closely. We like all sorts of birds, and do not wish to see them destroyed; but we are sure few people are aware of the quantity of food consumed by them. The blackbirds and thrushes never come into the pens, nor do they feed with the fowls. We do not accuse them of any mischief, so far as poultry food. They must fight their own battles with the gardeners. Twice or three times per week we feed entirely on Indian corn, not because we approve it much as food, but because it makes "banyan day" for the small birds.

We have been trying to come to something like a scale for feeding poultry, to be able to answer any one who wishes to know the quantity of food a fowl should consume. We are for the present beaten by the small birds. Their victory is only temporary, and within a few days we shall be able to resume our experiments. We agree with our poultryman, "The sparrow is the greediest and impudentest bird there is." They fly up when we go into the pen and get out of reach; they are down the moment we turn our backs. The point, however, on which we would insist is, that they consume a considerable quantity of food which is put down to the fowls, and which forms an item in the expenditure where everything has to be bought. So long as these visitors can get good corn and meal they will not look for grubs. Amateurs who keep birds in confinement will, therefore, not only lessen their expenses, but they will confer a benefit, either by excluding them from their aviaries, or by adopting Indian corn three days per week during the winter.

THE CAYUGA BLACK DUCK.

ITS HISTORY, ORIGIN, &c.

This bird derives its name from the lake on which it is supposed to have been first discovered. But of its origin, like that of the domestic fowl, little is now known. It is very natural, therefore, to inquire whence so remarkable and valuable a bird was originally obtained; but the conclusion seems to be that it results from the intermixture of the Wild Black Duck (*Anas obscura*), not uncommon in our lakes and rivers. This appears to be the popular opinion at the present time; and if we are limited to any one of the wild breeds of this genus now known to us in our inquiries for the probable ancestor, it is to the Wild Black Duck, in our humble opinion, the honour should be assigned.

This species, as we are informed, has been domesticated in several places, and was quite common some fifty years ago in the barn-yards in the vicinity of Boston, &c. "In the year 1812," says Dr. Bachman, in a note addressed to Mr. Audubon, "I saw in Dutchess county in the State of New York, at the house of a miller, a fine flock of Ducks, to the number of at least thirty, which from their peculiar appearance struck me as different from any I had before seen among the different varieties of the tame Duck. On inquiry, I was informed that three years before a pair of these Ducks had been captured in the mill-pond. They were kept in the poultry-yard, and, it was said, were very easily tamed. One joint of the wing was taken off to prevent their flying away. In the following spring they were suffered to go into the pond, and they returned daily to the house to be fed. They built their nests on the edge of the pond, and reared large broods. The family of the miller used them occasionally as food. They considered them equal in flavour to the common Duck, and were easily reared. The old males were more beautiful than any I have examined since, and as yet domestication has produced no variety in their plumage."

"The young of this species" (the Wild Black Duck), says Audubon, "grow with remarkable rapidity, and, like the Mallard, of which they seem to be only a variety, acquire the full beauty of their spring plumage before the season of reproduction commences. . . . In the early part of autumn the young afford delicious eating, in our opinion very much superior to the famous and more celebrated Canvass-back Duck."

"It is admitted," says a writer, "that our Cayuga Ducks originally sprung from the Wild Black Duck. However altered they may now appear in bulk, colour, or habits, the essential habits remain the same; no disinclination to breed with each other is evinced between them, and the offspring are as prolific as their mutual parents. The general tone of their plumage is closely repeated in all specimens."

For the following interesting account, and the very spirited portraits of the Cayuga Black Ducks figured at the

head of this article, we are indebted to the politeness of Mr. J. R. Page, of Sennet, Cayuga County, who is a successful breeder of them:—

"Of the origin of the Cayuga Duck," says Mr. Page, "I cannot give anything reliable. This Duck has been bred in the county so long, that all positive trace of the origin, so far as I can learn, is lost. Tradition says they are descended from a sort of wild Ducks that stop in Cayuga Lake and Seneca River, on their passage north and south, fall and spring; yet from hunters I have never been able to obtain or hear of any closely resembling them, either in weight or feathers. Yet they are called the 'Big Black Duck,' 'Cayuga,' or 'Lake Duck.' The first I ever heard of them was between twenty and thirty years ago. A farmer near Montezuma, on Seneca River, had a flock of Ducks bred from wild Ducks that he had caught, and they were very large and fine. Another tradition is, that they are a stock brought from one of the Hudson River counties" (probably those mentioned by Dr. Bachman), "but the general belief is as above, that they originated from a wild stock."

"The Black Cayuga Duck in perfection, is black with a white collar or neck, or white flecks on neck and breast—rarely black without white, and as the white seems inclined to increase, we usually select them nearly or quite black for breeding. The Duck has a faint green tint on head, neck, and wings. The drakes usually show more white markings than Ducks, and the green tint on head and neck is more strongly marked. They differ from the East Indian and Buenos Ayrean Ducks very materially, are much larger, longer in body, and shorter in leg, better feeders, but are not so intense in colour; indeed, beside the East Indian (and I have the latter), the Cayuga looks brown."

"The plumage of the Cayuga Duck," says another writer, "is of great richness, much resembles the Wild Duck; the drake's especially is magnificent, its head and neck being a rich lustrous green, with a white ring at the base of the neck, breast of a reddish-brown, the remainder of the body and wings partaking very greatly of the Wild Mallard."

CHARACTERISTICS.—"When well fed," continues Mr. Page, "the Duck begins to lay about the 1st of April, and usually gives an egg every day until she has laid eighty or ninety, when she will make her nest and sit if allowed; if not, will generally lay a litter in September."

"The Cayuga Duck is hardy, good size, and for the table is superior to all other Ducks or poultry of any sort; flesh quite dark and high-flavoured. If well fed they become very fat; they can be readily made so fat that they cannot step over a broomstick; they cannot raise themselves from the ground by their wings, a foot-wide board keeping my Ducks from my little trout-pond. My flock last year weighed—Ducks, one to three years old, 7 lbs. to 7½ lbs. each; Drakes, 9 lbs.; Ducks, 8 lbs., or 17 lbs. the pair; yet these are extreme weights, and only reached by careful feeding, and in very small flocks; 12 lbs. to 14 lbs. the pair would be a good average in large flocks. I once had a small flock that averaged at six months 16 lbs. the pair, but they had been forced to their utmost, and never gained weight after six months."

Another writer says—"the Cayuga Duck is very quiet in its habits, cannot fly, rarely able to rise from the ground; a fence 1 foot high will turn them; not disposed to wander from home; commence laying about the last of March; lay fifty to ninety eggs, when they wish to sit if everything is convenient; sit well; careless mothers; cross readily with other Ducks, and produce is certain."

"One of my Ducks," continues Mr. Page, "showed a disposition to nest early this year; sat on fourteen eggs; hatched thirteen young, and bids fair to raise all of them, as they are now (July) several weeks old, yet the Duck and young ones are more often seen apart than together."—C. N. BEMENT.—(*Albany Country Gentleman*.)

LOST FOWLS AT WAKEFIELD SHOW.

In reply to Mr. William Lawrenson's letter respecting his pen of Bantams at Wakefield, I at once advised him of the loss, and also advertised them in your Journal, and wished him to charge a reasonable price for them. He at once replied that he would have the full amount, or he would sue the Committee, and write a letter to your Journal, if his

claim were not paid. I thought we had a right to pay him, and having but £4 in my office at the time I received his letter, I sent it to him on account, and said I would bring his case before the next Committee-meeting. I did so, and was advised by one of the Committee to ask him to take the claiming price, less 10 per cent., as per rule of the Society, and allow us for the hamper I returned. He refused to comply, but wrote to Mr. Wainwright, and he brought the letter before the Committee, and they thought Mr. Lawrenson was too hard with them not to take the claiming price. Mr. Wainwright was requested by the Committee to inform Mr. Lawrenson that Mr. Crosland had met his case in a very manly way, and they trusted he would be satisfied with the £4. I am yet out of pocket the money I paid, as several of the Committee think we had no right to pay.

Mr. William Lawrenson ought to have the management of an out-door show. It would put him about to keep an eye on all. I engaged three men to feed and water the fowls, and the birds were all right at four o'clock, and then a very heavy storm of wind and rain came on. I quite expected all the Pigeons to be flying into the air, and they would have done so had I not placed boards on the top of the pens to keep them dry; but I am glad to say I got them all hampered. Several Bantam and other pens were blown partly off the platform, and were penned wrong. This took place at the time I was penning the Pigeons. The men engaged informed me that one of the Duckwing Bantams had been out. It was only the end pens, and they were Black Reds. I wonder if Mr. Lawrenson could have made the wind and rain obey his commands; if he could he would have been worth £50 to us on that day. As soon as the rain came on all the exhibitors commenced to pen their own birds, and the only fowls left for us to pen were those that came by rail.

Mr. Lawrenson ought to attend a few Yorkshire shows, then he would form an idea what the Committee has to do with out-door shows. It is impossible to prevent parties penning their own birds. If Mr. Lawrenson was Secretary, as I was, to take down the amounts and pay all the prizetakers on the ground, as I had to do, he would have plenty of time to look after penning the birds. After all we had but two mistakes, and we wish to do as nearly right as we can. I have had no other complaints. I sent all the birds off from the Wakefield Station the same night, and all the prizes were paid within three days of the Show, and I doubt if any one could act in a more straightforward manner than I have done. After hearing my reply I think your readers will not find much fault with the Wakefield Committee, and I can safely say we are out of pocket above £100. Mr. Lawrenson can have my post next year, as I intend to give it up.—JOHN CROSLAND, JUN.

[With this reply from Mr. Crosland the controversy must cease from our pages. It is very evident that the Wakefield Committee left all the labour for Mr. Crosland, and so far did not do their duty. It is quite equitable that 10 per cent. should be deducted from the price affixed to the pen by Mr. Lawrenson; and under the circumstance of the Show causing a heavy loss to the Committee, we think Mr. Lawrenson would only do as he would wish to be done by, if he accepted the £4 in full of all demands.—Eds.]

OSWESTRY POULTRY EXHIBITION.

ALTHOUGH the just-closed Meeting is the first ever held by this Society, in the hope of directing poultry-keepers to the most remunerative breeds for market purposes, and to also bring into local notice other kinds of the more strictly fancy-feathered varieties, it must not for a moment be conceived that the district around Oswestry is not deservedly renowned for its market fowls. On the contrary, for a long succession of years, even prior to the institution at all of poultry shows elsewhere, Oswestry market has supplied an amount of live poultry to various districts in quantities weekly that if here stated would to many of our readers appear altogether fabulous. On the Wednesday, which is the market day, consequently are numerous dealers to be regularly seen plying earnestly their avocation; and on visiting the railway station at the conclusion of the market, few strangers would be prepared to see the many railway truckloads exclusively of poultry thus being forwarded to

Birmingham, Birkenhead, Chester, Liverpool, Manchester, Wolverhampton, and other places. When it is called to mind that this supply seems but little shortened week after week the year through, all reflective persons will admit that to guide such wholesale producers to the most remunerative breeds is a step in the right direction, and such as will make ample returns for the amount of outlay and personal trouble that may attend it at the outset.

A few years to come will, doubtless, find many agriculturists around Oswestry who now consider "a fowl only a fowl whatever it may be," as having arrived at the more just conclusion, that each head of poultry they rear is of precisely the marketable value it will realise when sold; and that some "old stagers" who kept the "same fowls their fathers did before them, as doing well enough for anything," will find to again return to the principle just laid down would curtail their revenue by at least two-thirds of what, with care and management, may be then insured. It is at once candidly admitted that some few of our best breeds of poultry may not suit the neighbourhood, although, perhaps, as yet, never fairly tested. For instance: not a single Black Spanish fowl was exhibited at Oswestry—an incident that we cannot call to recollection as ever taking place at any poultry show before; but on inquiries on the ground, we find that the local breeders seem never to have seen them, although conversant with them by name. Now, for egg-production (and the sale of eggs never fails—at good prices too), it is well proved that Spanish fowls if not too highly bred are equal, if not superior, to most varieties.

As attention has at length been arrested to improved poultry-culture in this neighbourhood, a few years to come will bear conclusive evidence that the institution of a poultry show at Oswestry was a public good. One or two hints to the Committee of Management may not here be ill-placed. It would be wisdom on future occasions not to "restrict entries to sixteen miles round." This prevents local breeders from seeing what can be done elsewhere, and acts somewhat as a prohibition to their own individual advancement. Even, by way of argument, if the prizes for one year should go almost wholly elsewhere than locally, this fact is certain to produce an amount of emulation to hold their own that will infallibly bring improvements homeward on future occasions, and do everything necessary to remove their present apathy in local poultry-management. The trial will not only insure this success, which is a most important one, but it will also as undoubtedly triple the interest and numbers of visitors to future shows at Oswestry. The pens on this occasion were placed some 12 inches too high for easy inspection—a fault that will in time to come be easily rectified. Again, the time specified for the birds to be at the Show should be strictly enforced; to do so is only justice to those parties who send at the hour stated in the prize-schedule. If this rule is at all broken, one step only leads to increased delays, and it must be remembered punctuality is the very essence of the contract, and empty pens the greatest bane of any poultry exhibition. On the late occasion, by far the best Game fowls, and Geese also, came "too late for competition." As a first Show, these little contingencies must ever be expected, and as the Meeting was only in contemplation about a fortnight before being held, it was quite as well kept as could be fairly expected. We regret to say that unfavourable and heavy showers prevailed almost hourly.

The *Dorkings* were good, the entries of Greys being numerous; and the White ones were so perfect as to appear on the prize list, though the competition was undivided. Mr. Peplow Cartwright's Partridge *Cochins* were very excellent. Many capital *Game* fowls were present, but non-attention to matching the colour of legs was an almost general fault, and in some instances very good birds of quite different varieties were also penned together! Practice will prevent these mistakes in future. Another rather extraordinary feature of this Show was inattention to the number of birds sent together—in several pens one being short of the three birds required by rules; in others as many as even six were forwarded to a single entry. This rule of numbers can never be broken without loss of position in prizetaking. A goodly number of *Bantams* were shown of no particular value, save a pen of the almost extinct Booted *Bantams*. These were small, nicely speckled ones, such as would remind any amateur of long standing of his boyhood-days,

when such varieties were in high esteem, both for their extreme hardihood and good laying properties.

Some peculiarly good White Call *Ducks* were exhibited. *Turkeys* and *Geese* were quite in force and of good quality.

DORKING (Any colour).—First and Second, Lady F. Lloyd. Third, Hon. Mrs. Kenyon. Highly Commended, Hon. Mrs. Kenyon; E. Shaw, Oswestry. Commended, E. Shaw.

COCHIN-CHINA (Any colour).—First and Second, P. Cartwright, Oswestry. Third, Lady F. Lloyd. Commended, G. Williams, Oswestry; P. Cartwright.

GAME (Any colour).—First, T. Jones. Second, H. Crutchlow, Oswestry. Third, E. Evans, Hengoed.

BANTAMS (Any colour).—First, Mrs. Davies, Oswestry. Second, Mrs. Lloyd, Aston Hall. Third, G. Williams, Lloran House.

HAMBURG (Gold and Silver-pencilled or Spangled).—First, C. Cooke, Bradenheath (Silver-spangled). Second, T. Jones (Golden-pencilled). Third, G. Williams, Lloran House. Commended, A. E. Evans, Llanrhadr.

FARMYARD CROSS.—First, Cap. Mansfield, Criggion (Brahmas). Second, E. Hughes, Oswestry (Grey Dorkings and Cochins). Third, J. Groom, Hirlad (Crossed Dorkings).

TURKEYS (Any Colour).—First, W. Minnett, Trefarclawdd. Second, R. Legh, Foxhall. Third, S. Lawrence, Llyncllys. Commended, Mrs. Lloyd, Aston Hall.

GESE (Any colour).—First, G. D. Brittain, Sutton. Second, J. Hamer, Glamafon. Third, R. Peate, Pentreclawdd. Highly Commended, Mrs. Lloyd, Wynnstay Arms; J. Thomas, The Newnes.

DUCKS (Aylesbury).—First, E. Shaw, Plaswilmot. Second, W. Minnett, Trefarclawdd. Third, Mrs. Lloyd, Wynnstay Arms.

DUCKS (Any other Breed).—First and Third, G. Williams, Lloran House. Second, W. Hughes, Pentreshannel. Highly Commended, R. Morris, Knockin. Commended, H. Jones, Trefonen Hall.

Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, officiated as the Judge.

DAY'S GAME PASTE.

For the last five or six years I have been keeping poultry, and for the first and second years had no disease. Since then every year I have lost at least half of my chickens by the "Gapes." I tried various things which I was told were certain cures, but all to no avail; for want of space I could not change my yard. This year I had a brood of Black Spanish chickens which I prized much, being of Mr. Rodbard's strain. Like all the others, when about six weeks old they commenced coughing and gaping slightly. About this time I noticed advertised in your columns "John Day's Celebrated Game Paste;" I procured a canister, and followed the directions carefully, and to my great pleasure, in a week to ten days my chickens were quite recovered. A friend of mine who was losing nearly all his chickens, has since tried it with the same good success. I certainly will never be without some, it being in my opinion invaluable to poultry-breeders who cannot change their fowl-houses and yards every other year.—THOMAS ACE, Ystalyfera Iron Works, Swansea.

APIARIAN NOTES.

(Concluded from page 244.)

No. 8. *Frame-hive*.—Ligurian queen. Bees the best as to colour I had. In March populous. Large quantity of brood and very dry. Bees refused to work in super, though clustered thickly in it. A swarm went off and was lost; with it, of course, the valuable queen raised last year. Side frames of sealed honey of about 8 lbs. taken since.

No. 9. *Flat-topped Straw Hive*.—Old stock of common bees. Enormously heavy in March, though not fed at all through the winter. Moderately strong in bees. Supersed seasonably, but bees refused to work. If no swarm went off and was lost it shows a poor state of affairs within, as the bees are not numerous. A little work was made towards the close of the honey-harvest, and honey taken of about 8 lbs. weight.

No. 10. *Frame-hive*.—Ligurian. My original queen. A magnificent colony. In March very populous; great quantity of brood; a little food, and very wet. A thirteen-inch-square, shallow super made to hold the bars belonging to the frames in the stock-boxes was first put on. This was at different times raised by three other boxes, and the result was 54 lbs. of super-excellent honeycomb. The hive was inspected on August 10th, and two frames of sealed honeycomb and brood removed for an artificial swarm. Seven out of ten of the frames contained brood. I like these shallow supers, putting on one first; then as soon as the combs begin to approximate the glass window, drawing a wire below, raise the first and slip a second between, generally without bars or top. Thus the combs are extended downwards. This may be repeated as the boxes become pretty

full; but discretion must be used so as not to give too much space, or empty comb will be the only result.

No. 11. *A. Stewarton Octagon*.—Common bees. A swarm from No. 5 on July 4th. Had nearly filled its box (14 inches by 10 deep) with comb and sealed honey by the 17th of the month. Is quite heavy.

No. 12. *Common Straw Hive*.—A swarm from No. 6 on July 11th. Very large, more than filling the butt. A hole cut in the top, and a small super with a little comb put on. In six days the hive had reached a considerable weight. The super has been removed with a few pounds of honey, mostly unsealed.

No. 13. *Frame-hive*.—Ligurian-hybridised queen. Early in the summer some broodcombs were removed. The remainder with bees were shifted into a bar-hive and given away to a friend. Present state unknown.

No. 14. *Frame-hive*.—Ligurian. Artificial swarm of last year. In March was found to be rather weak, with little food, a small number of eggs, but no brood; quite dry, but suffering from dysentery. Some combs of brood with the bees clustering therein were given from Nos. 13 and 20. Bees united without the least fighting, and from that time this hive went ahead. On the 23rd of April it was carried out to my country apiary three miles off by my man under his arm. On the 30th of May the hive appeared full of honey wherever the comb was visible. An octagon super was given, and on the 25th of June a second was shipped under the first, which appeared nearly full. On the 6th of July a third super was put on the top of the whole tier of boxes, this last being partially filled with empty combs. Nett weight of honey taken was over 50 lbs.

No. 15. *Frame-hive*.—Common bees. An artificial stock made on the 29th of August. Having driven out the bees from two stocks belonging to Mr. Veitch, the well-known horticulturist of the Exeter Nurseries, I fitted up a ten-frame-box with combs, of which strong stocks had already been deprived. The bees were knocked out on the top of the bars and quickly descended. A little fighting ensued; but their differences were very soon concluded, and this bids fair to be as good a stock as any in my possession.

No. 16. *Frame-hive*.—Hybridised Ligurian. Bees of poor colour. In March was moderately strong with brood and food; quite dry. Destroyed the queen and added the bees and brood to No. 22.

No. 17. *Frame-hive*.—Common bees. Though not fed during the previous wretched summer, this hive in March was found to be nearly full of sealed honey, except where breeding was going on; and it soon became the strongest hive in my whole apiary. Great things were expected from it, and supers were early supplied. The bees utterly refused to work, and a magnificent swarm was lost. A second swarm was secured and united to No. 2 as before mentioned. About 15 lbs. of honey have been removed in surplus side frames.

No. 19. *Frame-hive*.—Ligurian. Artificial swarm of last year. In March not very strong; a little brood and food; dry. This hive gradually increased in strength. An artificial swarm (No. 1 as before mentioned) was made on June 1st. The prosperity of this hive was, in consequence, checked; and it has afforded nothing except broodcomb for another artificial swarm.

No. 20. *Frame-hive*.—Ligurian, hybridised. In March very populous, with plenty of brood and honey. A large super was put on in which the bees worked well. On examination on the 15th of June a great deal of brood was found in the super. This was removed and given to artificial swarm No. 1. A stop was put to all work in the super, and eventually a fine swarm issued and was lost. About 15 lbs. of honey taken in the super and from side frames.

No. 21. *Frame-hive*.—Artificially raised Ligurian queen from best brood of last year. Breeder of quite dark bees. In March was very strong, with large quantity of brood; very damp. May 24th, super put on, to which the bees did not take very well, only making a little comb. On the 20th of June the super was removed, and the frames with the bees transferred into a mammoth-box capable of holding eighteen frames. The bees worked and bred through the greater part of this immense hive, and have been excessively populous. About 25 lbs. of honey have been removed in surplus side frames. It is evident that hives of such dimensions are unprofitable. Notwithstanding its large size a stock in the same box last summer, after working sixteen combs, nearly all of which were more or less bred in, threw out a large swarm.

No. 22.—Originally in a frame-hive. Ligurian hybridised, artificially raised last year. In March was weak with but little brood or honey. The bees and brood of No. 6 were added.

On the 10th of May the bars were removed from the frames and the combs fitted into a set of octagonal boxes, which were hung suspended to a "Salter's" scale, the weights being registered from day to day. I will not now give the results of the register, but defer for a future opportunity. Honey taken, 10 lbs.

No. 23. *Frame-hive*.—Ligurian. Artificial swarm late in 1862. In March not strong, but having a large quantity of brood with pretty much sealed honey, or rather artificial food. Quite dry. This was shifted into an experimental hive, and has not turned out very satisfactory. Only a very small quantity of honey taken. The bees and combs have lately been shifted into a proper-sized frame-hive, and with manifest advantage. A fine artificial swarm was made on the 29th of July, forming No. 25.

No. 24. *Frame-hive*.—Hybridised Ligurian. A splendid yellow queen—breeder of dark bees. In March very populous, immense quantity of brood, and a great deal of honey sealed. Not particularly damp; but a dreadful mortality from dysentery, which continued many weeks. The great breeding powers of the queen seemed to keep up the population, notwithstanding the ground being daily covered with dead bees. There was also constant fighting going on. On the 24th of May I resolved to break up this fine stock. Bees and some brood given to No. 6. Rest of brood to other hives. The queen was sent away to a gentleman who required one for a queenless stock.

No. 25. *Frame-hive*.—Ligurian. Artificial swarm commenced on the 27th of July. An unimpregnated Ligurian queen, rather dark, having been given to me by Mr. Woodbury, I proceeded to raise a nucleus by removing a broodcomb, having only young bees about emerging from their cells. The queen was secured in a perforated zinc box, and the nucleus brought within doors and kept tied up for two days. On the 29th No. 23 was removed from its place, and a very fine swarm of bees entered the nucleus. The queen was liberated on the 31st, and was all right two days afterwards. Inspected again on the 10th of August. No queen nor eggs to be found. Gave a suitable broodcomb from No. 10, original Ligurian queen, and three royal cells were in due time made and sealed. On the 20th Mr. Woodbury having made the singular discovery of two queens being at liberty at once within the same hive, presented me with the young one. She was a very fine queen as to size, and seemed by no means despicable as to colour, and I prized her accordingly. As the nucleus had been for a long time without a queen, I resolved to run the risk of introducing her at once among the bees. Having daubed her wings with a little honey in accordance with Mr. Woodbury's suggestions, she was let out among the bees on the broodcomb, and was at once densely surrounded by them. Being now called away I was obliged to leave her, though fearing an unfortunate result to the experiment, as the bees appeared to be hostile towards her. The next day I had the satisfaction of finding her alive and very active—so much so, that she took flight from the comb in my hand, and made her way back among the other combs. She had already torn out the occupants of the royal cells.

To-day (September the 7th) I have again inspected the hive. A large space of one of the combs is filled with brood and eggs. The queen is a superb one, both as to colour and size—by far the best in my possession. It still remains to be seen whether her progeny be true, an event devoutly wished for by—S. BEVAN Fox, Exeter.

INTERNAL MOISTURE—CONSUMPTION OF FOOD IN UNITED HIVES.

I AM feeding all my hives, and wish to know how it is that those which contain comb and honey accumulate scarcely any moisture on the glass of the feeder; whereas the hives which contain only bees from cottagers' driven hives (several joined together), and such comb as they have made in three weeks gather so much moisture on the glass of the feeder that it requires constantly drying. If this moisture run into the food will it injure the bees? and should I keep a glass on these hives during the winter? Some are wood, some straw, all are doing well; but I cannot persuade the cottagers to save their bees and add them to their other hives. They think they will eat so much more honey during the winter.—A. B.

[The deprived bees either are or have been building combs, which raises the temperature of the interior of their hives very much, and this increase of temperature, in obedience to a well-known law, causes the condensation of an unusual amount of moisture on the glass. Its presence in their food

will do the bees no injury; but a moderate degree of ventilation will probably be advantageous. It is a well-established fact that the bees of three or four stocks when united in one hive consume very little, if any, more food during winter than each one would have done if left separate.]

TWO QUEENS IN A HIVE—QUEEN'S DURATION OF LIFE.

I FEAR I must apologise to Mr. Woodbury for my seeming inattention in not sooner answering the queries he proposed to me some weeks ago. The fact is, that like him I have been pleasure-seeking, though not to the sea-side to encounter any such discomforts as he alludes to; but away among the everlasting cloud-capped hills—the placid lakes and wooded vales of one of the sweetest spots in Britain's isle. To the hills, too, my bees betook themselves—they after their pleasures, I after mine—they to collect, as best they could, in this our fickle climate, the nectared treasures of the purpled heath; and I to inhale its balmy perfumes, climb the alpine steeps, and amidst the quietudes and solitary grandeur of nature, to enjoy for a short season the calm delights of country life. Having now returned, therefore, to home and to duty, I take up *THE JOURNAL OF HORTICULTURE* and re-read some of the more recent communications on apiarian matters. And first with respect to the queries already referred to.

The first problem I am asked to solve is the fact of two queens being found in a hive at the same time. Before giving an opinion of this case I could have wished to be in possession of the particulars before promised by Mr. Woodbury. It is always difficult, in the absence of knowledge of full particulars and circumstances, to do more than merely guess a solution. I believe I may safely enunciate this truth without fear of contradiction, that only one prolific queen will be tolerated at a time in any hive; and that, as a general rule, more than one unprolific queen, or a prolific and an unprolific queen, can remain but for a short period in the same hive. These are axioms which experience and observation will homologate and confirm. The question then is, Under what circumstances are two queens found in a hive? for it will be seen that I have assented to this as a fact. My experience is to the following effect:—

1st. More than one unprolific queen may be found in a hive in certain contingencies, such as during unfavourable weather, prior to after-swarming.

2nd. A reigning prolific queen and a virgin queen may co-exist for a short time under similar circumstances before first swarming.

3rd. A superannuated queen may exist simultaneously with her successor for a brief period; but I must guard my belief by the confession, that in such circumstances my experience does not warrant me in asserting this as a fact; as in such a case I have found the reigning queen disappear from the stage before her successor entered. I may here refer to an article by me inserted in No. 77, New Series, of this Journal, showing the wonderful instinctive foresight manifested by the bees under such circumstances in thus providing against the impending loss of their infirm sovereign.

The second query refers to the longevity of the queen bee. The queens which I had the pleasure of transmitting to Mr. Woodbury were somewhat above two years and three years old respectively; but this, as will be at once perceived, can by no means settle the question as to the longevity of the queen bee. On this subject I have much curious information; but it would require more space than I intend occupying at present to enlarge upon it.

The natural life and the real life of the queen bee have, if I may so express myself, no congruity the one with the other; for my experience shows that her existence may extend sometimes, though rarely, to nearly five years, or it may be cut short in less than as many months. Her condition, circumstances, and the ever-varying contingencies to which she is exposed, often determine her fate long before what may be termed her natural life. I never had a queen under the most favourable circumstances that lived much beyond four years, except one whose age was four years and ten months. The queen of a peculiarly-coloured grey colony of bees, to which I have had occasion more than once to

refer in the columns of this Journal, and whose brilliant golden appearance enabled me easily to follow her throughout her whole career, lived, or I should rather say reigned, for three years and four months; at the end of which period, being stricken with many infirmities, her subjects rose up in revolt against her, and she was accordingly dethroned.

In regard to the foul-brood question I may have to say something by-and-by. Meantime I must cordially concur with Mr. Woodbury in not being contented with the mere "ipse dixit" of any one on the subject, even though that proceeds from what he calls "the great centre of bee knowledge." A verdict without assigning reasons in such a case I look upon as valueless. We have all heard of the old sayings, "Least said is soonest mended," "*Vir sapit qui pauca loquitur*."

"A STEWARTON APIARIAN" must be told, however, that it is he that is "quite at sea" in supposing that I treated the subject of foul brood at all upon the principles he asserts. I think my language is so plain, that "he who runs may read." I shall, perhaps, have a few words on "an experimental apiary" in the next or following Number.—J. Lowe.

TWO QUEENS IN ONE HIVE—MISHAPS IN UNITING ENGLISH AND ITALIAN BEES.

I REGRET to have to announce the death of the junior of the two queens whose inexplicable presence in one hive during autumn was described by me in page 157. I presented her at the time to my friend Mr. S. Bevan Fox, by whom she was placed at the head of a small colony, in which she commenced egg-laying, and proved herself amazingly prolific, thus completely negating Colonel Newman's hypothesis as to her being either diseased or barren. Unfortunately Mr. Fox found it necessary to add to the number of her subjects, and although the operation was performed with the utmost precaution, a terrible fight was the consequence, which also resulted in the death of the poor queen herself. Being a pure Ligurian her demise is much to be regretted; and, curiously enough, I met with a similar misfortune brought about in exactly the same manner almost on the same day. These fatal occurrences prove the danger of uniting bees of different species even when the operation is attended with every precaution that has been suggested by the experience of others as well as by that of—A DEVONSHIRE BEE-KEEPER.

VIRGIN QUEENS.

I SHALL feel obliged by having the opinions of the writers on bee-keeping in *THE JOURNAL OF HORTICULTURE* on the following cases which have occurred in my apiary.

I made an artificial Ligurian-hive on the 23rd of July by taking two bar-frames of brood out of my Ligurian-hive, and putting in a swarm of common bees with the combs, depriving them of their own queen. I examined it on the 28th of July, and found seven queen-cells in process of construction; looked again on the 7th of August, and saw only two queen-cells sealed up; and again on the 12th of August, and saw a beautifully-marked Ligurian queen. On the 25th of August she was laying eggs in worker-cells, also in drone-cells. I examined her again on the 8th of September, and found what I partly expected from the former examination—that they were all drones; and on the 14th the first-laid drones were just coming out of the cells, and drone-brood was still in all stages. Can any one inform me if there is any chance of this queen laying worker eggs?

Another case is the following. When the old Ligurian lost its second swarm on July 16th I took out two combs of brood having five queen-cells sealed up, and gave it a swarm of common bees to hatch the queen. This hive was taken to the heather on the 7th of August; and we examined it on the 29th of August, and found there were only drone eggs but no queen. It will be remembered by those who take an interest in bees that I noticed a similar case last year in one of my artificial swarms; but I would not assert positively that there was no queen present, as the hive was always strong in bees, having supplied it frequently with combs of young brood, and therefore might not have seen the queen in my examination. But in this

case there is no doubt whatever. There are not more than five hundred bees in the hive. We removed every bar and comb into another hive. We did this three times, and there were other two persons along with me at the time without any covering on their faces, so that we are perfectly certain that there was no bee in the hive which had the slightest difference from a worker bee, as we examined every one carefully. Had we seen one I would have retained it and sent it to Mr. Woodbury for microscopic investigation. In some of the cells there were four and five eggs, apparently just laid that day.

I have here, then, a case of a queen which can lay drone eggs only—has she had any matrimonial engagement? and another case of bees with no apparent difference from workers, laying drone eggs also—have they had any “matrimonial engagement?” I am informed that naturalists maintain that to be impossible. If that be true, and worker bees can lay drone eggs, what is to prevent an unmated queen from doing the same?

I cannot say that I believe in the doctrine of parthenogenesis. If it be true it must lead us to believe in many strange circumstances; but to me these two cases which I have attempted to describe go far to prove the truth of parthenogenesis; and I would like very well to hear the opinions of those who are opposed to and those who hold that theory.—ALEX. SHEARER, *Yester Garden*.

[Parthenogenesis is a subject more suited to a physiological periodical than to our columns, and when touched upon must be handled circumspectly, for our Journal is read in the drawing-room as well as the study.—EDS.]

PARTHENOGENESIS—AGE OF QUEENS— HONEY SEASON.

I SCARCELY know whether it is worth while to prolong a discussion respecting parthenogenesis; but I have read the letters in Nos. 25 and 30 as directed, and still think it possible that there may be yet found out some other way of accounting for a live drone proceeding from a virgin queen than has been dreamt of in our philosophy. It may be my want of scientific knowledge that keeps me sceptical. I agree, however, that parthenogenesis is nearly proved. I believe that a virgin queen may lay eggs, and that somehow or other those eggs may produce drones; but I doubt if you were to place her in fresh-made comb, or rather in a hive without any, and with young workers, whether a single egg she lays would vivify.

Alas! I am not so near a convert to the opinion of “A LANARKSHIRE BEE-KEEPER” as to the age of a queen. Surely there are many reasons why my opinion may be the right one, and I have the chance in my favour that “A LANARKSHIRE BEE-KEEPER” may have mistaken one queen for another, particularly if it can be proved that young queens and the old one exist a few days together at liberty in a hive. I cry his mercy therefore, and beg to differ from him. I rejoice to hear his bees have done so well on the moors. I sent mine to a moor near Farnborough; but they have not done so well as last year. I have no heather to speak of within many miles of my present abode.

In reply to Col. Newman, I may state that in 1857 one of the best honey-gatherings I ever knew took place in the latter days of August or first in September when I was living in the Isle of Axholme. There were a few patches of heather two miles off, and heather honey was stored inasmuch as you could “nose it” in front of the hives; but the bulk of the honey then gathered must have been from other sources, as the moor the heather grew on was small in extent and only partially covered with heath. Trees were not plentiful in my part of the Isle, and the only flowers I knew of, excepting on weeds, were those of the second crop of red clover. We all know, as a rule, bees do not like working on red clover. They will at times, however, and did on that occasion.—A HAMPSHIRE BEE-KEEPER.

WASPS.

ARE there drone wasps? Are they very large, and driven out of the nests in the same way as drone bees? Last year what were supposed to be queen wasps were more nu-

merous in the autumn than the ordinary-sized wasps; and this year again, though there are so few wasps, the large ones are beginning to appear in greater numbers than the smaller ones.—E. F.

[Drone or male wasps are both large and small, the latter being probably bred in cells usually appropriated to neuters. They are armed with stings; and the large males, being bred in similar cells to those in which queens are reared, are much about the same size, but may be distinguished by the greater length of their antennae. Unlike drone bees they take part in the labours of the nest from which they are not expelled, but survive until the autumnal frosts destroy the whole community with the exception of the queens (of which many exist in each nest), which alone survive the winter to found fresh colonies in the spring. Including hornets, there are seven varieties of wasps indigenous to this country. The different species vary much in size.]

OUR LETTER BOX.

BILL OF ROUEN DRAKE (*R. M. S.*).—The bill of a Rouen drake should be yellow with a green shade on it. Any other colour is a disqualification. It should be exactly the colour of the Wild Mallard's bill, and that is never black.

MIDDLEWICH POULTRY SHOW.—Mr. Jessop, we are informed, had the second prize for Black Ducks, and Mr. Dixon had the first prize.

DESTROYING VITALITY IN EGGS (*J. H.*).—The eggs of your prize fowls which you wish to send to market, can be prevented hatching by having a needle thrust through the shell at either end. You ought to explain that they are so treated to prevent a purchaser being disappointed.

APIARIAN MISMANAGEMENT (*A. A. F.*).—Your bees will not long survive stupefaction by tobacco smoke and the plunder of their stores. The best and most merciful plan will now be to kill them outright by means of brimstone, and appropriate any honey that may remain. Those combs which are of a dark brown colour have been used for rearing young bees, and their cells are empty owing to the breeding and honey-gathering season being over. Had you intended to adopt the depriving system you should have placed a small super on the hive soon after it was stocked, which might possibly have been filled by the autumn and removed without injury to the bees. On the ordinary swarming system the colony should have remained undisturbed to swarm next year, in the autumn of which you might probably have been able to have appropriated the contents of one or more hives without destroying your stock. Before again commencing bee-keeping get some cottager to teach you the rudiments of ordinary management. Buy “Bee-keeping for the Many,” which will tell you how to convert empty combs into wax, and give all the information you are likely to require. When you have in some degree mastered the subject you will yourself be able to instruct your unlettered subordinate, whose brains, as you very justly surmise, are only likely to become more added by long articles being read to him on the abstruse branches of apian science. He was, however, quite right in giving the stock a waterproof covering. Bees in ordinary straw-hives require no ventilation beyond the entrance.

GLASS OF HONEY (*N., Newark*).—Write to Messrs. Neighbour & Son, 127, High Holborn, and ask what they will give for it.

DISCOLOURED BEES (*Moorside*).—We believe the discoloured bees are simply covered with white pollen, which is no inconvenience or injury to them; but, on the contrary, a sign of the prosperity of the stock whose Lignian queen is probably “multiplying the species” with the wonderful rapidity peculiar to her race. If you still entertain the idea that the discoloration may arise from a fungoid growth, and will forward to us a few of the bees thus affected, we will endeavour to decide the point by the aid of the microscope.

GREY LINNET (*C. H.*).—Bathe the bird's eyes and feet with warm water, and give it milk and bread. It should also be kept very warm; but we fear that it is past recovery.

DOG WITH SWOLLEN EARS (*A Subscriber of Long Standing*).—Your Labrador dog has cankered ears. The following is the treatment recommended by Mr. Meyrick:—“Feed the dog on a vegetable diet only, give a dose of castor oil, and three times a-day use a lotion composed of one part goulard water and four parts water. Two persons are required to apply the lotion properly; one to hold the ear and keep the dog steady, and the other to pour in the lotion, which should be allowed to sink well into the passage of the ear. After this let a cap be placed on the dog's head, which may be made thus: Take a piece of thin calico of an oblong square shape, and large enough to cover the whole of both ears; along each of the two longest sides sew a piece of tape, having ends about 4 inches in length, with which the cap can be securely tied on below the dog's head. The object of this cap is to prevent the flapping of the ears. If made of sufficiently thin material, and if it does not press on the ears, it will not increase the inflammation, as it has been said to do. Abscesses must be lanced, and care taken that no matter is left in them. After the operation, lint soaked in the lotion may be put for a day or two in the seat of the abscess, and the ear may then be left to heal of itself.”

LONDON MARKETS.—OCTOBER 5.

POULTRY.

Trade is still lamentably bad. Little or no demand for poultry, and a large supply.

Large supply.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 58.9°, and its night temperature 41.0°. The greatest heat was 76°, on the 14th, 1845; and the lowest cold, 22°, on the 19th, 1843. The greatest fall of rain was 1.04 inch.

INSECTS AND THE ATMOSPHERE OF HOTHOUSES.

N this country, at least, all danger to property from beasts of prey has long ago ceased to exist; but it still remains a fact that the condition and industry of the human

race are seriously interfered with and injured by the deadly onslaught of insects of various kinds, with which the art and ingenuity of man have not yet

been able to cope. In some parts of the world the inroads of certain insects are regarded with terror; and the result of their collective force, with their minute and complicated machinery of destruction, baffles all the resources of man. A correspondent writing from France says that whole forests have been stripped of their green leaves—left as bare as winter by the ravages of the May bug. Humboldt tells us of a small ant which offers invincible opposition to the civilisation of certain parts of the world by devouring everything in the shape of books and parchment, so that many provinces in Spanish America cannot produce a written document a hundred years old, and the results of the genius and wisdom of the country cannot be transmitted to posterity. In other tropical countries, we are informed that a small white ant clears away whole villages as effectually as would a fire or a flood. In some parts of South Carolina the Pine trees have been destroyed to an alarming extent by the ravages of a small white bug, which at one time cleared away every tree over many thousands of acres. It is scarcely credible that the larvæ of an insect should in one season have completely destroyed many thousands of acres of trees which measured 3 feet in diameter and more than 100 feet in height. Then there is the corn weevil, which devours storehouses full of grain, by extracting the flour and leaving nothing but the husks. The ravages of the locust are too well known to need being explained, and are a wonderful example of the formidable and dreaded power of the insect race. But to come nearer home, the turnip fly and wireworm are sources of great annoyance and loss to our farmers. Our very ships are not safe from the ever-busy depredations of insects; and the embankments and docks of many parts of Europe have been threatened by the collective power of beings, the individual insignificance of which might be worthy in one sense of man's contempt.

But what, it may be asked, has all this to do with the operations which most concern the readers of this Journal? It may simply be answered that no gardener need be told how great a relation the insect tribe bears in the battle he has yearly to fight in the cultivation of many things, and more particularly in the case of those plants and fruits which have to be produced and

brought to perfection in an atmosphere artificially enclosed and heated. The little knowledge of the best modes by which insects may be impeded in their destruction of much that concerns us, and that is valuable to us on account of the labour and means which the growth necessitates, is, I think, often very forcibly brought before us, particularly in the case of the great host of amateurs which are every day stepping into the ranks of gardening. It has been remarked that the more artificial the circumstances are under which plants and fruits are cultivated, the more trouble arises from insects. While certain insects make their appearance out-doors more or less every year, and give much trouble and work much mischief, still it is in our forcing-houses that the incessant watch must be kept, and that the arm must be always prepared either for or to prevent war with some determined confederacy of insects.

The object of these notes is not so much to deal with the various compounds which are used as insect-eradicators, nor to notice their effectiveness to the end for which they have been recommended, as to call attention to a point which, it must be admitted, has not come in for that share of attention from gardeners that it deserves—namely, the application of some of the facts which Chemistry has revealed to the composition of the atmosphere of hothouses, and to ammonia as a preventive in the case of that inveterate army of redcoats named red spider, which costs us so much care and labour, and after all works so much mischief. That the temperature and moisture of the atmosphere of hothouses are matters of great importance is beyond a doubt. All gardeners who have to force flowers or fruit cannot neglect these two matters with impunity. In order to apply the two agents just named in the most exact degree Science has furnished us with instruments for our guidance. We have the thermometer to indicate the proper degree of heat, and the hygrometer to tell us to what extent the air is charged with moisture. And this is of great importance; for no matter how exactly suited to the nature and wants of a plant are the mechanical and chemical conditions of the soil in which it is planted, the heat and water with which its roots are stimulated and fed, if the heat and water of the atmosphere are either too great or too little for healthy action. So much is this a matter of importance, that were we to take the most elaborate treatise on the cultivation of any given plant or fruit, and expunge from its pages all the rules and precautions about atmospheric heat and moisture before placing it in the hands of a beginner, what a great gap would be made in the rudiments of culture! The most elaborate directions might be given on the construction of the forcing-house, and the character of the ingredients which should compose the soil in which a Peach or a Vine will grow most satisfactorily; yet without some definite rules for guidance in the matters of atmospheric heat and moisture to be maintained at the different stages of growth, the inexperienced would to a large extent be in the dark, and disaster would be sure to follow.

Ey means of cheap glass and the ever-growing compe-

tition in trade, the gardeners of this country are more than ever enabled to apply with the greatest exactness the degrees of atmospheric heat and moisture required by plants from more favoured climates than that of this country. The days of thin glass and rickety old flues are fast being numbered with the past, and more than ever are we enabled in most instances to excel the open-air productions of summer lands. It must not, however, be overlooked that the means which have been called into operation to enable us to supply with the greatest steadiness the two elements referred to, are attended with evils which require mitigation. The almost air-tight manner in which hothouses are now being constructed is productive of the deleterious influences of a close and impure atmosphere; and a pure and constantly renewed atmosphere is considered of so much importance, that means are now being put in operation by which, in the most severe weather of winter, a constant change is effected without the dangers and evils previously consequent on the admission of large volumes of frosty air for only a short period of the day. Appliances of this kind have now arrived at so advanced a condition, that it can only be by the agitation of many years and the friction of many minds that any further steps of importance can be looked for. We are apt to think so, at least, and are ready to ask, What more can be done? Can we not press into our service fresh aids to cultivation, which shall be grounded on demonstrated and self-evident principles? To what extent have we pressed into our service the knowledge which has been placed within our reach by our Liebig's and Johnstons? Or can it be said that the scientific research of such men has simply explained to us the effects produced by the toiling pains of merely practical men? Be this as it may, it is undoubtedly a fact that the practical application of the discoveries of scientific men generally proceeds with cautious steps; and we have much to thank those bold and curious spirits for, who are generally less benefited by their experiments than are the community at large. A generation produces few men like Knight and Mechi; and however such men may have benefited the art of cultivation, they are generally laughed at by no small portion of their self-satisfied compeers.

It is to be feared that gardeners are very apt to look into the researches of scientific men, and store some of the more striking facts which have been demonstrated without once attempting to reduce them to practice; and, strange to say, dabblers in matters of science are ever associated in many minds with crack-brained experimentalists, incompetency, and unsuccessful practice, just as if the possession of correct knowledge and the successful application of it were antagonistic—an idea which we fancy would be hard to prove by any species of reasoning. No one can possibly regret that the march of horticultural appliances has enabled us to free ourselves to a great extent of the labour and filth of the cumbersome dung-lining system. On the other hand, it certainly is a question whether we have not left behind us some of the redeeming points of that old and obsolete system of forcing.

Many of us well remember how vigorous and healthy many plants used to grow in M'Phail-pits heated with dung and leaves, and how many a sickly plant when placed in dung heat regained that hue of health which nothing else would impart. The almost sere and yellow leaf would become green and full of substance under the influence of the carbonic acid and ammonia evolved in the fermentation and decomposition of stable-manure, and with which no modern appliances of heat are naturally accompanied. It would be endless to refer to the many plants which thrive better, and are more free from insects under the influence of dung heat, than that supplied by either flues or pipes. Many gardeners to this day who grow Gardenias, and even one or two other stove plants which are very subject to mealy bug in the common stove, yet find that in dung heat they are comparatively free from the pest. It has even been asserted that subjecting Pines which are infested with white scale to the steam of dung-linings, will rid them of so desperate an enemy.

It is a well-demonstrated fact that carbonic acid and ammonia form the chief food of plants, and these two constituents are freely given off during the progress of the decomposition of dung-beds, and this is what accounts for the

vigorous growth and dark green appearance which dung-frames invariably impart to plants. This is the deficiency which is attached to the use of modern heating appliances; and surely it cannot be beyond the powers of the gardener's resources to charge the air in glass houses with one or both of these gases, so that the plants, largely capable as they are of imbibing nourishment from the air, can appropriate and assimilate them. Are we to conclude that an atmosphere resembling that produced by fermenting dung and leaves cannot be attained when heat is obtained from hot-water pipes? Far from answering such a question positively, it is at the same time questioned if ever such has been systematically attempted.

In potting plants we have spared no pains nor attention in feeding them through their roots with all the proper elements of nourishment. Natural circumstances are imitated to the best of our knowledge, and as far as artificial circumstances will permit. But all the while we are, it is to be feared, practically forgetting that the stems and leaves of a plant are no more in a natural condition in a very small amount of tightly-enclosed air than are the roots when cramped up into a pot. The plant is removed from the breezy air of heaven, and packed up into a glass handbox, and is too often left for long and weary hours closely shut up, to rob the air of its scanty supply of food, and to charge it with gases injurious to itself. This is something like suffocation and starvation combined, and is followed, as a consequence, by the more apparent and no less desperate evil of insects, which are rarely developed in the ammonia- and carbon-charged air of a dung-pit. Red spider and white bug revel in the one case, while in the other they are far less likely to make their appearance at all, and when they do they never become so formidable and destructive.

If these inferences be correct, it is surely time to inquire whether there are no means within our reach of producing an atmosphere in our forcing-houses more akin to that produced by fermenting dung and leaves without having recourse to the cumbersome and untidy presence of a heap of those materials. That this would be desirable in the forcing of the great majority of our plants and fruits will scarcely be questioned. There may be differences of opinion as to how best to make such applications, but their beneficial results have been of late very strongly impressed on my mind by various results. In the early part of summer it was resolved to plant a house, which had formerly been a Peach-house, with Vines. The house is a very old one, having been erected about ninety years ago, and has, consequently, many snug retreats for insects, and red spider in particular. The Vines were struck from eyes in spring, and planted-out when not more than a foot high. For a time they progressed favourably; but red spider, which has been a fearful pest out and in-doors here this year, soon attacked them, and in a very short time brought the young plants to a complete stand-still. The popular remedies were applied. The Vines were syringed, the hot-water pipes were rubbed with sulphur, and fumes raised enough to choke one, but the enemy was as active and destructive as ever. All hope of getting the Vines to the top of the house this year was given up. Their points were in some cases black and leafless from the effects of the spider and the syringe together. I then heard of an amateur who had invariably been much troubled with red spider, but who had escaped it this season, while his neighbours were being sadly annoyed with it. He attributed his success to the regular application of ammonia to the atmosphere of the vinery. I then mixed up a small potful of Peruvian guano, and applied it regularly to the pipes of the vinery, and so strongly was the air charged with ammonia from the guano that it affected the eyes on entering the house. This was regularly continued, and in less than three weeks the Vines had changed to a dark green, began to grow vigorously, and not a red spider could be found in the house. The Vines soon found their way to the top of the house, except a few which had been too severely punished by the spider ever to make free growth afterwards. The change from a pale hue to that of a dark green in the case of these Vines was next to magical.

In our Pine-pits here guano has been regularly applied to an extent sufficient to make the atmosphere smell strongly of it, and all who are in the habit of seeing our Pines are struck with their almost black appearance and their vigorous

stocky growth. These and other instances have strongly impressed on my mind the importance of imitating somewhat more the atmosphere of our old dung-pits; and seeing that the atmosphere of our glass houses is almost, if not quite, as easily influenced as the character of the soil in which plants are grown, the idea of success in the matter is far from being so utopian as many that have been broached. I believe that in the growth of some of our fine-foliaged plants—such as Begonias, Cyanophyllums, &c.—the effects of such an atmosphere would be most marked.

The intense light which is available in hothouses now as compared to former times, resulting from the use of more glass and less timber, makes it all the more probable that by increasing the amount of carbon and ammonia in the air beneficial results would follow, for the decomposition of such elements by plants is dependant on the degree of light to which they are exposed. It may be fairly allowed that it is most desirable that we should give the matter a fair trial in a systematic way. The practicals are, however, somewhat open to the charge of fixing prejudice at the garden gate like a flaming sword ready to decapitate the very shadow of any innovation which may seek to find an entrance; but it is possible to do homage to the god of science all the while; for why those continual syringings with soot water, and the preference to soft rain water to that which we draw from the bowels of the earth? Because the former is found to have a healthful influence on vegetation wherever it is applied, and the latter agrees much better with most plants than hard water from the well. Now, in both these cases science tells us that the water is largely charged with ammonia, in the one case from the soot, and in the other by the raindrops from the atmosphere in their descent from the clouds.

But the matter that I want to point to as being chiefly involved in the chemical composition of the atmosphere of hothouses is the incessant war which we find it necessary to wage against the insect tribe all the year round, and which is becoming of the greater importance from the ever-increasing amount of fruit and flowers that are cultivated under glass. There are, for instance, thrips, and bugs, and spiders, besides their numerous allies, enough at times to drive one crazy. Anything that would prevent their appearance or destroy them when they appear, would be worth something if discovered, and whoever might be the fortunate discoverer he would deserve a rich reward, and an enduring monument from all who are engaged in gardening pursuits.

Closing with the fact which I have already referred to regarding the comparative freedom from some of our most troublesome and destructive insects, when plants are grown under the influence of the gases with which fermenting manures charge the atmosphere, I would urge the trial of an imitation of such an atmosphere in the forcing-pits and houses of the present day. Whether the freedom from insects arises from such gases being unfavourable to the production of insects, or from the state of vegetation under such circumstances, matters not in a practical point of view. And while it would not be at all desirable to return to the dung-bed and lining in a general way, it is certainly worth while to try and produce the wholesome atmosphere peculiar to that old appliance by some artificial means. I have used guano in the case and manner already referred to, and, as I am warranted in thinking, with success; and it would be interesting if others would give any experience which they have had in the matter, or if they have not tried it to do so, and favour us with the results. The destruction, or still better, the prevention of red spider in our hothouses, is one of those questions which ranks of first-rate importance, and in my case I have never found the application of sulphur to the pipes effective, and the use of the syringe to such fruits as Grapes is attended with nearly as many evils as the raids of the vermin themselves.

D. THOMSON.

ROYAL ASHLEAVED KIDNEY POTATO.—We have received a few of the Ashleaved Kidney Potato from Mr. Rivers, of Sawbridgeworth, and found them when cooked a mass of flour. The flavour is excellent, and with the earliness and prolificacy which it is said to have we do not know any merit it ought to possess which it has not.

GIVE US BACK OUR FLOWER-BORDERS.

QUEEN FLORA.—“Where, gardener, are my loved plants

Which once adorned your borders and mine too?”

GARDENER.—“Your Majesty has but to look and see

Our borders rich with red Geraniums bright, and—”

FLORA (in great wrath).—“Churl! these are *bedding* plants!”

New Play.

I HAVE spoken of King Croquet as being likely to cause improvement in our small gardens. I own I am old-fashioned—some may pertly say “antediluvian” in my ideas; perhaps a residence at Hampton Court, and daily walks in its stately gardens, when an enthusiastic youth, have something to do with my gardening notions. Twenty years ago how I loved to glide along the Thames, and peer into the dear old gardens at Twickenham! How I “suspended the dashing oar” to look into the gardens of Pope’s Villa, and almost worshipped an old Cedar, somewhere, if my memory serves me, at the back of the villa!

Perhaps this early love, to say nothing of older times, when playing in petticoat trim in gardens of relations long since gone to their last home, has something to do with my love for the old-fashioned border plants, and makes me raise my voice on their behalf.

But let us look at the subject in its various bearings—let us turn it over, now this way, now that way. To begin with: there is to me a great charm in the regularity, generally to a few days, at which our old plants make their appearance—their flowering, I mean—in their old places, so that we constantly connect circumstances in our families with their blooming. Thus, not only with poor Thomas Hood do we mark an event as having happened “in the time of Roses,” but when such and such a flower was in bloom. We say, “Ah, dear! so and so was with us last year when the *Erica carnea* was in flower.” This regularity of blooming as to time did not escape the eye of Thomson, who thus sweetly sings,—

“Along these blushing borders, bright with dew,
And in yon mingled wilderness of flowers,
Fair-handed Spring unbosoms every grace,
Throws out the Snowdrop and the Crocus first;
The Daisy, Primrose, Violet darkly blue,
And Polyanthus of unnumbered dyes;
The yellow Wallflower, stained with iron brown,
And lavish Stock that scents the garden round;
From the soft wing of vernal breezes shed,
Anemones; Auriculas, enriched
With shining meal o’er all their velvet leaves;
And full Ranunculus of glowing red.
Then comes the Tulip race, where Beauty plays
Her idle freaks; from family diffused
To family, as flies the father-dust,
The varied colours run; and, while they break
On the charmed eye, th’ exulting florist marks,
With secret pride, the wonders of his hand.
No gradual bloom is wanting; from the bud,
First-born of Spring, to Summer’s musky tribes;
Nor Hyacinthus, of purest virgin white,
Low bent, and blushing inward; nor Jonquills,
Of potent fragrance; nor Narcissus fair,
Nor broad Carnations, nor gay-spotted Pinks;
Nor, showered from every bush, the Damask Rose.
Infinite numbers, delicacies, smells,
With hues on hues expression cannot paint,
The breath of Nature, and her *endless* bloom.”

This is indeed a delicious flower-picture. We see—we almost smell—the glorious flowers. In fact a well-kept border, in addition to its other excellencies, is a floral almanac.

Then, too, it pleases my mind to think and wonder how long it took our forefathers to collect and arrange their flowers, culled some from wood, some from water’s brim; then how gradually they learned from experience that such a flower would bloom in February, such another in March, and so on; and how they must have watched to see if these rules held good year by year.

We force our flowers. Well, be it so. A flower in one sense can never be out of season; but still Nature reigns supreme, for no forced flower is equal to one of the same kind coming “in its due season.”

But, again, who that loves a garden does not love a flower (I mean an individual plant), almost like a living personal friend? On revisiting the home of my boyhood in the flat fens of Cambridgeshire I rushed to see if my old Mezerion tree was yet living. It was gone; but I did find some of my old Rose bushes, Moss, Cabbage, and Maiden’s Blush. Nothing like Roses on their own roots: ye votaries of the budding-knife, hear and heed!

I repeat, we dearly love our old flower plants, but bedding plants live as a rule—at least we keep them, but one year, then the cutting takes the place of the old plant, and other cuttings succeed in other years. Now, my good friend whose garden border I feebly described in "King Croquet," often points to flowering plants with such remarks as these, "That was given me by a poor fellow now in Australia; that by a lad I nursed in a long illness."

Many of your readers doubtless live in parts of England destitute, like this fen country, of great natural beauties, but

"Need no show of mountain hoary,
Winding shore or deepening glen,
Where the landscape in its glory
Teaches truth to wandering men.
Give live hearts but earth and sky,
And some flowers to bloom and die."

(All the better if they do not die for many years.)

"Homely scenes and simple views
Lowly thoughts may best infuse."

I remember a dear old lady in Scotland, far on towards eighty years of age, who—God in mercy having spared her eyesight—used to sit and work at a little table, which always had upon it pots containing common, I mean by that not rare, flowers. Upon my noticing this circumstance to her she said, "Ah! everything has changed since I was a girl, except my flowers; that is why I have them so near me, for they are my oldest friends, so I give them the place of honour."

Supposing this Geranium fever lasts for many more years, our old border plants will become as rare with us as small birds are in France. Something like it has already begun, for I have been served in this way: "Can you tell me the name of this plant?" said I to a young and well-educated gardener. I received for answer, "Really, sir, I do not know. We gardeners have, as you know, done away with border plants, and do not cultivate them anywhere. An old woman in a cottage can best tell you the name."

This, to say the least, is unfortunate, for Flora ought not to lose one gem from her glorious crown. God has given us leaf and flower, various forms of leaf and shades of flower—as much of beauty in the one as the other. What a pleasure there is in raising with hand or outstretched walking-stick some little lovely border flower nestling in its leafy bed, and turning its bright head upwards to be admired! We must not think that *all* floral beauty, though indeed there is much, resides in glowing masses of rich hues, which we have to perfection in beds; and I think we should not allow our borders to be given to the same tribe. But, unfortunately, of late years the gay crew have in too many gardens dismissed with drooping heads, but never with ignominy—that would be impossible—the charming old border plants.—WILTSHIRE RECTOR.

GLADIOLUS FAILURES.

I RESIDE within a short distance of three nurseries, all of which grow large quantities of Gladiolus, that the public may see them in bloom and make their own selections in purchasing, their's being newly imported or well-ripened bulbs. The flowers are splendid, and cannot fail to enamour all who admire beautiful flowers: consequently bulbs are ordered to be delivered when at rest. I received a visit from one of the above nurserymen on the 20th of September just past, and was invited to see his beautiful display of Gladiolus. Accordingly I went over and took my better half to enjoy the pleasing sight; and, on arrival at the place, seeing no one present to show us the sight, we strolled on until we came to a large patch of Gladiolus, but which were evidently not intended to have been seen by us, for, while we were commenting on them, the proprietor arrived to escort us elsewhere. In answer to my question why all those Gladiolus were so late (as evidently not one could flower this season, the spikes being not half developed), he replied these were bulbs left unsold, and only planted at the end of June or early in July. I, therefore, beg to ask you and other growers through your Journal, if these bulbs can be ripened and matured sufficiently to bloom satisfactorily in 1864 by any ordinary grower? My experience leads me to say No, and I am convinced I have failed to bloom four

dozen of last spring's-purchased bulbs of Gladiolus chiefly through this cause alone. If nurserymen are determined to have the first blooms after importing the bulbs, and sell these mixed with all their half-ripened ones, need there be any wonder at the disappointment and complaint you so frequently hear of and publish?—T.

SPRING GARDENING.

AMONGST the most ordinary objections made to the present fashionable system of bedding-out, there is not one more frequently brought forward than that it leaves the gardens bare for a large portion of the year, and that persons sacrifice the appearance for nine months in the year for the brilliant display of barely three; and many persons, it is to be lamented, seem to resign themselves to this condition as if it were hopeless to attempt a remedy. Assuredly such a state of things need not be the case, and this conviction arises both from personal experience and from observation of the manner in which the difficulty is met on the continent—for "they manage these things better in France." A few hints as to the best method of meeting the difficulty may not be unacceptable.

There are two classes of plants by which this object can be effected—bulbs and annuals, the main dependance being placed on the former; and considering the extensive area over which, owing to modern horticulture and skill, we are enabled to travel, there is really no difficulty in having one's garden gay from the earliest spring months, at a comparatively trifling expense. We do not, of course, mean that the garden will present at any one time such a blaze as when Verbenas, Geraniums, &c., are all in full force together; but a very nice display may be made by having a succession in which the various species of bulbs will play an important part. There is, it is to be remembered, one great advantage in this tribe of plants—that their bloom is almost certain. The Tulip, Crocus, Hyacinth, &c., have their flowers already formed in the bulb, and it will only require the most ordinary care to develop them in full perfection; whilst in other things the seed has to be sown, or the cuttings made, and "many a slip between the cup and the lip" may take place before the bed is thoroughly in bloom. And, again, they have the advantage that as soon as the bloom is over they may be taken up, removed to a spare place in the kitchen garden, and there allowed to mature themselves, and be ready for the following spring, while the vacant spaces may be immediately filled in with the bedding plants.

So much has been said on the subject of pot-culture and window-gardening, and such copious directions are given with the various articles in the catalogues published by the leading firms, that I shall confine myself to the flower garden, and endeavour to show how the space occupied by bedding plants in summer may be managed in spring. I would, then, advise that where beds are bordered with either the white Alyssum or Cerastium that this be done in the autumn, the plants be taken up, divided, and replanted. By this means a neat border will be given to the beds; for as these plants are perfectly hardy they will not suffer from the severity of the winter.

In some of the beds the Crocus may be used for the earliest bloom, a good broad border of it being, I think, the most effective way in which it can be employed; for if the bed is made to depend upon Crocuses entirely, their long foliage, when they have done blooming, is apt to make it look untidy. Many fine varieties of Crocus may be had for this purpose, while brilliant yellow, blue, and white will really be the most desirable for contrast. No one could think of dispensing with the little Snowdrop; and when to these we add the beautiful brilliant blue Scilla sibirica, we have named the most beautiful and useful of the early-flowering spring bulbs. To these succeed the Hyacinth, Tulip, Ranunculus, Anemone, Narcissus, &c. The Hyacinth, it will be remembered, as well as the Ranunculus and Anemone, are dwarf, and should occupy places corresponding. No one need be told of the great beauty and fragrance of this lovely spring flower, and I would, therefore, advise that it be extensively used. Here named selections would be out of place; excellent bulbs in distinct colours can be procured of all the seedsmen, and they can be used according to taste. But

the bulb in which most reliance may be placed is the early Tulip, and we greatly wonder that it has not received more attention. The beautiful dwarf Van Thols, the gorgeous Duchesse de Parma, Vermilion Brilliant, Garibaldi, &c., make an appearance which when once seen will be ever afterwards appreciated. And let it not be thought that this involves a vast expenditure; an assortment of both expensive and cheap varieties is always to be found, so that according to the wishes of the amateurs they can be supplied.

The centre of the parterre should be devoted to the taller-growing varieties of Tulips, shaded-off according to their colour, and arranged as to their height, the Van Thols being the lowest-growing. The arrangement must so much depend on the form of the beds, the extent of the ground, and the taste of the owner, that no detailed directions can well be given. Where there is a shrubbery in the background I would suggest a row of *Dielytra spectabilis* as forming a most beautiful finish; while, in order to give a more lengthened period of bloom to the beds, plants of the common Forget-me-not and *Silene* may be planted in them; and when the bulb-bloom is over, as of Hyacinths and Van Thol Tulips, the stems may be cut down nearly to the ground, and all may be cleared away together in the middle of June. In fact, the combinations are endless, and the hints that I have thrown out will, I hope, be sufficient to induce amateurs to be no longer contented with empty beds in spring. In the gardens of the Champs Elysées and Parc de Monceaux, where, let it be remembered, the winters are as cold as ours, if not colder, I saw in May many beds of annuals in full bloom. The attempt at the same effect in the Royal Horticultural Society's Gardens was not a very happy one; but when once put into the right track I have no doubt that the good taste and zeal of our great army of amateur horticulturists will make the spring garden as much a point of interest as the summer one.—D., Deal.

"WHAT CONSTITUTES HIGH CULTURE IN EPIPHYTAL ORCHIDS?"

[To the above somewhat vague query sent by a correspondent signing his letter "ORCHIDOPHILUS," Mr. Appleby has sent us the following reply.]

To describe the dimensions of any plant or tree so as to give the reader a correct idea of its size, is not an easy task without drawings. An instance occurs to my mind: We are told that the *Wellingtonia gigantea*, a tree found in California, grows to the enormous height of 300 feet, and is 27 feet in diameter. Now, to any one unaccustomed to measuring timber, such numbers give no definite idea of the immense magnitude of such a truly magnificent tree; but by comparison or some other mode we can give to the most ignorant person a tolerable idea of its great size. I will try one way of doing this. The diameter is 27 feet.—Now, suppose there are four men 6 feet high each; place one on the ground and another on the top of the first, a third on the second, and a fourth on the third, the four will then reach to an altitude of 24 feet. Then place a boy 3 feet high on the head of the last, and then the diameter of the tree would be equalled. Next measure a hundred yards in a straight line, and set up a stake at each end—that would show the length the tree would reach if it were felled. Further: Supposing it were necessary to cover such a felled tree, it would require a building 100 yards in length and 9 yards in height to contain it.

"ORCHIDOPHILUS" desires to know the dimensions of the largest pseudo-bulbs of *Calanthe vestita* grown by my friend Mr. A. North, at the Lodge, Ashton-upon-Mersey. In order to be able to give the correct size, I was at the pains to go there to measure them. It happened to be at the time when they were at rest, consequently they could be more easily measured. I took a piece of tape and passed it round one of the bulbs. It measured exactly 14 inches. That was lengthwise. I then put the tape around the bulb in the thickest part, and found that to be 9 inches. Now, let "ORCHIDOPHILUS" or any other grower take one of their pseudo-bulbs of this fine Orchid, and compare by measurement the size of that bulb and note the difference. They were at least one-third larger than those "ORCHIDOPHILUS" alludes to which I mentioned in my "Manual of Orchid Culture," a

book which I am glad that he has found useful, and I trust he will eventually succeed in obtaining pseudo-bulbs quite as large as described above.

His next inquiry is, "What constitutes high culture in epiphytall Orchideæ?"

As example is better than precept, I would advise him and other young growers of these singular and most interesting plants, to visit the most celebrated collections at several seasons of the year, and observe the state and perfection to which, by high culture they have been brought. I would particularly recommend an inspection and study in a cultural point of view of the large collection at Messrs. Veitch's Royal Exotic Nursery, at Chelsea. There may be seen plants of Orchids grown as they should be, and in such numbers of even the rarest species as would astonish a small grower, though at such places it is hardly fair to expect to see the finest specimens or examples, because Messrs. Veitch and other nurserymen grow their plants for sale, and whoever will give the price for the finest specimens can have them; but one thing is certain, that every grower for sale exerts his utmost skill to bring them to the highest state of cultural perfection. Useful lessons in culture may be obtained at other nurseries, such, for instance, as Mr. Williams's, at Holloway; Messrs. Rolisson's, at Tooting; Mr. Maule's, at Bristol; Mr. Woolley's, at Cheshunt; and others.

It is, however, in private collections that examples of what constitutes high culture may be best observed. I am glad to notice that these examples are increasing, and I hope "ORCHIDOPHILUS" himself will be one of the number. I will mention only the following—namely, Mr. Rucker, at Wandsworth; the Bishop of Winchester, at Farnham; Mr. Aspinwall Turner, near Manchester; the Duke of Devonshire, at Chatsworth; Mr. Horatio Nicholls, near Bowden, Cheshire; and Mr. Reed, near Bridgwater. At these and, no doubt, many other places, fine examples of the high culture of Orchideæ may be studied with great advantage by new beginners of Orchid-growing. I may, however, mention, that well-grown plants of this tribe should be perfectly healthy, and every succeeding pseudo-bulb should be annually larger, with leaves of increased size, till the maximum is reached. The Indian species, such as *Erices*, *Saccolabium*, and *Vandas*, should be strong and robust in health, with leaves of a full green colour without spot or blemish; and each plant, where it is the habit to be so, should have many shoots all equally strong and healthy. Plants so grown would be in a state of high culture.

Our correspondent next states that he has seen a collection of Orchids that had been neglected, showing a regular degeneration, and he wishes to know the cause and the remedy. As to the cause, it must necessarily be in a great measure guess work.

Plants in such a state as he describes must either have been grossly neglected or managed by a person almost totally unacquainted with their culture, or, perhaps, possessing inadequate means to grow them—with such, for instance, as insufficient heat and moisture in the air, improper soils, or an indifferent house to grow them in; or, lastly, his time may have been taken up with other departments of gardening, so that he could not devote sufficient attention to this class of plants.

To bring such plants back to a state of normal luxuriance would require the reverse of the treatment they have been subjected to. The first point to attend to would be to improve or rebuild the house or houses they are to grow in. See that there are plenty of pipes to heat the atmosphere, and means devised to give out moisture during the growing season. Air must be given when needed, and that air should pass over the pipes, so as to be heated before it reaches the plants. Then procure the necessary requisites of fibry peat, sphagnum moss, charcoal, cocoa-nut fibre, fibry loam, leaf mould, and caky dung. All these are necessary where a tolerable collection is to be grown or brought into renewed health. Also have clean pots, good sound logs and baskets, and plenty of broken pots of at least three sizes. All these being obtained, take the deteriorated plants, shake them out of the old soil, wash them thoroughly in tepid water so as not to leave one insect, and then cut away all dead or decayed roots and dead pseudo-bulbs. Do this at a time when the plants are not growing. Then repot, rebasket,

and relog the whole, and place them in the sweet clean house, giving no water till shoots and roots appear; only give moisture in the air pretty freely, to keep them plump, and encourage them to grow both at the top and the roots. The cultivator must not expect such a neglected collection to improve even with the highest culture in a short time—it will take three or four years to bring them into normal luxuriance. If he has not had much experience, let me advise him to procure some work on their culture; even the humble one our correspondent alludes to will be useful.—T. APPLEBY.

CENTAUREA CANDIDISSIMA AS A BEDDER.

As there seems to be some difference of opinion about the merits of this plant for bedding purposes, it would be of great service to the gardening world if those who have had much experience of it would report upon the subject. My own has not been sufficiently extensive to enable me to give an opinion without some reservation; but others, perhaps, can write more decidedly. What little experience I have had is greatly in its favour, and the condition of my plants during the greater part of the summer left nothing to wish for. Some growers, however, say that it becomes too rank, and when so its foliage assumes a dirty grey instead of the beautiful white which it in general presents. Are its detractors right or not? I fancy myself that the majority of those who grow it will affirm the contrary, but if otherwise let them by all means be heard.—H. T. V.

[We shall be obliged by reports on this subject, whether success or non-success attended the attempt to bed this plant, with details of the culture adopted, and the nature of the soil.]

HERBACEOUS CALCEOLARIAS.

"AN ADMIRER OF CALCEOLARIAS" wishing for hints on their cultivation, will, it is to be hoped, find something in the following suitable to his case. These charming plants are natives of the mountain ranges of Chili and adjacent countries, and delight in the rich vegetable mould found on the margin of forests, the same as the Foxglove, to which they are closely allied, does in our own country.

Calceolarias may be had in bloom at different periods by periodical sowings of the seed, but three sowings will be ample for most places. For a spring display, the seed is sown in the middle of July; for summer flowering, in the last week in August; and a sowing in spring gives fine autumn-flowering plants. The two first sowings require no artificial heat, but the last is placed in heat.

Seed of first-class excellence should be procured, avoid low-priced seed, and by all means let it be new. The starting into flower prematurely is greatly to be attributed to old seed, whilst vigorous growth is promoted by sowing new. The soil for the sowing should consist of turfy loam and leaf mould in equal parts, with an admixture of one-sixth silver sand. The seed-pan or pot should be half filled with drainage, and on this place the riddings of the compost, for it should pass through a half-inch riddle. Providing the drainage and riddings occupy three parts of the depth of the pot, fill with the compost, and level the surface. Water, so as to thoroughly moisten the soil, through a fine-rosed watering-pot; sow the seed thinly upon the surface, and scatter a little silver sand over it so as to make the surface of the soil white all over. Place the pot in a shady place out-doors, and cover with a hand or bell-glass, or a close cold frame will answer as well. Guard against exposing the pot to sun and currents of air, and keep the soil just moist, but not very wet. Look out every now and then for snails, for these pests will clear a pot of seedlings in a single night and leave nothing behind them but their slime and the roots beneath the surface. A little soot sprinkled round the pot will make all safe in that respect, and may save the raiser the trouble of complaining about the badness of the seed. All watering should be made through a fine rose, and shade must be given if the place is exposed.

When the plants are fairly up admit a little air, but avoid draughts. Gently bedewing the plants in the morning will keep them cool and moist during the day. When the

plants have a pair of rough leaves the size of the thumb-nail, pot them singly into 60-sized pots in the same compost as before, and place in a close cold frame in a shady spot. Keep close and shaded for a few days until growth commences; then admit a little fresh air, and give enough water to keep them growing freely. When the plants become established admit air freely by taking the lights off at night, and in cloudy weather, and thus give them the full benefit of dews, gentle rains, and a damp but not stagnant atmosphere. Dryness is the greatest bane to contend against in Calceolaria-culture, for if the plants are kept dry green fly is difficult to keep down, and they flower prematurely. For that reason the lights had better be kept over the plants during the day and the frame tilted or stood on bricks placed flat-wise at each corner, so as to prevent stagnant air lodging, or the frame becoming hot inside. A gentle sprinkling of water overhead morning and evening in droughty weather will much invigorate the plants; but they should be shielded from heavy rains by putting on the lights, and shaded from bright sun.

The plants must be potted immediately on the pots becoming filled with roots, for cramping them in small pots tends to cause flowering before the plants are half formed. Shift them into 48-sized pots, using the same compost as before, placing in the frame, &c., as at the first potting. When the roots reach the sides of the pots, pot into 32's, using a compost of loam from rotted turves one year old and leaf mould in equal parts, with half the bulk of cow-dung two years old, and add about quarter of the whole of pieces of charcoal the size of a hazel nut, and silver sand. Water freely in addition to lightly syringing morning and evening, admit abundance of air, and give all the light practicable without bright sun.

In October (I am dealing with the seeds sown in July for blooming in May) the plants will need shifting into 24-pots; but as there will be some very strong whilst others lag behind, discriminate between a strong plant and a weak, potting the first, but merely examining the last to see that the drainage is all right; then place in a cold frame with a southern aspect, for we now want light and warmth.

Any plants that are very sickly ought to be shaken out of the pots, removing all the earth without injuring the roots, and potted in the compost recommended for seedlings in a size very little larger than just sufficient to hold the roots without cramping them. If the cultivator's stock be large he may discard the sickly plants; but it is only right to caution the uninitiated against throwing away that which may prove superior in colour, spotting and blotching, form and substance, to any in the patch. I have known the sickly-looking considered so; but really weak growers afford the most novelty, and the finest-formed and coloured flowers in patches of seedlings. These weak growers, whether weak by nature or accident, will form capital succession plants, and first-class specimens of small size for filling up gaps on front stages in the conservatory. When the nights are becoming frosty in October or November remove the plants to a pit, placing them near the glass, and as far from the heating apparatus and currents of dry air as possible without subjecting them to frost or allowing stagnant air to lodge near them. The plants cannot have too much light and air; but care should be taken that the air does not become dry, nor that they flag from want of water at the roots or a deficiency of moisture in the atmosphere. Damp or stagnant air should be studiously avoided, and drip prevented falling on the leaves, or moisture of any kind lodging between the leaves or on them for any length of time. The shelves of a greenhouse are a good place for wintering Calceolarias, but not equal to a pit, though I have had them in 12-inch pots with a head of bloom between 2 and 3 feet in diameter with over a thousand flowers upon them at one time. The main points to attend to during winter are to keep the plants gently growing without giving warmth to make them grow quickly, and, if dark and close, to become drawn and tissue-like in the leaf. Any shoots that grow straggling should be stopped; but it is a bad practice to stop one shoot and not another on the same plant, for it tends to promote a succession of flowers; whereas the beauty of the plant consists in all the blooming-stems appearing simultaneously.

If all go on well the plants will have leaves the size of a lady's hand by Christmas, when they may be potted into

18-sized pots and gently bedewed with tepid water in the morning, care being taken to have the leaves dry before the sun goes down, for water left standing on the foliage is apt to cause that part of the leaf where it rests to damp or decay. Water must be given more liberally as the days lengthen, but it is well to let the plants need it before affording a supply. A little now and then does no good, but an occasional thorough application, enough to run through the pot and so wet the soil quite through, is worth all the surface-waterings put together. No watering is necessary before the soil becomes dry, but not so much so as to make the leaves flag. Water should be given before that takes place.

By the latter part of February or beginning of March the pots will be full of roots, when the plants must be shifted into pots a size larger or into 12's, using the soil a little rougher, chopping instead of sifting it. The plants will now require syringing morning and evening; in about three weeks from this time the pots will be again full of roots, when the cultivator should consider whether he would like the plants to bloom in the pots they are already in, or if he would like them a little larger and finer. The strongest will be chosen and potted into 6-sized pots, giving extra drainage, and using the soil rough. The pots will soon be full of roots, and when these begin matting round the sides of the pot the flower-stems appear. At this stage keep a good circulation of air and the atmosphere of the house moderately cool, without shading, and so induce the flower-stems to rise strong and dwarf, and if so, no sticks will be needed to support the massive heads. I never attend an exhibition without being puzzled to know whether it is the number of sticks and ties that win their owner the prize, or the distorted blooms on their lanky stems. The plants are to be lightly syringed morning and evening until the flowers burst the calyx, when moisture must be given by sprinkling the paths and shelves occasionally.

When the blooms have attained half their full size, they should be shaded from very bright sun, and when fully developed, their beauty is much prolonged by being shaded from ten to four o'clock. It is not necessary to repot so often, to give more than one shift in the spring, nor to attend to one-half the minutiae here laid down, but I have given the essential particulars of their cultivation, the nearer to which the grower adheres the more likely is success to attend his efforts. The drainage in all cases of repotting should be perfect, and this is secured by placing a large crock on the hole in the pot, an inch of rough crocks, half an inch of finer, and a layer of live sphagnum, or cocoa-nut fibre half an inch thick upon that. It is not a bad practice to pot rather low, especially if few shifts are given, for then the pots can be top-dressed, for the *Calceolaria* emits roots from the stem, and these are preserved and extended by the top-dressing, which promotes healthfulness and vigour. Plants that are not shifted repeatedly until the flower-stems appear, will be much benefited by the application of weak liquid manure twice a-week.

Plants done blooming are to be plunged in coal ashes in a shady place, but exposed to the air. All the flower-stems having been removed, fill in the openings between the plants with leaf mould, putting it close to the stems. Into this the young shoots will root, and when they are sufficiently advanced slip them off the parent, and insert them in 48-sized pots in the compost recommended for seedlings. Place in a cold frame, and keep shaded until well rooted, when they may be treated as seedlings of the same season, or like July seedlings. The established or old plants are to be potted in the last week in August in pots sufficiently large to contain them, without cramping them, after the removal of all the old soil that comes freely away without injuring the roots; then place in a cold frame that they may recover the disrooting, when they require the same shifting and treatment as seedling plants.

The seedlings sown in the autumn must be potted when large enough, and they may be wintered in 48-sized pots on shelves near the glass in the greenhouse. They will require potting in March, and shifting into their blooming-pots in the end of April or beginning of May.

Spring-sown plants are raised in heat, care being taken to keep the atmosphere moist and healthy, yet free from draughts. When of sufficient size they are potted-off, and

gradually hardened-off, as with half-hardy annuals, by the middle of May. The seed, to do this, should be sown in the first week in March: the plants are then placed in a cool frame, and shaded from scorching sun, which is apt to cause the flower-stems to come whilst the plants are small. Shade and moisture, with repotting as often as the pots become filled with roots, will keep the plants growing vigorously until the last week in July, when they must be potted into their blooming-pots, giving them the full benefit of the sun's rays, and sprinkling them lightly morning and evening with water until the flowers appear, when they may be removed to a drier atmosphere to bloom. Such plants, however, are seldom half so fine as those kept over the winter; but if not allowed to produce many flowers in autumn, and kept over the winter, and frequently repotted, they make very fine early-flowering plants, and afford in the April and May following a display which no occupant of the greenhouse, not excepting the *Azalea* and *Cineraria*, can rival.

Green fly is very troublesome in attacking the *Calceolaria*, and is mostly brought on by keeping the plants in a close confined atmosphere, and by imperfect drainage. A sour soil also induces the attacks of this pest and of mildew; whilst a too dry atmosphere is instrumental in bringing on thrips. The plants should be smoked with tobacco on the first appearance of green fly and thrips, but the leaves should be dry; and it is better to smoke slightly two nights consecutively than give a strong dose on one night that not only kills these pests but injures the leaves as well. Mildew may be removed by dusting the infested parts with flowers of sulphur, and damp may be prevented by removing the causes—stagnant atmospheric moisture, and water lodging on the stems and leaves.

Shrubby *Calceolarias* must form the subject of another communication.—GEORGE ABET.

BILLBERGIAS AND THEIR CULTIVATION— ECHMEAS.

It but too often happens that this valuable genus, though represented in almost every stove we visit, receives but secondary consideration and treatment. This is undeserved considering its known merits, its singular foliage, and the brightness and uses of its flowers. Such treatment may often arise from the simple supposition that the plants grow and seem to flourish well under the roughest system of treatment. That these ideas are wrong I scarcely need state, or that such treatment does very poor justice to this or, indeed, any other class of plants, for by cultivation they may be induced to form much finer foliage and to flower much more freely than they usually do.

The general system of treatment I would follow would be to pot them each year, in May, in a compost of peat, sand, and charcoal, adding a few well-broken potsherds; to afford them but a slight shift each time, taking care to pot them firmly; and to give them up to September a general stove temperature and treatment. It is also necessary to bear in mind that where good drainage is afforded they are fond of an abundant supply of water during their growing season. At the first opportunity after September they should be placed in a higher temperature and receive the general treatment of a Pine plant when the object is to induce it to fruit. I have omitted to state that all growths remaining upon the plants which may have previously flowered, or may be older than those of the last year, should be carefully removed with a keen-edged knife, for by permitting these to remain upon the plants they appropriate to themselves a part of the sap, all of which should go towards the perfecting of a large strong growth, with a view to efficient flowering. In some of the varieties the flower-spikes push out rather too far to sustain their weight, and in such case they may be properly secured by being tied. Others which are not so long and are stronger in the stem will require no support.

The sorts generally known are *Billbergia Leopoldi*, *anæna*, *fasciata*, and *Duc de Croy*. I have known some very lively-flowered sorts under the names of *Morelliana* and *Liboniana*, though, in consequence of greater notice not having been taken of them, the collection is not so complete in some popular catalogues as it might otherwise be.

Echmea is another very pleasing genus, and very closely

allied to the preceding in its form, habits, and mode of flowering. The remarks given above will serve generally for the successful cultivation of these also, though perhaps our favourite, *Echnea fulgens*, will by a distinct treatment submit to our wishes more readily than any of the others. The way this is now generally treated is the following:—Take off with a sharp knife any young shoots about three parts grown, place them upon the tan in a Pine-pit, or on the soil in a Cucumber-house, or in any other place where a high moist temperature is kept up, where they will eventually root. When rooted the cuttings should be carefully potted into 48-pots in a composition similar to that detailed for *Billbergias*, but with rather more sand, potsherds, and drainage. Continue to keep them in a warm moist atmosphere until you suppose they are well established or are showing for flower. They come quickly into flower when permitted to remain in heat; yet when we wish to retard their period of flowering, it does not injure them to remove them into a lower temperature for a time.

Besides this, other modes of obtaining a succession of flowering plants might be practised, such as taking off the cuttings at twice, the strongest first, or by removing half or so from the higher temperature when the young plants have become established, and when they show any signs of flowering to return them into heat as required. Grown thus they are exceedingly useful for drawing-room or other decorations, lasting a long period in flower. They are very effective when tastefully arranged in a stand with some of our more graceful Ferns.

Of the kinds I like *fulgens* best, though the beautiful and evenly balanced markings upon *discolor* constitute it a very pleasing object. Besides these there are *Milnioni*, *spectabilis*, and *miniata*. They should have all the sun and light possible.—WILLIAM EARLEY.

THE ARRANGEMENT OF COLOURS IN THE FLOWER GARDENS AT APLEY TOWERS, RYDE.

WHERE flower-gardening is carried on to any extent and carried on with spirit I think it adds very greatly to the general effect, and gives a varied charm and interest to the whole when the system of arranging the colours is varied as much as possible in the different gardens or divisions into which the pleasure grounds and flower gardens may be divided. By way of illustrating more plainly what I mean, I will as briefly as possible give a short outline how I have had them arranged here this season.

I think it gives additional interest to the pleasure grounds to have the flower borders and beds altered in their arrangements each succeeding season as much as can be done, so that the family and visitors may not have the same arrangement often repeated in the same place, however pleasing and attractive it may be in the general effect.

The mansion here stands upon the top of a piece of ground gently rising from the west, north, and north-east, and these three sides are open—that is, free from trees, while the rest is pretty well closed in with large trees and shrubs. On the east, north, and west are the flower gardens, and nearly all are seen from the windows. On the three sides of the mansion, as stated above, grass extends for several yards; then comes the terrace walk, and beyond it there is grass to the top of the terrace bank, which gently slopes for 9 feet. On the east side, and level with the terrace walk, is a flower garden in grass having the beds all of one colour, excepting a small edging of a different colour to contrast with the bed as much as the means at command will allow. Forming part of this garden is a set of smaller beds, all filled with *Verbenas* of one colour, and each bed differing from the one adjoining to it. This composes the flower garden on the east side of the house.

The flower garden on the north side lies beyond the slope of the terrace bank—it is a polychrome garden having a walk running round it, and joining the terrace walk by a flight of steps. Here each bed has been confined to two colours—that is, the bed is filled with one colour, excepting an edging of another contrasting colour. This garden is flanked on three sides with vases filled with gay flowering plants.

The first garden on the west front is on the same level below the terrace as the one just described as being on the north side. It forms half a circle, having its base towards the house and terrace bank. It is likewise a polychrome, but quite different in design and execution; its principal feature being a centre of grass, on which is a pedestal surmounted with the figures of two boys contending for some fruit, and from this centre radiate the principal walks. This garden like the north one is surrounded with a walk, and the base is connected with the terrace walk by a flight of steps. On the top of the balustrades are two boys in bronze, apparently requiring all their strength to hold and restrain a struggling fish.

The bottom of the balustrades is ornamented with vases full of *Geraniums*, and the sides of the flight of steps to the north flower garden are also ornamented with vases filled in a similar manner.

The colours in the beds in this, the west, polychrome garden are more in the ribbon style—that is, there are three colours, the centre being a good contrasting colour, each side of another colour, and the margin of a different hue. These beds fall from the centre east and west. They are flanked with four small round beds, each of one colour, two on each side. Each pair of these round beds is divided by a longer irregular bed filled with one colour, the same as the corresponding bed on the opposite side.

Beyond this flower garden the ground falls again. Another flight of steps, right opposite to and in a line with the flight of steps which connects this garden with the terrace walk, descends to this portion of the grounds, which is by far the largest.

As stated already, the west side of the garden just described forms half a circle, this flight of steps being in its centre. At the bottom of the wall, which is completely covered and hid with *Laurustinus* and *Fuchsia Riccartoni*, which flowers more or less all the summer and autumn, is a flower-border about 12 feet wide and 300 long. This border is planted in the panel style, every 11-feet long forming a square, differing in colour from the one adjoining it; and running along the entire length at the back is a row of the blue *Ageratum*, and next is a row of yellow *Calceolaria*. Each square is divided by three rows of *Calceolarias*, the centre one being *Rugosa*, the two others *Prince of Orange*. Next the grass is a row of *Alyssum variegatum*, next to this is a scarlet *Verbena*, and then *Rugosa Calceolaria*; so that each square has three rows between it and the grass, three rows between each other, and two rows at the back. In the centre of each square stands a plant of *Humea elegans*. This border forms the fourth style of arranging the colours.

Running at nearly right angles from the north end of this border, and passing under large Oak trees, is a serpentine border 76 yards long. It is not everything that will answer well under the shade of trees. This border is well seen from the corner of the terrace walk: hence it is desirable to have it look gay and as trim as possible under the circumstances. It is backed with low shrubs, and we have this season a ribbon of four colours in it. The back row is the blue *Ageratum* staked up; then *Calceolaria latifolia* likewise tied up; next, French Marigold with their varied colours, and the row next the grass is the white variegated *Balm*.

Fifth arrangement. At about 12 yards in front of this border, but not quite parallel to it, is our principal ribbon-border. This has a gentle curve, backed with shrubs, and is well seen from the terrace walk, which may be from 12 to 16 feet higher. It is 12 feet wide, and is composed of nine colours, the back row being Sweet Peas neatly staked up, then follow the blue *Ageratum*, *Perilla nankinensis*, *Calceolaria rugosa*, *Geraniums* Flower of the Day and Tom Thumb, Purple King *Verbena*, *Cerastium tomentosum*, and next to the grass is the bright low-growing *Verbena Array*. The outside of this curved ribbon-border being seen by the promenaders on the terrace walk, the effect is better than were it straight, having one end to the terrace.

Sixth arrangement. A little to the south of this border are a number of large beds filled in their middle with *Rhododendrons*, &c., which, of course, flower early in the season. Each of these beds has amongst the *Rhododendrons* a few *Hollyhocks* and some *Dahlias*, *Lilies* and *Tritoma nvaria* giving variety and extending the season of bloom as long as can well be done; all round each of these beds are two and

in some instances three rows of flower-garden plants. Some have the back row yellow *Calceolaria*, with Scarlet Geraniums in front; others have the back row Petunias; as they grow they are held back against the Rhododendrons by small stakes, so that by August the plants are growing away amongst and upon the Rhododendrons, and present at a little distance slightly the appearance of a bank of flowers, backed up with Dahlias, &c. This forms the last style here of arranging the plants and colours in the flower gardens, besides mixed borders, which to some minds are a great and a pleasing relief from the more formal styles.—GEORGE DAWSON.

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.—OCT. 6, 1863.

FLOEAL COMMITTEE.—A meeting of the above Committee was held this day. A very few entries were made either of plants or flowers, and nothing of any great interest was exhibited.

Messrs. Low sent some new Orchids—*Cattleya irrorata* elegans; *Sophranitis grandiflora*, a fine variety of this species; and *Dendrobium eburneum*, a promising flower, but not in condition, although sufficiently developed to show its qualities. This, being a new variety, was awarded a first-class certificate, and when seen again will doubtless realise all that is expected of it.

Mr. Bull sent four small plants of varieties of scarlet Pelargoniums, the plants were merely cuttings, Novelty, a bright cerise well-formed flower being the best; *Petunia Edith*, no improvement on better kinds; and *Pandanus candelabrum*.

Messrs. Smith, Dulwich, sent again four specimens of their hardy herbaceous *Anemone Honorine Jobert*, a very good and useful autumn plant, producing an abundance of white flowers. This plant was commended at a previous meeting, and now received a second-class certificate.

A few seedling Dahlias were sent by Messrs. Bragg, Slough, and Mr. Burgess, but out of condition. A few Pansies were also sent: these were out of season and very imperfect.

FRUIT COMMITTEE.—J. B. Haig, Esq., in the chair. At this Meeting there were several prizes offered. In Class A, for the best collection of Grapes, there were two entries, the first from Mr. Meredith, of Vine Cottage, Garston, near Liverpool, was a very fine collection, consisting of twenty-one varieties, and grown as Mr. Meredith always grows them. In such a collection we can have only space to notice a few particularly, and of these we could not but admire the bunch of Muscat Hamburg, which was large and well set, and the flavour most delicious. Every season seems to add fresh honour to this most delicious of Grapes. Alicante was large and well set, the bloom on the berries thick and solid-looking. Trentham Black was also fine both in appearance and in flavour. Mr. Meredith showed in this collection a seedling called Garston Seedling. It is an immense bunch, as might have been expected from the cross between Syrian and Muscat of Alexandria. The berries are large, white, and with a fine rich flavour, which in the bunch exhibited was not fully developed, from being as yet rather unripe; but when this Grape is fully ripened we have no

doubt but that it will prove to be the best-flavoured late White Grape yet in cultivation. It surpasses both Trebbiano and Calabrian Italin in this respect. Mr. Meredith was requested to send it again later in the season. For this collection of Grapes Mr. Meredith received the first prize. The second prize was taken by Messrs. Lane & Son, of Berkhamstead, who also exhibited fine bunches of twenty-three so-called distinct varieties; but as Frankenthal, Black Hamburg, Esperione, and Pope Hamburg were all the same, and Mill Hill and Champion Hamburg were also synonymous, that reduced the number to nineteen. These had all been grown in an orchard-house, and though fine in appearance were infinitely inferior in flavour to those of Mr. Meredith.

In Class B, for the best dish of Cox's Orange Pippin, the successful competitor was Mr. Charles Turner, of Slough. Mr. Rivers, of Sawbridgeworth, also sent specimens of this variety not for competition but comparison, and though they were larger and of a finer colour than Mr. Turner's, they could not approach them in flavour.

In Class C, there were no entries with the exception of Mr. Spivey, whose specimens were not the Golden Reinette.

In Class D, Mr. Spivey, gardener to J. A. Houblon, Esq., of Hallingbury Place, Essex, took first prize with Pine Apple Russet, fine specimens of that variety.

A seedling Grape was sent by Mr. Ross, gardener to C. Eyre, Esq., Welford Park, near Newbury, but it was not sufficiently distinct from Black Hamburg to be considered a different variety.

Messrs. Lucombe, Pince, & Co., of Exeter, exhibited a bunch of Mrs. Pince's Muscat, a Black Grape producing a large, long, well-shouldered bunch with oval berries, the flavour of which is very rich and excellent, and with a distinct Frontignan flavour. This was considered a Grape of first-rate excellence and received a first-class certificate.

Mr. B. S. Williams, of Paradise Nursery, Holloway, sent a splendid bunch of the Royal Vineyard Grape, which received a first-class certificate at the November meeting in 1862. The bunch exhibited on this occasion was much finer than that shown last year, and was about 15 inches long, tapering like that of the Black Prince. The berries were large, quite round, and of a pearly look; the skin is so thin, and the flesh so hard and crackley, that it is eaten like a Bigarreau Cherry, skin and all. This is said to be a late-hanging Grape, and if so it will be a valuable one.

A specimen of the fruit of Hurst House Pine Apple was sent by Mr. Page, gardener to Wm. Leaf, Esq., of Streatham, which weighed 7 lbs., and which was considered a very good specimen.

Mr. Alves, gardener to A. Hamilton, Esq., of Southborough, Kent, sent a Persian Scarlet-fleshed Melon of large size, ribbed and of a very dark bottle-green colour. The flesh was, unlike Scarlet-fleshed Melons, very tender and melting, remarkably juicy, and rich; this is by far the richest-flavoured and best of all the Scarlet-fleshed Melons we ever tasted. It was very justly awarded a first-class certificate.

Mr. Standish, of Ascot, sent fruit of a new Fig which came from the south of Europe, of most delicious flavour. The fruit is said to grow as large as the Brunswick, and the tree is a great bearer. This received a first-class certificate.

Mr. Terry, gardener to Lionel Ames, Esq., the Hyde, St. Albans, sent four dishes of Currants which were in beautiful condition, and which reflected great credit on Mr. Terry's management. They were as bright and fresh as we are used to see them in July. These received an extra prize.

George Wilson, Esq., of Gishurst Cottage, Weybridge Heath, sent magnificent specimens of the Melon Apple, Northern Spy Apple, and Chaumontel Pears. These were grown in an orchard-house, and both in size and appearance looked like tritons among minnows. They were remarkably fine and were awarded an extra prize.

Messrs. Paul & Son, of Cheshunt, sent a Seedling Apple called Cheshunt Pippin, which is said to be a long-keeping and excellent culinary Apple. It has much the appearance of Cellini, but not the flavour. Mr. Paul was asked to send it again, and in the meantime the Secretary was requested to have its culinary properties tested.

Mr. E. Holliday, gardener to J. Alleson, Esq., Friar's Place, Acton, sent very fine specimens of Cluster Golden Pippin and Blenheim Pippin.

TELLING BEDS OR FLOWER GARDENS.

THIS of all seasons of the year is the most important to the gardener in matters of flower-gardening, as now is the time he should be closing propagation for the coming year, and it also becomes necessary that he should strictly examine his beds to detect any fault of arrangement, as well as to decide by what change of planting, and by the introduction of what novelties he may keep alive the interest of his employer, and of visitors in them. No matter how perfect the arrangement may be in colouring, nor how faultless the design, it is requisite that each year should show a change, otherwise the eye wearies, and one half of the interest and pleasure is lost.

Thinking that it might be desirable that correspondents should forward sketches of the flower gardens under their charge, together with a plain description, I forward a drawing of mine. It does not contain much that is new; for, from the situation lying open to cutting north-east winds, the hardness of all novelties requires to be severely tested previous to their adoption, and to be grown to procure stock where the gardener's knife can be used more freely than is generally agreeable to the lady portion of our employers in the early part of the season. I am always obliged for advice, ever willing to learn. Should you see anything objectionable in the arrangement, to point it out will oblige.—O. BALTON.

1, Centre basket, 2 feet high, Flower of the Day, edged with *Lobelia periclosa*; bed Tom Thumb Geranium, edged with Flower of the Day.
2, 3, 4, 5, Verbenas.
6, 7, Tom Thumb Geranium, edge Alyssum.
8, 9, Trentham Rose Geranium, edge Alyssum.

10, 11, *Calceolaria Golden Fleece*, edge *Perilla nankinensis*.
12, 13, Trentham Rose Geranium, edge *Cerastium*.
14, 15, *Poule de Neige* Geranium.
16, 17, Flower of the Day.

[We like the plan of your garden quite as well as the planting. 1st. There seems to be no gradation as to height. There is Tom Thumb Geranium for centre; two Tom Thumb and two Trentham Rose beds for wings, and then Trentham Rose for ends. The ends, 12 and 13, being the smallest figures, tall plants would be out of place there. Now, though the garden would look best if the beds were nearly on a level, still as the centre bed is to have an elevated centre, in the shape of a basket, we would have a tall instead of a dwarf scarlet there, and, therefore, would use Punch Scarlet, or better still, Beaton's Stella for 1; and the sides for variety we would have *Cineraria maritima*, or *Centaurea candidissima*. Then you might make 6, 7, 8, 9, Trentham Rose, with Alyssum, or two of Trentham Rose and two of Rubens crossed, and the outsides, 12, 13, might then be Tom Thumb, with *Cerastium* for an edging.

2nd. The four quarter-moons round the centre, 2, 3, 4, 5, would be passable with mixed Verbenas of strong growth; but if three colours are to be distinct in each, they will be drowned by the masses in 1, 6, 7, 8, 9. Then, besides, we do not like the arrangement of having three bands in these beds—red, white, and purplish-blue. It is just the old story of having a white-bodied phaeton with one wheel

red and the other purple. I have seen lots of such beds this season, and the owners have a perfect right to plant them as they will. This style of ornament is also getting popular. We would just advise you to try a similar style with some pretty female friend of yours, who had a rather pale complexion, by sticking a long wreath of Violets on one side of her face, and an equally long wreath of pink Roses on the other side. Or try what the effect would be with a long purple pendant in one ear, and an equally long golden one in the other. If you are satisfied we have no argument to offer against your decision, even should you resolve that your fair lady should appear in company with one booby of the loveliest red, and the other of the most beautiful purple. If these four beds are to be ringed, then we would prefer the centre to be white, and the outsides purple all round.

3rd. Though not in the list, you give an edging of blue to 14, 15, 16, 17. That, in connection with the purple round the quarter-moons, would lead us to change the planting of 10 and 11, by placing *Perilla* in the centre, and a broad band of the *Calceolaria* round it. We think that heights and colours would then be better regulated, but do not be led by our opinion.—R. F.]

TRUFFLES AND TRUFFLE-BEDS.

In the south of France Oak coppices are not grown for the sake of the wood, but because the black Truffle, which is so highly prized by the lovers of good eating, is chiefly to be found among the roots of that tree; and it there acquires an aroma which is wholly absent from Truffles growing among the roots of the Elm, Beech, Walnut, Chestnut, Lilac, and other trees.

M. Tulasne has carefully investigated the history of this underground fungus and produced a magnificent work on the subject. He divides the genus *Tuber* (Truffle), into twenty-one species, of which four are confounded under the name of the common or black Truffle. Two, the black Truffle proper, and the winter Truffle, ripen in autumn and are taken up during the beginning of winter. The former is the most highly perfumed, and that held in the highest estimation. Its surface is warty, and the interior is of a uniform black with a reddish tinge, and marbled with white veins, which become reddish when the fungus attains a greater age. This species is common in Italy, Provence, and Poitou, and is also occasionally found near Paris, and in England.

Black Truffle.

The winter Truffle is inferior in quality to that just described and always accompanies it. The flesh is white when young, and afterwards blackish and marbled with white veins.

Two other species come to maturity at the beginning of summer. One, called the Summer Truffle, common in Germany and the central districts of France, is covered with large warts, whilst its flesh is whitish at first, afterwards turning to a brownish colour marbled with white veins. The other, which is common in Italy, is of a greyish-brown, and the veins are extremely tortuous. Both of the above are also met with near Paris.

At Apt in the department of Vaucluse the Truffles are cut in thin slices and dried. In this way about 197 tons are annually exported.

To the four species already referred to must be added the white Truffle of Piedmont, which Napoleon preferred to the black kind. The others which M. Tulasne names are not edible.

Truffles are generally found in chalky or clayey chalk soils. Just as many aerial fungi only grow on dead wood, and that of a particular kind, so the Black Truffle is only met with among the roots of trees, and more especially the common and Evergreen Oak, and *Quercus coccifera*. It is among the roots of these trees that the Truffles are most abundant and acquire a perfume that makes them esteemed all over the world. If the trees are too large and shade the

ground too much the crop falls off, but it increases as the coppice grows.

Truffles increase like other fungi; when ripe they contain minute spores not exceeding $\frac{1}{16}$ th of an inch in diameter, and when the Truffle decays in the ground these produce white threads, or mycelium, like Mushroom spawn when running, and a fresh crop results.

Many prejudices exist, however, among Truffle-hunters. Some imagine that the Truffle is a natural excrescence from the roots of the Oak; others that it is the consequence of a puncture from a fly or some insect; and most believe that there are Oaks at the roots of which Truffles are met with, and other Oak trees which do not produce them. Such opinions are wholly wrong, for the Truffle is an underground fungus reproduced like others of its race, but only succeeding in calcareous soils and amidst the roots of trees, and among the roots of the Oak in particular. The rains of July and August encourage its growth and increase the crop.

Truffle-hunters had long observed that vineyards and arable land surrounded by stunted Evergreen Oaks were very productive of Truffles: hence M. Auguste Rousseau, of Carpentras, conceived the idea of attempting their cultivation. He sowed in a piece of sandy calcareous ground, about five acres in extent, a quantity of the acorns of the common and Evergreen Oak at the roots of which Truffles had been found. The sowing succeeded; at the expiry of eight years, in 1856, the late M. de Gasparin found that there was a yield of about 7 lbs. per acre, worth £1 18s. 4d.; but since then both the produce and the price of Truffles have advanced. At the present time M. A. Rousseau obtains an average produce of 46½ lbs. per acre, which at current prices is worth £12 12s. 6d. Deducting labour, rent, &c., we have £11 19s. 6d. as the nett produce of an acre of bad ground which has been fifteen years in Oak coppice. Few crops produce such a return with the investment of so little capital and labour.

Two interesting facts have been observed in M. Rousseau's Truffle-grounds; one is that the Truffles are more plentiful, more equal in size, and have a higher perfume when they grow at the roots of the Evergreen Oak than when found among those of the common one; the second fact is that the Truffles are always met with at the foot of those trees where they had been found in previous years. Such trees are always marked with a white cross, and the sow employed to find the Truffles immediately seeks them out and routs up the ground. The Truffle being found, she receives a tap on the snout, and some acorns or a Potato are thrown to her as a reward. Swine smell the Truffle through the ground; and some dogs can likewise be trained to hunt for it, but they confine themselves to pointing out the place where the Truffle exists, whilst the sow does all the work—discovers and routs it up. The person in charge must, however, be watchful, otherwise the prize will be immediately crushed between the sow's strong jaws, to open which by means of a stick a vain attempt is often made.

On an average from the 1st of December to the end of February £80,000 worth of Truffles are sold at Carpentras, from which they are sent to all parts of Europe. The communes of Bedoin, Blauvac, Monieuc, and Metrennes contain 6672 acres of Truffle woods let at £530 a-year. The coppices continue productive for twenty or thirty years, after which the ground from having been shaded and kept too dry is no longer favourable to the growth of the Truffle, but then the wood can be sold for firewood.—(ALFRED LEJOURDAN in *Revue des Jardins et de Champs*.)

THE GLADIOLUS QUESTION.

I HOPE we may look upon the question of pronunciation as now settled; for although I have great respect for Mr. Beaton, I do not think I should sit at his feet for the pronunciation of Latin. Nor am I inclined to agree with the notion that we must pronounce as gardeners have done. The flower is as a florist's flower comparatively new, and now that the bairn is fairly launched into the world, let it have its right name. A contemporary, I see, has, since this controversy begun, also given its opinion in favour of *Gladiölus*; so if the two great gardening papers will only hold to it, it may be considered as determined. Your correspondent, "S. D. S.," asks where I would put the accent.

On the first syllable, for as it is from *gladius* the stress would be there.

I do not think that light soils give an immunity from the disease, but I have been more strengthened in my opinion since I wrote. They have done well in Messrs. Carter's light soil at St. Osyth, and badly in one or two other places where the soil is heavy. Mr. Cattell suffered, I know, but not severely, and I am aware that his intelligent foreman, Mr. Heale, differs from my view of the case; still I am inclined to hold by my own opinion, and look forward to further confirmation of my views.—D., *Deal*.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

MICROSTYLIS BICOLOR (Crisp-purple-leaved *Microstylis*).—*Nat. ord.*, Orchidaceae. *Lin.*, Gynandria Monandria. "One of the most lovely of terrestrial Orchideous plants." Flowers yellow, but changing to orange; leaves purple, usually green-edged. Native of Ceylon.—(*Bot. Mag.*, t. 5403.)

SPHERALCEA ACERIFOLIA (Maple-leaved *Sphæralcea*).—*Nat. ord.*, Malvaceae. *Lin.*, Monadelphia Polyandria. Native of rivulet banks in North-western Australia. Flowered in a greenhouse at Kew, in June, but believed to be hardy. Flowers pale purplish-pink.—(*Ibid.*, t. 5404.)

ERANTHEMUM TUBERCULATUM (Warted *Eranthemum*).—*Nat. ord.*, Acanthaceae. *Lin.*, Diandria Monogynia. A most abundant bloomer. Flowers white. Probably a native of the South-Sea Islands.—(*Ibid.*, t. 5405.)

HEDISCUS HUGELII var. **QUINQUEVULNERA** (Five-wounded *Hugel's Hibiscus*).—A crimson spot at the base of each of the five petals suggested the name. It is a native of Swan River. This and *H. Wraye* and some others are only varieties of *H. grossularifolius*.—(*Ibid.*, t. 5406.)

CEROPEGIA BOWKERI (Bowker's *Ceropegia*).—*Nat. ord.*, Asclepiadaceae. *Lin.*, Pentandria Monogynia. Native of Caffraria, South Africa. Petals greenish-yellow, and reflexed like those of the *Cyclamen*.—(*Ibid.*, t. 5407.)

SARCOPODIUM PSITTACOGLOSSUM (Parrot-tongued *Sarcopodium*).—*Nat. ord.*, Orchidaceae. *Lin.*, Gynandria Monogynia. Native of Moulmein. Flowers yellow, tinged with green and striped with red.—(*Ibid.*, t. 5408.)

FUCHSIA *Pillar of Gold*, raised by Messrs. Smith, florists, Dulwich. Flowers crimson-sepaled and purple-cordoned. Leaves abundantly stained with yellow.—(*Floral Magazine*, pl. 165.)

PINKS, raised by Mr. C. Turner, Slough. *Rev. George Jenas*, white and crimson. *Lord Herbert*, white and lilac.—(*Ibid.*, pl. 166.)

PELAGONIUMS, raised by Mr. Hoyle, Reading. *Achilles*, "perhaps the most brilliantly coloured *Pelargonium* ever raised." Upper petals intensely dark with fiery margin, lower petals deep carmine; throat white. *Artist*, dark upper petals with rosy edge, and lower petals also of the latter colour.—(*Ibid.*, pl. 167.)

GREENOVIA AUREA (Golden *Greenovia*).—Native of Madeira. Allied to the Houseleek. Flowers yellow.—(*Ibid.*, pl. 168.)

RHODODENDRON, *Standish's Perfection*, trusses of bloom fine, each blossom of great substance; colour lilac-rose softening into white.—(*Florist and Pomologist*, ii., 137.)

PLUM, *Belle de Septembre*, "one of our handsomest late Plums." Fruit oval; skin bright red, with a delicate violet bloom. Flesh yellowish-white, juicy, sweet, and somewhat aromatic. The tree is an abundant bearer.—(*Ibid.*, 144.)

RAPID GROWTH OF BROCCOLI, &c.

HERE (Isle of Wight), we grow most of our Winter Greens, Broccoli, &c., in a small field adjacent to the premises. We do not plant these things out so early in the season as many do, and especially those in the northern counties who are obliged to do it at a much earlier period in summer. However, what I more particularly wish to notice at present is, the very quick growth which these vegetables have made within a month. We generally have the ground worked and well dunged early in June. The weather this summer being quite an exception, after we had the ground all ready

we had to wait a short time, expecting to be favoured with a shower, to get them planted out. There came a shower towards the close of June; we planted all out. The plants were strong, having been planted out singly from the seed-beds into newly-dug ground as soon as they could bear this operation. The ground in the field being well worked was nice and loose, and warm so far as it had been moved. We planted them in as deep as they would allow. They remained stationary for two months, or rather they went back for a time, as they became less. Upon the 19th of August a change came over the weather, rain fell for some days to a large amount, and for nearly three weeks we had more or less rain nearly every day. For some time the dull and cloudy weather accompanied by the rain was quite a relief to all vegetation. In a few days after the rain on the 19th of August our Broccoli, &c., began to have a much greener appearance, and from the 24th of August for three weeks following, the leaves of the Broccoli grew at the rate of fully 1 inch in twenty-four hours. Many of the leaves are now over 2 feet in length. Three weeks ago they were not more than a hand-breadth, and with anything like a fine autumn we shall yet see splendid Broccoli. We had a number of Broccoli last spring 3 feet in circumference.—G. LAWSON.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Now is a good time for draining any part of the garden in want of it; to replant the Box and other edgings, or to mend gaps where it is not necessary to remove the whole; to dig gravel for new walks, or for repairing the old ones; to trench and drain ground newly taken-in, and every spare piece in the garden, choosing suitable weather for these operations. *Asparagus*, it is recommended to those who intend making new beds in the spring to prepare the ground immediately by digging-in and well mixing a large quantity of dung and leaf mould with the soil, the ground to be slightly forked-up in the spring, and the beds to be formed and planted. *Broccoli*, the plants that are now getting too luxuriant may be checked by laying. *Cabbage*, secure the supply of the best Red for pickling while they are sound and good after they have had sufficient of frost to stay their natural colour. *Cardoons*, tie up for blanching when the leaves are quite dry. Twist haybands round so that the earth may not come in contact with the leaves when earthed-up. *Cauliflowers*, some of the plants of suitable size and age to be potted and placed in Melon-pits, frames, turf-pits, or temporary pits made with a few stakes, and interwoven with evergreen boughs, firze, heath, fern or straw; they may then be covered when frost is likely to occur, with pea-baulm, evergreen boughs, mats, or anything that is convenient laid on cross-poles or sticks. A quantity may also be placed in warm sheltered corners or borders; and if taken up with balls of earth and temporarily sheltered as advised, both *Cauliflowers* and *Cape Broccoli* can be secured in succession through the winter. *Onions*, the small ones should also be thought of for pickling while they remain good. *Peas*, warm dry borders and banks should be prepared for an early crop, and also for Broad Beans, so that time may be allowed for exposure to the influence of the atmosphere. See that the Pea and Scarlet-Runner sticks are snugly tied in bundles and stacked away tidily in a dry place. *Sauys*, if any strong plants of these or of the varieties of Kale should be left in the seed-beds, by all means put them out thickly, and those who have spare ground should still continue to put out *Colworts* and *Cabbage* plants. *Turnips*, those who are fond of Turnip-greens at an early season, if they have any overgrown bulbs left in their beds should at once collect them, and plant them a foot apart in a warm quarter or sloping bank. Hoe and stir amongst all growing crops in suitable weather, and collect all dead and decaying leaves.

FLOWER GARDEN.

In some localities the cold frosty nights we have lately experienced must have greatly damaged the appearance of the more tender kinds of plants, and such as are to be saved should be removed at once. Proceed, therefore, with potting such plants with as much despatch as possible, and if practicable a little artificial heat should be applied to help

them to root before winter. Lawns, to present anything like neatness, will now require daily sweeping. Well clean gravel walks for the winter, and afterwards let them be well rolled in order that the water may pass freely off the surface. As soon as the bloom is well off the Dahlias they should be cut down, the roots taken up and dried, and put away perfectly secure from frost. Auriculas to be cleaned and put into winter quarters. Take care there is no drip upon them. Prepare the ground for and plant Tulips, Hyacinths, Crocus, &c. Hyacinths for forcing to be potted; also, double Tulips, Narcissus, Jonquills, Iris, &c. Cuttings of China and other Roses to be potted and put into a cold frame. Chrysanthemums in pots to be removed into the greenhouse. Give abundance of air to keep them from drawing. *Tigridia pavonia* growing in borders to be taken up. All operations of planting, relaying turf, and border-making to be actively proceeded with.

FRUIT GARDEN.

Peach and Nectarine trees will now begin to cast their leaves, and it will be an advantage slightly to brush them upwards with a small birch or long whisk to clear the leaves from the branches. Keep them closely nailed to the walls, or they will be liable to be broken by the wind. Gooseberry and Currant trees may be pruned when the leaves have fallen. Keep the centre of the trees open for the free admission of sun and air. Fruit trees of all descriptions to be planted as early as is convenient, to establish them in their new situations before severe weather come. Be careful in collecting the late varieties of Pears and Apples, to have them wiped and regulated after sweating. The Medlars and Quinces to be collected in good condition. To select perfect Walnuts for storing it is advisable to immerse them in water after the husks are taken off, and all that are quite perfect at once sink to the bottom, while the imperfect fruit float on the top: even those that have the least deficiency in the kernel will float. Those that have sweated should be well cleansed by being placed in a dry sack and shaken from end to end by two persons, the friction will clean them perfectly.

STOVE.

Finish repotting; every plant that requires it should now be shifted. Always use clean pots and plenty of drainage. Prune in all climbing plants. Ferns to be separated and repotted. Cacti, Euphorbias, and other succulents require less water now. Air to be given in fine weather. A little fire heat will be necessary occasionally to expel damps.

GREENHOUSE AND CONSERVATORY.

Here, also, the potting must be finished as early as possible. Let Azaleas be tied into form as soon as can be done. It may be useful to state that everything in the nature of charcoal, whether wood, weeds, or the clipping of hedges, &c., which is susceptible of being charred or converted into charcoal, will be found of great benefit in its application to the soil. It is a substance that has the power of absorbing both moisture and ammonia from the rain and the air, and by that means is enabled to impart amazing vigour to the plants when it is used as drainage or mixed in small quantities in the soil.

PITS AND FRAMES.

All plants in this department to be put in order for the winter as quickly as possible. Those that are well established to be placed in their winter quarters at once, giving the most valuable ones the best places; but those that are not well rooted to be kept close for a few weeks longer. The plants of Neapolitan Violets to be shifted into pots or planted in a well-raised bed of light sandy soil sheltered from rain. They require plenty of air, to be kept moderately dry, and just secured from frost. The bed may be made with faggots, and lined round with loose litter, or with half-spent hot dung when the weather gets frosty.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

EARTHED-UP Celery in the mode detailed, so as to keep a good supply well blanched. As there is now little danger of much dryness, gave the later crops a little earthing-up, with a fair allowance of ashes to keep slugs, &c., at a dis-

tance. Noticed some half a score of plants with the leaves rather blanched and withered. Were afraid it was the grub, so difficult to get rid of when once it takes possession, but found it was the result of using some sewage water rather strong over the leaves. This was entirely owing to the carelessness of the waterers. It is, therefore, a good plan when watering with manure water at the roots, to follow with clean water overhead. Roots will stand an amount of strong waterings after raking them through earth, which no foliage could receive for any time and live. Made up a few more blanks in the Cabbage-quarter, and planted-out a few Savoy, which even in a shady place will come on stronger than those planted-out from spring sowings in the best position. Cleared away some more Peas and Bean haulm. Find there are some still very good out of doors. Gathered some of the best Parsley seed, and cleared all the tops away, being undecided whether to leave a portion of the old roots or not, as the spring-sown is strong enough, and a piece is sown so as to be sheltered from snow and frost. We have had to gather this indispensable from under 2 feet of snow, but it is as well to avoid the necessity. Hoed amongst winter Onions. If there is a frame or pit at liberty, it is a good time to lift half-grown Lettuces with balls, and plant them about 10 or 12 inches apart, and being watered now, and the surface soil kept dry afterwards, the Lettuces will keep and grow all the winter. These are far before Endive for salads. Covered up more of the latter. Took up part of Carrots, Salsafy, Beet, &c., as huge roots of the latter, however dark red, are generally objected to. Gathered most of the ripe Chilies and Capsicums, chiefly for Cayenne pepper. The greener ones will do for pickling. Will leave some more to ripen. We may learn something fresh every day. We used to think that if the large Capsicums were as hot as the Chilies, they ought, bulk for bulk, to make as good Cayenne pepper, and so they may in the pepper of the shops, where, no doubt, all is ground down together, and some red colouring matter used. In most gentlemen's houses we find, however, that the outside of the seed-vessels only is used, and that after being much dried: hence the superiority of the Chilies for this purpose. We should think, however, that the seeds would, but for the colour, make as fine pepper as the rind. Gathered the last of the Tomatoes for sauce, and regulated Cucumbers most likely for the last time, as we have given over keeping up a regular winter supply.

FRUIT GARDEN.

Proceeded with fruit-gathering as the weather would permit, and as the nights are frosty pulled those Apples and Pears most exposed first, as the less they are frosted the better. Will cut the roots of some trees as soon as the fruit is gathered, and will mulch others that were so cut last year and are as yet rather weak in the buds. Transplanting and moving cannot take place too soon now, and fresh plantations will thrive all the better the sooner they are made.

The different modes of planting fruit trees have recently been referred to. The materials should also be considered. Pure fresh loam about the roots will in general answer better than any amount of manuring. Light sandy soil and a little leaf mould close to the roots will encourage fresh root-action; but care should be taken that the leaf mould is well decomposed and has no spawn of fungi imbedded in it, or the advantages may be more than counterbalanced by the disadvantages. In cases where half-rotten leaves have been used we have known the roots suffer greatly, in fact to be next to killed, by the spawn of fungi of many kinds. If taken in time fresh lime is a good remedy. We have hardly met any kind of fungus that likes quicklime. We have known Mushroom-beds ruined with a watering of lime water to kill the slugs that attacked the Mushrooms. It would have been better to have trapped them with buttered Cabbage leaves, brewers' grains, or hunted for them at night with a lanthorn. There is no method like the last for catching huge snails that make nothing of clearing off several large Mushrooms. A dark night and a lanthorn are almost the only means by which these large fellows can be caught. At times they find their way into fruit-rooms, and the same mode of finding them must be resorted to or they will do great mischief, and if there is one favourite fruit in the room, that they will seize on as their favourite morsel.

Gave fire to late houses of Vines to prevent damping and extra air in fine sunny days: left air on all night, though not much, and will only close up in a severe frost. Repotted a few Strawberry plants from 2s. to 3s., as we thought we had rather too many in small pots. Went over all the lot, weeded them, cut laterals, and shortened any leaves turning brown. We will expect more to brown presently, but will leave them until having time for protection. Gathered pretty well the last of the Melons, and will let them ripen in the houses, as we now want the room; and unless the weather is fine and bright, Melons are rarely of much use in the end of October. Will lay Strawberry-pots on their broad sides if the bad wet weather continues. Put old sashes over part of late Vine-border, and straw covers beneath to throw the rains past them. Gathered fruit in dry sunny days, as then it can be stored in wet days.

ORNAMENTAL DEPARTMENT.

Regulated the flower-beds, which are yet passable. Rolled walks and lawns. Swept leaves from latter, which is like washing a blackamoor white, and would require more labour than we can supply, if done at all, every day, or second day. Took up a few things out of the beds, as Cloth of Gold and Golden Chain Geraniums, to be followed with a few of other variegated sorts. Took up also some lilac Lobelias and others of various colours—one much like the old bicolor and with some resemblance to Paxtoniana. Gathered a few seeds in dry days. Tied-up what the winds had blown down. Cut over some Humeas getting dingy in colour. Prepared a pit with a little bottom heat for the above variegated Geraniums, where the pots will be plunged but the heads kept airy and dry. Went on as occasion offered with Calceolaria cuttings, adding four more lights to the previous ten, which we suppose must do, and filled about a dozen of the moveable wooden boxes with Calceolaria amplexicaulis, the only one that will not stand so much as the rest of damp and cold, and therefore put in boxes that they may be moved where there is the least dry heat in continued dull frosty weather. Thinned creepers in conservatory, and took most greenhouse plants under cover. Heath and Epacris may still remain in cold pits, to have all the benefit of the sun in fine days, and abundance of air at other times, unless when there is frost; but even they will do as well in an airy part of the greenhouse. Gave more room to young Pelargoniums, and will soon have to repot a lot that was cut down rather late and which is now breaking nicely. Moved all Ferns, stove plants, &c., out of the lateinery and placed them in one just cleared, until the small stove-house undergoing alterations is prepared for them, when many things will require fresh surfacing if not fresh potting; and Stunbopeas, &c., will need fresh doing-up at the sides of the baskets, &c. The climbers have been laid down and covered with mats in the meantime, till the house shall be ready for them.

As a preparation for all departments, have collected—or rather, perhaps it would be truer to say, carried off—some soil from the sides of highways and byroads, for there are now so many new rules about roads and surveys that it is almost as difficult to take a load from such places as to carry off a handkerchief full of earth from one of the London parks. Given a worthy employer that would not on any account have a sod taken from his park or other pasture, and what is a poor fellow to do when surveyors are upon him if he touches the sides of the highway, even though he is doing good to the road all the time? Well, we know something of the effects of a soft answer and courteous manners; and to all young friends who are in any such troubles we advise a free use of the latter weapons instead of a stern unbending assertion of customs and rights, and all the rest of it. We have thus managed to take a few loads of fibry turf from a roadside, and it will be built into a stack 1 yard wide, thatched with long turfs of itself, and valued almost as if it were gold.—R. F.

COVENT GARDEN MARKET.—OCT. 10.

The market continues well stocked with all kinds of fruit and vegetables, and heavy supplies of the former are coming in from abroad. There is scarcely any alteration from last week's quotations. The supply of English Melons is falling off. Late Plums are plentiful, and so are Pears. These consist of Louise Bonne of Jersey, Marie Louise, Gansel's Bergamot, Brown

Beurré, and Duchess d'Angoulême, the last-named being very good. Apples chiefly consist of Ribston, Warwickshire, and Golden Pippins, and King of the Pippins. The best Cobs are bringing 60s. per 100 lbs., but inferior samples may be had at 55s. Of Potatoes there is still a very heavy supply. Cut flowers consist of Orchids, Pelargoniums, Asters, Dahlias, Roses, and Magnolias.

TO CORRESPONDENTS.

“We request that no one will write privately to the departmental writers of the ‘Journal of Horticulture, Cottage Gardener, and Country Gentleman.’ By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.”

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

STEAM PIPES (*A Subscriber*).—We fear that common drain-pipes with open joints will not answer to convey steam as you propose. We should employ four-inch hot-water pipes, for we are certain that they would cost no more than making a flue to put the drain-pipes in, which is quite unnecessary for top heat. Pot drain-pipes 4 inches in diameter, with the joints cemented, will answer better than drain-pipes. Your other arrangements are unique; but as you say nothing about ventilation, we are obliged to give you a hint that Cucumbers will need an airing daily in mild weather, and be none the worse for a little fresh air at all times if you have heat enough. You should have at least two four-inch pipes for top heat, but one is ample for bottom heat. We need not tell one more conversant with steam than ourselves that the pipes must be laid so that water can drain from them. We are much pleased to see means adopted to utilise the waste steam of manufactories, for it is evident that many garden structures might be economically heated in the way you propose. We know of some that are heated by the steam from an engine, and they answer perfectly.

WINTERING EMPEROR AND BRUMPTON STOCKS (*Liverpool*).—We would advise you to pot sufficient of the Emperor and Brumpton Stocks and winter them in a cold frame, or some place where protection can be given in severe weather, for, though your plants stood last winter in an exposed situation, it is just probable the forthcoming winter may be as severe as the last was mild. The beginning of March is quite early enough to plant them in the beds; but will not their flowering interfere with the planting of the summer occupants of the beds?

APHELANDRA LEOPOLDI CULTURE (*Mrs. W.*).—It is a very ornamental stove plant, but by no means rare. Cuttings of the young half-ripened shoots strike freely in a compost of peat and loam half, silver sand half, placed in small pots and plunged in bottom heat ranging from 75° to 80°. The cuttings need potting when struck, a compost of one half peat and the other half turfy loam, with a liberal admixture of silver sand, suiting them. In future seasons it will require potting in early spring and occasionally stopping or cutting back the shoots to keep it dwarf, as it is apt to become straggling if not stopped. An ordinary stove temperature suits it, or any place with abundance of light where the temperature does not fall below 55° in winter.

EVERGREENS FOR A SCREEN (*L. J. R.*).—We know of no evergreen trees except Yews, Firs, and other coniferous trees that attain any size quickly, and even these grow no faster than Evergreen Oaks. We should plant a row of Lime trees and face them with evergreen shrubs, or have a mixed border of deciduous and evergreen trees and shrubs, employing Lime, Plane, and Elms, and Arbor Vitæ, Laurels Portugal and common, Rhododendrons, Hollies, &c.

SOWING PANSY SEED (Leighton B.).—The middle of September is late enough to sow Pansy seed, the beginning of that month being the best time to secure good plants for bloom next season. Seed may be sown in early spring in boxes, and a little bottom heat afforded until the plants appear, when too much air cannot be given. The plants will thus be hardened-off, when they may be pricked into the beds where they are intended to bloom. They will flower towards autumn. September-sown Pansies flower earlier than spring-sown, and are finer. We know nothing of Good Gracious Pansy seed.

MOLDS (W. R.).—They uproot your Celery in searching for worms and other insects which harbour in the manure at the roots of the plants. We know of no mode of getting rid of them except by trapping.

STRAWBERRIES FOR FORCING (M. B.).—Your pots of Strawberries put on a high shelf in the greenhouse for forcing may be kept dryish, but not dry, for if too dry you will cause the flower-buds to perish, even when the outside leaves seem to stand it. You will do the same thing if they are kept very wet. Before you started them they would be better plunged in a cold pit or frame.

DIELYTRA OCCIDENTALIA CULTURA (A. R.).—The difficulty is to grow this plant at all without flowering it. It requires a moderate light and free soil, and all the sun and air practicable. The roots do not do well when planted deep, a few inches below the surface being deep enough. The roots require taking up occasionally, and their quantity reduced, or they very soon come rank and flower very little or not at all.

SOIL FOR MITHARIA COCCINEA (Gatley).—Peat half, turfy loam quarter, and silver sand the remainder. A cool greenhouse temperature suits it, abundance of water when growing, and a rather moist atmosphere, but the shoots cannot have too much light and air when the growth is made. The roots require confining in a rather small pot for the size of the plant, and to be kept dry during the winter, but not so as to cause the leaves to fall.

TIGERROSES AFTER FLOWERING (S. R. E.).—They do not flower well the second season; but if you choose to try them you may take the bulbs out of the soil and keep them in a cool dry place until planting time, or you may keep them in the pots with the soil dry, repotting them in spring.

OLEANDER CUTTINGS (Idem).—Spring if there be any half-ripened cuttings on the plants, or any time when there is. They strike freely in water, and so do many other plants.

FERNS UNDER A NORTH WALL (A Lover of Ferns).—You could not have a better place; but we cannot tell you how to form the rockery, such being more a matter of taste than anything else. It may be formed of stones, and roots of trees, and if these be placed so as to leave some good-sized crevices between, and if the soil beneath be loosened, and if with the crevices filled with loam and cocoa-nut dust in equal parts, there is nothing to hinder your Ferns doing well. You will plant them so that the tall growers will be at the back and the dwarf in front. The border is narrow, but you will get over that by making the rockery high at the back against the wall. The rockery will best harmonise with the ribbon-border by being regular in outline. Our "Fern Manual" would further assist you.

CLIANTHUS FOR BEDDING (Leighton B.).—*Clianthus puniceus* and *C. magnificus* are hardy, or nearly so, against a south wall. It might be either of these you saw against a wall or trained round sticks in a bed, or it might be *C. Dampieri*, but which we do not profess to know. Any or all of them require sowing in spring in sandy peat and loam, growing on in a cool greenhouse or cold frame until established, and kept growing freely through the summer, or planted against a wall at once. Plants for beds, we should say, will need wintering in a greenhouse, and we are pretty certain the flowers must be formed or forming on the plants, or they will not flower at all outside. You do not say where you reside, and that hinders our speaking decidedly, for there is the difference of a greenhouse between the south and north. *Clianthuses* may do in the south outside, but in the north they do no good.

TREES FOR THE SEA-SIDE (H. C. S.).—Maple (*Acer campestre*, *A. pseudo-platanus*, and variegated); Horse Chestnut; Beech (*Fagus sylvatica*, *asplenifolia*, *pendula*, and *purpurea*); Lime (*Tilia europaea*, *alba*, *pendula*, *europæica*, *laciniata*, and *parvifolia* aurea, and *pyramidalis*); Elms (*Ulmus americana*, *campestris*, *montana*, and *viminalis*); Oaks (*Quercus Cerris*, *fagifolia*, *flex*, *nigra*, and *rubra*); *Juglans regia*, *laciniata*; Tulip Tree; *Platanus acerifolia*, and *occidentalis*. The above are trees. *Berberis* of sorts, *Arbutus*, Box, *Aucuba japonica*, *Cotoneaster*, many sorts, *Thorn*, *Laurels*, *Ribes*, *Sorbus*, *Viburnum*, *Lilacs*, *Spiræas*, *Hollies*, *Azaleas*, and common *Rhododendrons*. We have seen most of these by the sea on the east coast doing moderately well.

PEARS FOR ESPALIERS (Idem).—*Louise Bonne* of Jersey, *Colmar* d'Étè, *Bon Chrétien*, *Beurré Superfin*, *Alexandre Lambré*, and *Gansel's Late Bergamot*.

CALCEOLARIAS (J. Whitehead).—We never recommend tradesmen. If you write to any of the chief nurserymen and ask them to send you a catalogue of their *Calceolarias* you will be able to select for yourself.

LILIUM LANCEFOLIUM REPOTTING (A Subscriber since 1856).—If your three bulbs were only planted last year, in pots 11 inches by 13 inches, they will do one more year without further removal. Had your pots been less we would have said, *Repot*. We have adopted both ways, and found so little difference, that unless the bulbs require separating we let them remain two years in the same pots. Your Apple is the *Gloria Mundi*. Graft it in March on any Apple tree, or on stocks of the wild Crab.

GRAPE VINES FOR A NEW HOUSE (G. A., Beardmore).—As you do not mention whether you want the Grapes early or late, we suppose the latter, and would recommend the seven Vines you propose to consist of three Black Hamburgs, one *Wet's St. Peter's*, one *Lady Downes* Seedling, one *Alicante*, and one *White Grape*, as Sweetwater. If, however, you contemplate forcing early, you may have the same number of Black Hamburgs, but you might substitute *Barbarossa*, *Black Lombardy*, and *Mill Hill* Hamburg (a distinct one from ordinary Hamburgs), for the other Black ones, and you might try one *Muscat* of Alexandria. We often see it do well in a warm house, and we doubt not it would do so with you.

CHANCELLOR PEACH (J. Hawkins).—This variety is thus described in Dr. Hogg's "Fruit Manual":—"Fruit oval, large, pale yellow, dark crimson next the sun. Suture well defined. Flesh firm, pale yellow, very deep red at the stone, sugary, rich, and vinous. Stone oblong. Flower small. Glands kidney-shaped. Middle of September. Its synonyms are *Edgar's Late Melting*, *Nollette*, and *Steward's Late Galande*."

VINE-BORDER (R. G. B.).—Although the turf is green it will not be detrimental. Chop it small and mix it well with the rest of the compost. We should roast—that is, char it a little before so doing.

HARDY GOOD-FOLIAGED CLEMATIS FOR A TAEILLIS (An Edinburgh Subscriber).—We fear it is difficult to have both good foliage and pretty flowers on a Clematis. It would, therefore, be better if your place will allow of it, to have some other evergreen creeper mixed with the Clematis to give appearance in winter—say, for instance, a *Cotoneaster*, of which there are several varieties, and they are all hardy. The prettiest and best Clematises we know are *C. montana*, *C. vitalba*, *C. lanuginosa*, *C. azurea grandiflora*, and *C. Sieboldii*, with some tenderer varieties, one called *Sophia* being very fine. Clematises, however, rarely look well all the year, so that it would be better as above to have another plant to succeed them in winter.

TWELVE CAMELLIAS (T. Smith, Brixton).—*Comtesse Lavinia Maggi*, *Sarah Frost*, *Duchesse de Berri*, *Mesta rosea*, *Countess of Derby*, *Princess Frederick William of Prussia*, *Cup of Beauty*, *Montrossi*, *Saccaa vera*, *Princess Bacciotti*, *Roi Leopold*, and *Marchioness of Exeter*.

MUSHROOMS (A Lover of Mushrooms).—No mere description can enable us to point out the poisonous from the wholesome fungi, and to be an uncertain guide is a character we shrink from. Those who eat Mushrooms without having seen them, or without having them examined by a competent person, choose to run the risk, and must abide the consequences. Dr. Badham's book on "British Edible Fungi" with coloured plates, is a good authority.

HEATING A CUCUMBER-HOUSE (Her.).—We have no faith at all in your succeeding by taking the flue-pipe at once so much below the level of the boiler. You had far better have a boiler and furnace sufficiently sunk for that purpose, or raise the floor of the house sufficiently to have all the pipes above the boiler. For early Cucumbers you would find this much better than depending on a kitchen fireplace. For such a house, 19 feet at back and $2\frac{1}{2}$ in front would be good elevation. Part of the top glass should move and have ventilators in the front wall.

WALL PEAR TREES (Pteris).—We would recommend you to plant *Pears*. *Red Doyenné*, *Baronne de Mello*, *Beurré Diel*, *Knight's Monarch*, and *Marie Louise* would all do. (*L. G.*)—You cannot do better than select from those you mention. *Winter Nelis*, *Joséphine de Malines*, *Beurré de Rance*, *Beurré Serckmans* are what we would select from those you mention.

HEATING A VINERY (Omega).—We would allow the present Vines planted outside to remain, if they are at all in good order. Those in the proposed hothouse part could be taken down and kept in the front, protected, but the glass inside, so as to have a hothouse in winter if desirable whilst the Vines were resting. 1. The four-inch pipe all round will be sufficient for the small greenhouse, as far as keeping out frost in cold weather is concerned. 2. This one-inch pipe all round will not be sufficient for heat in the hothouse department, and we would alter the arrangement, so as to take two flow-pipes round the front of this part, cross with one pipe at the end and make the back pipe the return-pipe, so as to heat this house independently of the greenhouse. Take the flow-pipe round the front of the greenhouse connected by valve or tap, to be opened when necessary. 3. Having pipes front and back you might have a shelf of 2 feet over them, and $2\frac{1}{2}$ feet from the floor, which would do for Vines in pots, or anything else you particularly wanted. This with a passage all round of 2 feet would give you a bed of 7 feet in the centre, and beneath that you could have a tank of 6 or 6 feet, divided in the middle, with a depth of from 4 to 5 inches. The bed above it might be from 15 to 20 inches. 4. The tank may be made on the floor, if solid it ought to be as high as the pipes, or it must be made watertight on the rear and growing Vines in pots, for numberless purposes—such as rearing and forwarding lots of Asparagus, Sea-kale, Rhubarb, &c., in winter. 5. Were it ours we would have two or three four-inch pipes below the bed, and have no tank, surrounding the pipes with rubble. 6. If the economical end of your house, we would take a flue from a chimney close to the boiler-end through the bottom of the proposed bed and the furnace beneath the boiler through the bottom of the proposed bed and return to the chimney. If we did not do this, as there is another chimney near the middle of the back wall, and thus get pretty well enough of bottom heat for anything, and save our tank-making besides. 7. A small conical or saddle-back boiler will do all you want.

NAMES OF FRUIT (E. C. W.).—Your Pears are—1, *Autumn Colmar*; 2, *Bonne d'Étè*; 3, *St. Germain*. (*Mr. Price*).—Your Pear is the *Urbaniste*. (*G. Bethell*).—We believe your Grape is the *White Roman*. (*J. F. Lombard*).—1, This a remarkable-looking Apple and quite unknown to us—what is its history? 2, *Yorkshire Greening*; 3, *Hawthornden*; 4, *King of the Pippins*; 5, *Fondante d'Automne*. (*A. K.*)—No. 3, *Pear Doyenné Blanc*; 1, *Apple Hollandbury*; 2, unknown; 3, *Apple Dandelow's Seedling*. (*Mrs. S., an Old Subscriber*).—Your Pears are, 1, *White Doyenné*, 2, *Passe Colmar*; 3, *Louise Bonne* of Jersey; 4, not known; 5, *Red Doyenné*. Apples: 1, *Ribston Pippin*; 2, *Hughes' Golden Pippin*; 3, *Pearson's Plate*.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (*H. T. K.*)—Your plants are—1, *Polygonum lophanthoides*; 2, *Lotus corniculatus*; 3, *Epilobium montanum*; 4, *Atriplex patula*. (*W. Z.*)—1, the shrub with the red fruit is one of the *Spindle Trees*, *Ecnomys*, and we believe *atro-purpurea*, a native of North America; 2, is the *Honey Locust Tree*, *Gleditsia triacanthos*. (*A. B. C.*)—A *Tropæolum* certainly, but too much crushed for recognition; 2, *Cheilanthes rooseum*. (*J. E., Hagley*).—1, *Lastrea Filix-mas cristata*; 2, *Cheilanthes ternifolia*; 3, *O-munda regalis*; 4, *Polypodium vulgare*; 5, indeterminate; 6, *Pteris granifolia*. (*W. C. Wakefield*).—As far as we can make out a fasciated specimen of *Ionopodium aculea*, but it was much crushed before it reached us. (*A. B.*)—*Selaginella uncinata*, or *crista* as it is sometimes called. The colour is most likely affected by exposure. The Ferns are apparently *Cystopteris alpina*, and *C. bulbifera*, but not good specimens sent. They do not retain their fronds in winter. The others which you name are not deciduous. (*J. Ignorant*).—Your plant is the *Polygala myrtifolia* var. *grandiflora*. It roots readily from cuttings of the young shoots inserted in sand under a bell-glass.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

TO POULTRY EXHIBITORS.

WE view the Crystal Palace Show as one of the great events in the poultry world; and as "X. Y. Z." says that some few instructions will be as useful for Birmingham as for Sydenham, and as we are, moreover, assured by many contributors that they benefit by such, we will endeavour to supply the want.

Send the poultry in round baskets, and covered with canvass. Feed them before they start on sopped bread; let them eat as much as they will immediately before starting. Send them early that there may be no doubt of their being delivered in good time. We have seen many good birds delivered only "just too late" for competition, and others hurriedly thrust into a pen, and although very good, yet showing to a fatal disadvantage against birds that had been comfortably resting for hours.

Let your Spanish have clean faces. Choose birds in good feather. There must be no red face, nor must the cock have a falling or a twisted comb, nor should it be too large. The combs of the hens must fall. We would rather see a little, very little, fall at the back of the comb than any red on the face.

Choose your Dorkings large and square; the cock with good massive head and face, upright comb, straight breast, good straight legs, and well-formed five claws, the spur in its proper place, and not outside the leg. Let the hens or pullets match. Wash all their legs and feet clean, and wipe them dry. A falling comb is a disadvantage but not a disqualification. The same may be said of a crooked breast. A deficient claw is a positive disqualification. Game exhibitors have nothing to learn.

Your Cochins must have straight combs and yellow well-feathered legs. They should not be vulture-hocked, but we would rather see a slight vulture hock than a small twist in a comb. In the Grouse classes the cocks must have black breasts, and the less yellow there is about the hens the better.

Brahmas may be light or pencilled, pea or single-combed, but they must be all one or the other. The Light should be white, save a black-pencilled hackle, flight and tail. A shade of cream on the white is not objected to. The Pencilled should be pencilled all over. The cock should have straw hackle and saddle striped with black, black thighs, and black and white spotted breast. Pencilled hens with white breasts, and light ones with dark spotted backs are to be avoided. Mixture of comb is a disqualification.

In your Pencilled Hamburgs look for a straight, firm, well-piked and well-pointed comb. Nothing will compensate for a faulty comb; you must next look for a round, small, but perfectly white deaf ear, a pencilled body and tail, the pencilling distinct, not mossy or run into blotches of colour; the hackle as clear from spots as possible. If we are to speak comparatively, we should say we would show a bird with a faulty deaf-ear rather than one with a faulty comb. The cock's tail should be black, edged with gold or silver as it may be. Spangled Hamburgs should have striped hackles, and well-spangled bodies and breasts; wings well barred; perfectly white and round deaf-ears; full double comb, but very firm and straight. The Silver should have white tails tipped with black. The cocks of both breeds must have spangled breasts. Here for a choice of evils accept any one rather than a bad comb; that disqualifies.

The possession of a comb disqualifies Polish fowls; it is, therefore, the thing of all others to be avoided. In the Spangled breeds look for spangled breasts, laced and barred wings, topknots as free from white as possible.

Select your Game Bantams for close feathers and wings, small Game fowls, and not "pretty little Bantams" with saucy carriage and drooping wings. You want these latter qualities in your Sebrights. In the Black and White choose small birds with long tails. The Black should have white deaf-ears.

When your birds come home wash their faces and nostrils with some warm water, give to each a table-spoonful of castor oil, and feed them on sopped bread, or meal, or ground oats mixed with water, and slack enough to be almost fluid.

If your birds are beaten go and study the class in which they are shown, you will probably see why they were unsuccessful.

LONGRIDGE (PRESTON) AGRICULTURAL AND POULTRY SHOW.

THE first Show of this Society was held at Longridge on the 23rd ult.; and, notwithstanding the unfavourable weather, there was a very numerous attendance. The prizes, with one exception, were confined to old birds. There was a good entry and many really good birds were exhibited in the different classes; but some of them were deep in the moult and did not show to advantage. The following are the awards:—

DORKINGS.—First, J. Robinson, Garstang. Highly Commended, D. Parsons, Cuerden, Preston.

SPANISH.—First, T. Eastham. Highly Commended, T. Wareing.

GAME.—First, D. Parsons. Highly Commended, T. Eastham.

COCHIN-CHINA.—First, J. Robinson.

HAMBURGS (Golden-pencilled).—First, J. Robinson. (Silver-pencilled).

—First, E. Gardner. (Golden-spangled).—First, J. Robinson. (Silver-spangled).—First, J. Robinson.

BANTAMS (Any variety).—First, T. Eastham.

DUCKS (Aylesbury).—First, T. Philips. (Rouen).—First, T. Philips.

CHICKENS (Any variety).—First, D. Parsons (Spanish). Highly Commended, T. Pomfret, J. Chapman, and J. Robinson (White Dorkings).

The Judges were Messrs. H. P. Watson and James Tate, Preston; and Mr. Thomas Burnett, Hutton.

SUFFOLK POULTRY SHOW.

THE second grand annual poultry Exhibition was held in the Abbey grounds, Woodbridge, on the 24th and 25th of September, and the manner in which everything passed off must be a subject of great congratulation to the Committee; and the excellence of the arrangements made for the comfort of the visitors and safety of the birds, reflects the highest credit on the management.

In addition to money prizes, there was a silver cup for the best pen of Game fowls, which on a good competition was carried off by a very handsome pen of Black Reds, the property of Mr. Fletcher. This gentleman also exhibited some good pens of Duckwings, with which he was first in their class. The Spanish classes were weak both in numbers and quality. Amongst the Dorkings were some good birds, but the best pen unfortunately came in too late for competition. In the Cochins, Mr. Fowler's Buffs and Mr. Wright's Partridge well deserved their honours. Hamburgs were very badly represented, one prize only being awarded in the two classes. The "Variety class" of chickens was one of the best in the Show, Mr. Wright's Brahmas being, especially the cockerel, remarkably fine. The second prize was awarded to a pen of Silver Polands, also belonging to the same gentleman. The Game Cock Sweepstakes brought but two birds into competition, the prize going to a good pen from Mr. Dyas. The Bantams were not numerous, if we except the Game Bantam chickens.

Mr. Fowler was as usual invincible in Aylesbury Ducks, taking both prizes with beautiful pens. Rouens were well represented, being both large and good.

Mr. Fowler was first in Geese with a remarkably fine pen, such, indeed, as Aylesbury alone can produce.

There were a few dogs exhibited, but no prizes were offered in this department. Before closing our remarks we must again congratulate the Committee on their success and wish them a continuance of it, and that in future years we may have to announce, as we have now, that their accounts for the season have been closed with a good balance in hand.

SPANISH.—First and Third, J. Wright, Woodbridge. Second, Mrs. G. Craigie, Woodlands, Essex. CHICKENS.—First, Mrs. Pattison, Maldon. Second, W. Stubbs, Woodbridge.

DORKINGS (Coloured or White).—Cup, H. Lingwood, Needham Market. Second, J. Frost, Parham (Coloured). Third, J. K. Fowler, Aylesbury. CHICKENS.—First, R. P. Revett, Parham. Second, J. Smith, Parham (Coloured). Highly Commended, J. Frost (Coloured).

COCHIN-CHINA (Coloured or White).—Prize, J. B. Walthew, Ormskirk (Partridge). CHICKENS.—First, J. K. Fowler, Aylesbury (Buff Cochins). Second, J. Wright, Woodbridge. Highly Commended, Rev. G. Gilbert, Claxton (Buff). Commended, Rev. H. Curry, Needham Market (Partridge).

GAME (Black-breasted and other Reds).—First, A. B. Dyas, Madeley. Second, S. Matthews, Stowmarket. Third, J. R. Kersey, Winston (Brown Reds). CHICKENS.—First, J. Fletcher, Manchester (Black Reds). Second, A. B. Dyas. Highly Commended, S. Matthews (Black Reds). Commended, S. Matthews.

GAME (Duckwings and other Greys and Blues).—Prize, J. Goodwin, Hollisley (Duckwings). *Chickens*.—First, J. Fletcher, Manchester (Duckwings). Second, S. Matthews, Stowmarket. Highly Commended, A. B. Dyas, Madeley. Commended, G. Barrell (Piles).

HAMBUROHS (Golden-spangled).—Second, C. Wood, Woodbridge. First prize withheld.

HAMBUROHS (Silver-spangled).—*Chickens*.—Prize, J. Cullingford.

ANY VARIETY NOT COMPRISED IN THE BEFORE-MENTIONED CLASSES.—First, J. Wright, Woodbridge (Brahma Pootra). Second, S. Waters, Woodbridge Road, Ipswich (Crève Cœur). *Chickens*.—First and Second, J. Wright (Brahma Pootra and Silver Poland). Highly Commended, C. Wood, Woodbridge (Gold Poland); J. K. Fowler, Aylesbury (Brahma Pootra); S. Waters. Commended, F. Whistock, Woodbridge (Brahma Pootra).

GAME COCK.—Prize, A. B. Dyas, Madeley. Commended, J. Goodwin, Hollisley (Black Red).

GAME BANTAMS.—First and Second, W. Dowling, Woodbridge (Black-breasted Reds). *Chickens*.—First, J. K. Fowler, Aylesbury. Second, F. Wigg, Woodbridge (Black-breasted).

BANTAMS (Any variety).—First, C. Wood, Woodbridge. *Chickens*.—First and Second, T. Newson, Tunstall.

DECKS (White Aylesbury).—First and Second, J. K. Fowler, Aylesbury. Highly Commended, J. H. Read, Hasketon; Mrs. Pattison, Maldon.

DECKS (Rouen).—First, N. G. Barthropp, Hacheston. Second, J. Cooke, Colchester. Commended, J. E. Kersey, Winston; J. K. Fowler, Aylesbury.

GESE.—First, J. K. Fowler, Aylesbury (Toulouse). Second, T. Cracknell, Framlingham. Highly Commended, T. Cracknell.

TURKEYS.—First and Second, T. Cracknell (White and Black).

The Judge was Mr. Geo. Saunders Sainsbury, of Devizes.

ABERGAVENNY AGRICULTURAL AND POULTRY SHOW.

The following prizes were awarded in the poultry department of the above Show.

GAME.—Prize, G. Pritchard, Llanvihangel. *Chickens*.—Prize, G. Pritchard. HAMBURGH (Gold-spangled).—Prize, J. Pye, Abergavenny. *Chickens*.—Prize, J. Pye.

HAMBURGH (Silver-pencilled).—Prize, D. Davies, Clydach.

DORKINGS.—Prize, W. Saunders, Abergavenny. Commended, R. Rees. *Chickens*.—Prize, J. Logan. Highly Commended, Rev. W. Corfield. Commended, W. Saunders, Abergavenny.

SPANISH.—Prize, Mrs. Lewis, Crickhowell. *Chickens*.—Prize, Mrs. Lewis. BANTAMS.—Prize, D. Jenkins, Llanvihangel.

GESE.—Prize, R. Rees, Abergavenny. Commended, P. Morgan. *Goslings*.—Prize, R. Rees. (Class Highly Commended.)

DECKS (Aylesbury).—Prize, J. Logan. Highly Commended, J. Pye, Abergavenny. Commended, R. Rees, Abergavenny. *Ducklings*.—Prize, J. Logan. Highly Commended, G. Pritchard; J. Pye.

TURKEYS.—Prize, Mrs. Holford, Buckland. *Poultis*.—Prize, Mrs. Holford.

The Judge was Mr. Rowland Henry Nicholas, Malpas, near Newport.

WOODSTOCK AGRICULTURAL SOCIETY'S POULTRY SHOW.

The following prizes were awarded at this Exhibition on the 29th ultimo:—

SPANISH.—Prize, Rev. J. Dodd, Hampton Poyle. *Chickens*.—Prize, Rev. J. Dodd.

DORKING (Coloured).—Prize, Sir H. W. Dashwood. *Chickens*.—Prize, Sir H. W. Dashwood.

BRAMAS.—Prize, the Duchess of Marlborough.

COCHIN-CHINA.—Prize, Colonel North, M.P. *Chickens*.—Prize, Rev. J. Dodd.

HAMBURGH (Spangled).—Prize, F. Hillersden, Kirtlington. Highly Commended.—Shuffrey. *Chickens*.—Prize, F. Hillersden.

HAMBURGH (Pencilled).—Prize, J. James, Woodstock. Commended, — Innes. *Chickens*.—Prize, J. James.

GAME.—Prize, Goma, Shipton.

DECKS (Coloured).—Prize, Colonel North, M.P. Wroxton. Highly Commended.—Innes; — Pratt. *Ducklings*.—Prize, Hon. Miss Dillon.

Highly Commended, T. Smith.

DECKS (Aylesbury).—Prize, — Pratt, Woodstock. Commended, Rev. J. Dodd; Col. Bowyer.

GESE (White).—Prize, Hon. Miss Dillon. *Goslings*.—Prize, Hon. Miss Dillon.

GESE (Grey).—Prize, Col. North, M.P. *Goslings*.—Prize, The Duchess of Marlborough.

TURKEYS (Black).—Prize, H. L. Gaskell. *Poultis*.—Prize, H. L. Gaskell.

TURKEYS (Grey).—Prize, Col. Bowyer.

CHAMPION PRIZES FOR GREY GESE.—Prize, Col. North, M.P. *Goslings*.—Prize, The Duchess of Marlborough.

Mr. G. Botham, of Wexham Court, was Judge.

BROUGHTON AND GOOSNARGH (PRESTON) AGRICULTURAL AND POULTRY SHOW.

This poultry Show was held at Broughton on the 23rd ult. The following are the awards:—

DORKINGS (White, Grey, or Speckled).—First, J. Robinson, Garstang. *Chickens*.—First, J. Robinson.

SPANISH.—First, J. Robinson. *Chickens*.—First, J. Robinson.

GAME.—First, J. Robinson. *Chickens*.—First, T. Wareing.

GAME COCK.—First, C. R. Jackson, Preston.

COCHIN-CHINA.—First, J. Robinson. *Chickens*.—First, J. Robinson.

HAMBURGH (Golden-pencilled, Silver-pencilled, Golden-spangled, Silver-spangled).—Prize, J. Robinson. *Chickens*.—(Golden-pencilled, Silver-pencilled, Golden-spangled, Silver-spangled).—Prize, J. Robinson.

BANTAMS.—First, P. Catterall, jun. *Hen*.—First, P. Catterall, jun.

BRAMA POOTRA.—First, — Wilson. *Chickens*.—First, C. R. Jackson.

DECKS (Aylesbury).—First, J. Robinson. *Ducklings*.—First, J. Rigby.

(Rouen).—First, J. Robinson.

GAME CHICKENS.—First, J. Harrison, jun.

PIGEONS.—First, J. Stones, Preston. Extra prize, T. Wareing.

The Judges were Messrs. Higson and Blackburn, Preston.

BIRMINGHAM POULTRY SHOW.

A FEW changes have been made in the poultry prize list, the most important of which is the withdrawal of the classes for Silver Grey Dorkings. The Council, some years ago, at the request of several exhibitors gave separate classes to the Greys, but the result has been by no means satisfactory, the entries not being equal to what was anticipated; and instead of any improvement being witnessed from year to year in the size and quality of the birds shown, there has been a marked deterioration. It became obvious, therefore, that it was a mistake to encourage attempts at breeding Dorkings of a particular feather, and, consequently, the change we have mentioned was determined upon. At the same time the prizes for coloured Dorkings have very properly been increased, there now being five in the class for old birds, and the same number in that for chickens—£5, £4, £3, £2, and £1, three for hens and pullets—£3, £2, and £1, and four for single Dorking cocks—£5, £3, £2, and £1. Separate classes are now given to Crève Cœur and Black Hamburg fowls, the excellent specimens of the two varieties shown last year having well won for them this distinction. The special premiums in the poultry department this year are as follows:—By a few amateurs, two silver cups, value seven guineas each, for the best pens of Cinnamon or Buff Cochins in classes 11 and 12; by Mr. G. F. Greensill, a cup, value five guineas, for the best pen of Game fowl in the Exhibition; and by Mr. M. Billing, a cup of the like value for the best Game cock competing in the three classes for single birds—72, 73, and 74.

The prize list for Pigeons has been re-arranged, and single birds will now be exhibited in some of the classes, the colours being also separated—changes which will, we have no doubt, be generally acceptable to those who lend their co-operation in making up a very interesting and beautiful division of the Show.

The entries this year will close on Saturday, the 31st inst., and those of our readers who require certificates and any information regarding the arrangements should at once apply to Mr. Lythall, the Secretary.—(*Midland Counties Herald*.)

CROWING A NUISANCE.

At the Weston-super-Mare Police-office the following rather remarkable petition was recently laid before the Bench:—

"To the Magistrates of Weston-super-Mare.—The following petition for the abatement of a nuisance is respectfully addressed by the inhabitants of Sydenham Terrace, Shouldham Street, &c.

"Gentlemen.—Whereas since the middle of July the above-mentioned neighbourhood has been disturbed nightly by the crowing of a remarkably fine Spanish cock, from twelve o'clock at night until late in the morning, so as to banish sleep from the inhabitants of the back rooms in the houses mentioned above; your petitioners pray that Mr. Williams, the shoemaker (to whom the cock belongs) may be compelled either to keep the cock where it cannot be heard beyond his own premises until a reasonable hour in the morning, or to part with it. This petition has been delayed for the purpose of trying remonstrances with the proprietor of the cock, but they have been disregarded, and treated with ridicule and contempt. Invalids suffer so much from want of rest that they will be compelled to remove, and even healthy persons will not remain where their rest is incessantly broken, so that your petitioners will be much injured if the nuisance is

not speedily abated. They therefore pray your Worships' powerful decision upon the subject."

Mr. Kinglake, after reading the petition, said it was rather a difficult subject on which to give advice. He supposed that the rights and privileges of the lord of the poultry-yard had been interfered with, and his domestic happiness blighted, or he would not have crowded out of his grief at so early a period (laughter). It might seem to the Court a laughing matter, but in truth the loud crowing of a cock in the ears of an invalid was as great a nuisance as the howling of a dog at night. He remembered the judgment of the County Court Judge at Exeter, where the owner of a Bantam cock was made to pay the expenses of a neighbour changing his lodgings, as the cock had been known to have crowed 500 times in less than five hours. The judgment was appealed against, but the Superior Court confirmed the County Court Judge's opinion, and laid down a wise and humane principle that no one had a right to injure the health or peace of his neighbour. Mr. Williams was a respectable tradesman, and would, no doubt, confine the cock in a box, where his crowing could not be heard.

APIARIAN NOTES.

(Continued from page 282.)

MY APIARY.—To sum up the proceeds of my bees this season I give the following table, some little modification in the results having occurred. I have found since writing the paper which appeared on the 22nd of September, that the super taken from No. 7 weighed 30 lbs. instead of 35 lbs., the mistake having arisen from miscalculating the tare of the box. In one or two cases an increase is to be noted.

No. of hive.	Remarks.	Honey taken.	No. of hive.	Remarks.	Honey taken.
1	Artificial swarm, 1863	0 lbs	14	Ligurian	50 lbs
2	Old stock	0	15	Artificial stock	0
3	Artificial swarm, 1862	12	17	Sent off two swarms	15
4	Five-year-old stock	20	19	Deprived of bees & brood	0
5	Three off the swarm	0	20	Large swarm lost	15
6	Gave an immense swarm	10	21	Eighteen-frame hive	35
7	Old stock	30	22	Suspended hive	10
8	Gave swarm and	8	23	Artificial swarm made	8
9	Old stock broken up	48	24	Broken up	0
10	Ligurian	54	25	Artificial swarm	0
11	New swarm	0			
12	New swarm	6	Total		331

Having in the spring united two stocks to others and given away a third, there remain sixteen available stocks from which the harvest has been obtained: the residue being composed of natural and artificial swarms, or stocks lately fabricated with driven bees supplied with frames of comb removed from my strongest colonies. This will show an average of 20 lbs. 11 ozs. of honey afforded by each hive, together with swarms from some of them: certainly not a bad average considering the circumstances under which I am compelled to follow the pursuit of my favourite hobby. I could very well have taken 100 lbs. more from these stocks, the hives being very large and generally more than sufficiently stored with honey. The readiness with which the frames can be removed renders this an easy and a safe operation, as the exact condition of the hive can be so readily ascertained.

Three only of the whole number have done very well, the remainder but moderately so. This may in great part be attributed to my having taxed the powers of the majority of my hives to a very great extent last season in rearing Ligurian queens, and in making artificial swarms. In consequence of this, combined with the miserable summer we had in 1862, necessitating an extraordinary amount of feeding, my hives were not as a rule in a position to make the most of a good honey-harvest, with the exception of Nos. 10, 14, and 21, which acquitted themselves very well; and of Nos. 6, 17, and 20, which would swarm rather than work in their supers.

THE REV. K. KIRWAN'S APIARY has, I believe, proved tolerably prosperous. From one of three artificial swarms made last year from his original Ligurian stock he obtained a very beautiful box of honey of 42 lbs. weight. The super was a large mahogany-framed glass box capable of holding twelve bars of a Woodbury-hive. A less number was in reality used, so that some of the combs attained a consider-

able thickness. I also observed a very nice bell-glass, but do not remember the weight of its contents.

MR. GEORGE FOX'S APIARY.—The most astonishing results of scientific bee-keeping have been manifested in the apiary of this gentleman, who resides at Kingsbridge, in this county of Devon.

1st. From a cottager's common straw hive, an old stock, he took off a glass box super, the nett contents of which were 109½ lbs. This super was worked on the plan of his adjusting principle, the combs being raised gradually within the glass. The combs are about 19 inches in depth, and some of them would weigh about 20 lbs. each.

2nd. From a box-hive, which was entirely colonised by two lots of driven bees last autumn, he obtained a glass box super of 112 lbs. nett contents. This also was on the adjusting principle, only in this instance the glass box fitted down outside the stock-box, and was itself gradually raised as the bees constructed combs.

3rd. An octagonal glass stock-box peopled by a swarm in the first week in June of this summer, from which the bees were driven out and united to another stock, holds the hardly less astonishing quantity of 82 lbs. 14 ozs. of pure honeycomb.

The honey in all three boxes is of the most beautiful quality and delicate colour, and I should doubt if supers at all approaching to these in weight and quality have ever been seen in this country. I have been informed that the owner was offered for the lot of three boxes the large sum of £40, which he declined, preferring to retain possession of them as wonderful specimens of the industry of the bees.

The produce of his apiary may be summed up as follows:—

No. of hive.	Remarks.	Honey. lbs. oz.
6	A driven swarm	10 6
7	Glass box super	109 8
8	Octagon stock-box, a swarm of this summer	82 14
10	Glass box super	112 0
11	Three glasses	20 0
12	Driven bees, a super	15 0
Total		349 12

Thus it appears that 350 lbs. have been deprived, without injury to the bees, from six stocks in one garden, an average of 58 lbs. each.

The remainder of his hives, No. 1, 2, 3, 4, 5, and 9, are principally either swarms, or stocks from which swarms have issued, and no honey has been taken. With one exception, a Ligurian colony, they are in good condition for next year.

Certainly, I did rather plume myself upon my supers of 54 lbs. and 50 lbs. weight respectively, but now is my pride laid low. What are they to those in the possession of this truly practical and scientific bee-keeper? Nor must it be at all left open to any doubt as to the correctness of the weights stated. They are in each case the exact weight of the contents exclusive of the boxes. The total gross weight of one super is 126 lbs., and of the others 123½ lbs. As this successful apiarist would not accept of any assistance in their removal, it is not difficult to imagine by those who have lifted off heavy supers, the great labour it must have been to him. In fact, his expression in a letter to me announcing the occurrence, was, that he was stiff, sore, and weary, with the amount of exertion necessary in removing these ponderous supers from the hives into the house.

I have had in my possession for the last twelve years a beautifully-filled glass globe which also came from the apiary of the same gentleman. This was worked in 1857, on the top of a common straw hive, and I have long fondly imagined it to have been most probably the largest and handsomest glass of honey in the kingdom. Its nett weight was 48 lbs. 6 ozs. It still stands as an ornament in my drawing-room, but I must confess to its now being of less value in my eyes than before these much larger glass supers were heard of.

But there is another confession to be made. These are all the produce of our common English black bees, and our bee-master is rather inclined to crow accordingly over myself and others who have been sticklers in favour of the Ligurians. It is, perhaps, an accidental circumstance, but the hives which have afforded me the largest and best supplies of honey, have this year been Ligurians, none of those of the black bee having nearly approached to them in this

respect. Also, if I am not much mistaken, Mr. Kirwan informed me that his black bees had done nothing as compared to his stocks of Ligurian blood.

Notwithstanding that I am fully convinced of the superiority of Ligurians with regard to the extraordinary breeding powers of the queen, and that the bees are apparently far more actively engaged in prosecuting their out-door labours; and notwithstanding my admiration of the beauty of both queens and workers, in which they greatly excel the common queen and bees, yet I am by no means satisfied that they possess any superiority over the common bees as honey-gatherers. The excessive fecundity of the queens and the extraordinary manner in which the combs are filled with eggs by them, must be an enormous tax on the labours of the foragers. There is also, I think, a much greater disposition to throw off swarms, which militates against the filling of supers. On the whole, therefore, I am inclined to think that the common bees carry off the palm in honey-gathering; but do not consider that we have as yet had sufficient experience to warrant us in coming to any definite conclusion on this point.

In Kingsbridge and its neighbourhood swarms have prevailed to a great extent, the majority of which have, I hear, done very well. Mr. G. Fox lately took a walk into the country to ascertain the truth of a report, that a person has had eleven swarms from two stocks, and found the state of the case to be actually thus:—

Two old hives, A and B—A threw off three swarms, B threw off two swarms. First swarm from A threw off two swarms, first swarm from B threw off three swarms. A second swarm from one of the first swarms also sent off a swarm. All the swarms were sold except one. One of the two old stocks was burnt, and yielded 50 lbs. of honey. In truth this has been a remarkable season for bees, both as respects honey-gathering and swarming. I fear it may be many years before we experience its equal.—S. BEVAN FOX, *Exeter*.

VIRGIN QUEENS—PARTHENOGENESIS.

THE first case referred to by Mr. Shearer in page 283 is a very remarkable one. I gather from the dates given that the queen commenced egg-laying at the usual time of a fecundated queen—viz., when she was from fifteen to seventeen days old. As I learn from a private letter that she still lays the eggs of drones only, she may now, of course, be looked upon as a confirmed drone-breeder. This case completely negatives Huber's hypothesis of retarded impregnation; and if Mr. Shearer has no use for her I should be much obliged by his sending me the queen alive in a small box by post, in order that I may ascertain beyond doubt, by means of the microscope, whether or not she remains a virgin.

The second is an instance of fertile workers, several of which have already come under my observation, but in which I never could distinguish fertile from ordinary workers.

I look upon parthenogenesis in the honey bee as one of those grand discoveries in the light of which many perplexities become clear, and many apparent contradictions are reconciled. As I have before stated, it has been established by evidence of the most incontrovertible character, on the strength of which it is now received as an unquestionable fact by all our most distinguished naturalists as well as by—A DEVONSHIRE BEE-KEEPER.

SUCCESSFUL INTRODUCTION OF A LIGURIAN QUEEN.

HAVING had a Ligurian queen sent to me by Mr. Woodbury to put into a hive of common bees, which I had deprived of their own queen on the 9th of September, on the 14th I destroyed seven queen cells which they were rearing; four were sealed up, the others had a grub in each.

The queen having arrived from Exeter on the 16th, too late in the evening to have done anything with her, on the following day I found her rather weak and some of the bees dead. After giving her some honey, which she devoured greedily, she soon revived and took to flying, when I should have lost her had I not been in a vinery.

Being aware of the danger of introducing a strange queen into a hive, I took out a bar-frame with a few bees on the

comb, and then introduced her to her new subjects; but they seized her at once and would have killed her had I not taken her away.

I then formed a cylinder of perforated zinc 1 inch in diameter and 3 inches long, with a cork in each end, put in a small piece of honeycomb in case her rebellious subjects would not feed her while in the cage, and suspended her in the centre of the hive till the following day, when again bringing her into close contact with the bees, still some of them would have killed her, although not so much inclined to do so as before. I examined the combs to see if the bees were rearing any more queens, and found two of a good size which I destroyed, and I again suspended her till the following day, when I introduced her to the bees. They took to her with apparent delight, and in ten days after leaving Exeter she was laying eggs; so that with a little comb I see no difficulty in introducing Ligurian queens into stocks of common bees.

When they rejected her on the second trial, having kept their own queen in a box in case of accident, I introduced her to them, and they knew her at once although she had been parted from them ten days.

I always understood that if the eggs were more than three days old they would not form a queen. In this case they attempted it from eggs ten days old.—ALEX. SHEARER.

[The risk is much diminished when the original queen can be removed some days beforehand; but even with this precaution it is very probable that the operation might have terminated fatally but for the apiarian skill displayed by Mr. Shearer.]

HONEYDEW.

I WAS astonished to observe that some of your apiarian readers doubted the fact of bees working on honeydew.

In this part of the country every one knows that when there is honeydew the bees do well. This year it was plentiful on the oak, the beech, and lime, and on these trees I saw them alight in great numbers, suck up the drop of honey on the edge of the leaf, and then fly away. Those mornings in which there was plenty of dew the bees were at work an hour or two earlier.

The honeydew is only on certain individual trees of the kinds mentioned: some have it less or more every year. If a slight shower or a dewy night happens then it is in abundance.—ALEX. SHEARER.

TWO QUEENS IN ONE HIVE—FOUL BROOD.

IN reply to a query from an esteemed correspondent, I may state that the supernumerary queen whose presence under such peculiar circumstances so much puzzled me, was unquestionably reared in the hive. This fact became apparent upon a subsequent examination, which disclosed a naturally-opened and otherwise perfectly-formed royal cell at the bottom of one of the combs.

Having, therefore, afforded every information in my power regarding the ephemeral existence and premature death of the sovereign, which when first discovered occupied so anomalous a position, I would remark, that although Mr. Lowe's article, in page 283, affords indubitable proofs of accurate observation and great apiarian skill, I do not think he has succeeded in solving the problem submitted to him. Whilst venturing to hint that my experience in such matters may possibly be equal to his own, I may add that although it unquestionably confirms the correctness of his general conclusions, it fails to throw light on the queries which I again take leave to submit—"What under the circumstances can have caused the bees to raise a second queen? and what can have induced the queen regnant to brook so near a rival to the throne?" As before, "I pause for a reply."

With regard to foul brood, it appears to me that Mr. Lowe, finding the weight of evidence so entirely against him, may not be unwilling to withdraw from the discussion; but after saying, "If it is to be termed a disease at all, let it be described as an entirely artificial one," I cannot understand his declaring "A STEWARTON APIARIAN" to be "quite at sea" in supposing that he treated the subject on these principles.

In conclusion I take leave to correct Mr. Lowe's misstatement with regard to my calling Ayrshire "the great centre of bee knowledge." The phrase, as I stated at the time, was not my own, but that of "A RENFREWSHIRE BEE-KEEPER." Entertaining as I do a very great respect for the opinions of this gentleman, and having arrived at a high estimate of the practical knowledge of bee-culture which obtains in the locality referred to, I may yet be permitted to doubt whether "the great centre of bee knowledge" is to be found anywhere within the limits of the United Kingdom.—A DEVONSHIRE BEE-KEEPER.

UNITING SWARMS.

I HAD on the 2nd or 3rd of last June three fine swarms thrown off, for which I was not prepared; and as it was impossible to procure in our sleepy neighbourhood any but the common straw hives, I was obliged to use them, and I have now three hives very full and heavy, which I do not wish to retain: can I unite the three or even two of them without killing the bees?—A SUBSCRIBER SINCE 1856.

[If you can succeed in driving and uniting bees as described in page 59 of the new edition of "Bee-keeping for the Many" you will find little difficulty in transferring the inhabitants of your three common hives to an unfurnished habitation. They should then be fed by means of an inverted bottle with its mouth covered with cap-net, and containing at least a pint of food, which must be refilled every evening until the nett contents of the hive reach 15 lbs. This is an interesting experiment, and one that is likely to result in forming a strong stock next spring; but if it involves too much trouble the expelled bees may advantageously be united to your other stocks in the manner directed in the valuable little Manual above referred to.—A DEVONSHIRE BEE-KEEPER.]

DRIVING BEES.

It is quite a custom in this part of the country to drive bees; it is termed here "whipping them," and is generally performed just before they are taken to the heather.

Two or three puffs are given to the hive from a piece of burning rag, and then it is turned mouth uppermost. An empty hive is put on the top, and it is then gently struck with a piece of stick all round the sides. In a few minutes the bees all ascend into the empty hive, and are then taken to the heather, when, if a good season, they will make from 20 lbs., 30 lbs., or 40 lbs. of honey and comb, and if a bad season of course they die. Still, in many cases, the practice is attended with good results. There is no difficulty in performing the operation here; I myself did it to four hives the other day, and it did not take more than ten minutes for each.—ALEX. SHEARER.

[What becomes of the unhatched brood when bees are driven into an empty hive prior to their autumnal removal to the heather? We believe our Scottish friends are too well aware of its value to allow it to perish; but Mr. Shearer has omitted to describe the means by which it is preserved.]

THE HONEY SEASON IN EDINBURGH.

This has been a most singular season here. Some bee-keepers have nothing but disasters and empty hives as reminiscences of it; others in the same neighbourhood, and in many cases with part of their stock only, have obtained such extraordinary results in the shape of virgin swarms and supers that I will not venture to mention them, so incredible are they.

Nearly all my hives have been receiving the benefits of the heath blossom among the Pentland Hills, ten miles distant, since the beginning of August. I received them back on Saturday evening much heavier, but with the supers only half filled; some of them not so much, even in cases where the stock is above 40 lbs.

I have observed that in the early part of the season my bees work very readily in a super if there are plenty of bees in the hive; but in autumn they fill the hive first in preference to the super.—J. B.

PROTECTION OF IRON FROM RUST.

IN course of a recent discussion on various subjects at the Society of Arts, in a Committee of Reference on Mechanics and Engineering, Mr. C. F. Varley said—All attempts to use galvanised iron for roofs in large towns failed, from the smoke attacking the galvanised metal; and tinned iron did not resist the action of smoke so well even as zinc. All the experiments he had seen of coppering iron had failed, unless it was done in so expensive a manner as not to be practicable for any extended use of it. What they required was a covering of lead, or lead and antimony, put upon the iron so as to combine the stiffness and cheapness of iron with the durability of lead. Owing to the multiplicity of telegraph wires in the metropolis, danger might result from the falling of long spans of wire, through their being rusted away. Colonel Chaffner said the coverings of houses in some countries were of tinned iron. In America this was largely used instead of lead. In St. Petersburg and Moscow iron was mostly used, but it required frequent painting. In the telegraph service he had tried many expedients for the preservation of the wires by galvanising, and the use of linseed and other oils. He had boiled the wires in linseed oil with beneficial results; but they would decay. Mr. Varley, sen., said if iron was heated and passed through oil, the pores were filled up, and the metal lasted a long time. Mr. Reveley mentioned that iron heated and covered with asphaltum or mineral bitumen in the solid state had resisted a moist atmosphere for fifteen years. He had found the natural asphaltum the best, and he had not succeeded so well with liquid asphalt. With all other materials he had found the rust penetrated underneath. Mr. John Braithwaite said the mode of arresting it adopted by his father, and which he had himself followed for the last fifty years, was by painting the iron with red lead. Painting with white lead was of no use, as the acid used in the preparation of it produced swelling effects. He had inspected a well where he had fixed an engine forty-five years ago. The rods which had been placed in this well, 200 feet deep, were painted with pure red lead; and on taking them up, he found that their weight was precisely the same as when they were put down forty-five years ago.

OUR LETTER BOX.

TOTLOUSE GEESSE (*G. Hassel*).—Write to Capt. Hornby, Knowsley Cottage, Ipswich.

CORNS IN GEESSE (*H. C. S.*).—Old Geesse are subject to corns, especially where they have little water. Callusities on the feet are often caused where Geesse are kept in confinement, and the flooring of their house is stone or brick. Nothing does the feet more good than to walk on wet grass. It removes the corn-like substance you mention.

TOWLS TROUBLED WITH CORNS (*Lee*).—The best remedy we have found for this is cutting the affected part away as much as possible, and then rubbing it over with caustic. Some corns are, however, more like abscesses: tie a plaster of linseed meal over the wound for a day or two after cutting, and confine the bird to a dry place, after which apply the caustic, and in a week or two a cure is effected. It, however, sometimes happens that these humours must have vent somewhere, and we cannot affirm that the remedies above will succeed in all cases, although in general they will do so. You will see some full notes on Walnut-tree culture in our next Number.

HIVES WITH CORNS, BUT NO HONEY (*A. Nether*).—As so few particulars are given, we can only guess at the causes of the bees decamping from the six hives. The probability is that the defunct colonies are old stocks which have swarmed this year, and have either failed to raise young queens or have had the misfortune to lose these indispensable members of the bee community during their wedding flights. The defective appearance of strength only a week or two since was due to crowds of robbers plundering the hives' stores. The only mode of preventing these mishaps is to adopt hives with moveable combs and ascertain, by actual examination of the interior, the existence of a sovereign in each community before her loss becomes irreparable.

JAVA SPARROWS' FEATHERS CHANGING COLOUR (*Ferriera*).—It is not an uncommon occurrence for the cheek feathers of the Java Sparrow to change colour from white to black when the birds moult. Probably they may again become white the next moult.

LONDON MARKETS.—OCTOBER 12.

POULTRY.

There is still a very large supply of poultry and a sorry trade. Pheasants are plentiful, Geese are scarce, and Partridges hardly an average supply.

26	M	Whitethorn leaves fall.	55.3	36.6	45.9	14	44	6	44	4	17	15	209

From observations taken near London during the last thirty-six years, the average day temperature of the week is 57.4°, and its night temperature 39.8°. The greatest heat was 73°, on the 21st, 1831; and the lowest cold, 17°, on the 23rd, 1859. The greatest fall of rain was 0.96 inch.

HOW TO GROW STRAWBERRIES SUCCESSFULLY.

HOUGH I take up my pen with the intention of writing a brief article on the above subject, it is not in the hope of communicating anything new, nor yet of presenting an old subject in a new dress; but having been successful in producing fine fruit and heavy crops, I think my mode of practice may be interesting to some of the readers of *THE JOURNAL OF HORTICULTURE*. In order to grow superior Strawberries it is necessary to lay a good foundation, or the after-management will prove a failure. The first point which I consider demands attention is the preparation of the soil. This should be done in the winter. Many Strawberry-growers put off this important operation until July or August, when they are about to form their new plantations, which I consider a mistake. I prefer selecting the piece of ground on which it is intended to grow Strawberries in the early part of the winter. When the weather is tolerably dry, or, what is better still, rather frosty, it should be trenched to the depth of from 24 to 30 inches. The Strawberry delights in a deep, loamy, or rather adhesive soil, and where light and sandy it may be trenched to the depth of 3 feet with advantage.

I need not enter into details respecting the operation of trenching. Suffice it to say that, during the operation, dung should be supplied with an unsparing hand. I invariably place plenty of coarse manure at the bottom of the trench and part of the way up, and some which is more decomposed nearer the surface: the coarse manure becomes decayed before the roots get down to it.

Having finished the trenching and left the surface rough, it may lie fallow and exposed to the fertilising influences of frost and snow until the following spring. It may then be planted with a crop of early Potatoes or early Cauliflowers, which can be cleared away before the ground is wanted for the Strawberries.

The Potatoes or Cauliflowers being all removed, the ground must receive another surface-dressing of good rotten stable-dung and be carefully dug over, well incorporating the dung in the upper portion of the soil during the digging.

The ground being ready, next comes under consideration the propagation of the plants. Care should be taken in the selection of runners, those only being employed that are stout and healthy, with a round plump bud in the centre, and they must be from vigorous-fruited plants. This is better than taking plants at random, for I believe that barren plants produce a barren progeny.

The runners must be layered in large 48-pots, well drained, and filled with a rich loamy soil mixed with

rotten dung, and they must not be allowed to suffer for want of water. They will make rapid progress in this rich compost; and as soon as they are fairly rooted they may be severed from the parent plants and placed in a shady situation until the pots are tolerably full of roots, when they must be planted immediately. My practice is to plant them in beds, two rows in a bed, with an alley between each bed. The beds are made 3½ feet wide, and the alleys 2½ feet. Each plant is placed 3 feet apart in the rows in half-quincunx order—thus . . . and the rows on the bed are 2½ feet asunder. This leaves the rows at each side of the bed 3½ feet from each other. By so planting a little more space is left between each bed to walk on without treading on the fruit. But whether the ground is formed into beds or not, which is simply a matter of choice, the plants must have plenty of space. If they are in rows, the ground not being formed into beds, each row must be 3 feet apart, and the plants at the least 3 feet asunder in the rows. Strawberries highly cultivated want plenty of room to develop themselves, and they will well repay the cultivator for his liberal treatment. They must be freely supplied with water during dry weather to encourage a free and vigorous growth. The plants must also be kept free from runners, and the ground clear of weeds.

Now, if attention has been paid to every particular, we may look for a very respectable crop of fruit in the following year. The crop will be the heaviest the second year, but we have the largest berries the first season.

The British Queen produced with us this last summer fruit averaging about twenty to the pound. We had single berries weighing about 1 oz. each, and which were from 5 to 7 inches in circumference. One very important point I noticed last summer in the propagation of the plants: those runners placed in the largest pots made by far the largest plants, and bore double the quantity of fruit that those placed in small pots did. Hence I recommend the runners to be placed in large 48-pots filled with rich compost, in preference to layering them in pots of smaller dimensions.

I will now advert to the management of Strawberries during their growing and resting season. Early in the spring they must receive a thorough good cleaning; every dead and decaying leaf must be removed, every runner carefully cut away, and the ground well hoed and cleared of all weeds. This operation must not only be attended to once, but as the runners appear they must be cut off unless required for propagation. It has been a question with some people whether runners do not support the parent plant. This I consider is a mistake. There can be no doubt that every runner abstracts until it has become rooted much support from its parent; and the production of runners, like that of seeds of any kind, is an effort of nature to reproduce its own species.

As soon as the plants are in bloom some protecting material should be placed beneath the trusses of bloom to prevent the fruit from being injured by heavy rain. Some gardeners use clean straw, others apply litter from

the stable; and some who cannot procure either of the above use grass mowings from the pleasure grounds, but where it can be obtained stubble from a corn field is to be preferred.

The plants should never suffer from want of water from the time the first bloom expands until the last fruit is gathered.

Many gardeners, as soon as the fruit was gathered, used to cut or mow off all the leaves; but this barbarous practice has happily passed away. But the question arises, What is to be done with the foliage? No doubt by the end of October it has performed the functions of keeping the plant in health and vigour, but it has other work to do. The plant or crowns require protection in winter, and what is more suitable than their own foliage? Therefore it is injudicious to remove the leaves in the autumn, and they should remain till spring.

There is one other question which remains to be discussed—Is it right to dig between the plants? My practice is to dig deep and manure heavily previous to planting. I then surface-dress the beds in the autumn, and fork the middle of the alleys a few inches deep, turning in a quantity of manure at the same time. The manure on the beds acts as a protection to the surface-roots, and forking the alleys loosens the soil made sad by being frequently walked upon. Where they are planted in rows, not in beds, the middle of the row may be forked down one fork wide with advantage.

The foregoing is the substance of my practice, and I can say it has been successful: indeed I have thought it satisfactory when I have seen the admiration of my employers, and basket after basket full of fine, large, luscious fruit has been gathered.

With regard to sorts I can say but little. I do not grow many, nor can I give the result of my experience with many new kinds. I may just say that for the early crops I use the Black Prince; for the main general crop to supply all culinary purposes, Keens' Seedling—this is succeeded by British Queen and a few others; and for a very late crop I grow the Elton. The last-named supplied us with splendid fruit till after the middle of August. I am told that the Frogmore Late Pine is later and of superior quality to the Elton. This variety, with a few others of high repute, I hope to prove next summer.—QUINTIN READ, *Biddulph*.

NEW ROSES.

"HERE they are again!" List after list comes tumbling in, of beauties of surpassing excellence. "Oh! she's lovely, she's divine!" cries out each enthusiastic grower, as one after another marshals themselves before our admiring eyes; but, alas! opinions differ about beauty. "Eyes blue and black" have their various champions. Some, if we may believe the pre-Raphaelite schools, admire red locks and a tawny visage; others are contented with a "nut brown maid;" and as our neighbours across the water have their notions about beauty, and somewhat different from ours, the *petit nez retroussé* being an especial favourite with them, I often think that they do not consider what we call a good Rose a proper standard of beauty. Year after year dames of high-sounding pretensions, gallant cavaliers, and belted knights come across the water to take us by storm. The freshness of their appearance and the charm that novelty ever has given them a favourable reception; but they gradually drop off, become few by degrees and beautifully less, until at last some half-dozen or so remain with us.

There is one fault, too, to be found with our French friends—viz., that they do not artificially fertilise, they trust to insects; and if they had been more particular on this head I do believe, grand as are the flowers they have sent us, we should have had finer still. And when one desires to know somewhat of the parentage of their children, alas! they can tell us nothing. The pips are gathered, in some instances the names of the mother plants are preserved, but no more, while in England a better plan is being pursued, Mr. Ward, especially, the raiser of John Hopper, being very careful both to artificially fertilise and to preserve the names of both parents. He is now, I believe, very busily endeavouring to infuse some of the Tea blood into the Hybrid Perpetual Roses, and if he succeed he will open up a new era in our Rose gardens.

Out of the lists which have been sent to me I have gathered that there are sixty-five new Roses coming over this autumn. Of this number three are Tea-scented, six are Bourbon, and the remainder Hybrid Perpetuals. Other lists may add more even to this number, but I have culled these from those sent me by two of the best growers, Margottin and Charles Verdier, who, however, neither of them undertake to say anything save of their own seedlings, for these Roses are raised in different parts of France, are seldom seen in Paris, and, therefore, they are as little likely to know anything of them as we are. We are, then, perforce obliged to recur to this—What have these raisers or senders-out done before? what faith can we put in their recommendations? are they good judges? and is their taste similar to ours? I believe this to be the only way in which we can arrive at anything like a proximate estimate of what the new Roses will be. It is the plan we very much act upon in England with regard to other flowers. New lists of Verbenas or Geraniums come out; growers may not have seen them, but they draw their conclusions much in the same way. "Oh! Mr. A. always sends out such a lot of rubbish, one cannot depend on there being anything good amongst them;" "Mr. B. had some good things last year, and I dare say we shall find some novelties amongst them;" "Mr. C., who is he? Quite a new raiser: we must be cautious;" and so on. And so with Roses. Who raised or sent out *Senateur Vaisse*, or *Comtesse de Chabillant*, or *François Lacharme*, or *Charles Lefebvre*, or *Duc de Rohan*, or *Eugène Appert*? Who sent out, amongst Bourbons, *Louise Odier*, or *Catherine Guillot*, or *Louise Margottin*? And I think we shall find that by attending to such a method we shall be more likely to come to a right decision for the future than by listening to all the high-sounding praises that the raisers or senders-out themselves give of them.

Then there is another rule I think we may lay down, that when a French Rose-grower describes a flower as "nearly full" or "moderately full," it will not do for us. And yet once more: when we see a flower sent out at 15*fr.* or 10*fr.*, we may not uncharitably conclude that as they ordinarily charge 25*fr.* or 20*fr.*, that there is something wrong about it. Taking these "canons," then, to guide us, let us examine the lists:—

BOURBONS.

1. Céline Gonod (Gonod).
2. Madame de Stella (Guillot père).
3. Madame Joséphine Guget (Touvais).
4. Reine de Castille (Pernet).
5. Madame Clotilde Perrault (Vigneron).
6. Revérend H. Dombain (Margottin).

Of these No. 1 is described as only moderately full, so I would not augur much concerning it. 2 Comes from a good source, and but for its price (15*fr.*), I should have concluded it to be a desirable variety. 3 Is said to be small; and as Touvais has never given us anything worth much, much is not to be expected from it. Of 4 the same may be said. 5 And 6 are seedlings of Louise Odier, and we may therefore hope are good. Of 6 I can speak from personal knowledge. I saw it growing in Mons. Margottin's garden, and afterwards had blooms sent to me. It is without doubt a fine Rose, and possesses the unusual property amongst Bourbon Roses of being very fragrant. When to this is added that the raiser of it has never sent out a bad Rose yet, and that he has a very high opinion of this variety, we may safely conclude that it will be a great addition. It is of a bright lively carmine, very vigorous and hardy.

And now for the Hybrid Perpetuals. We will take them according to the raisers.

CHARLES VERDIER.

1. Alpaide de Rotalier (Campy), transparent satin rose.
2. Alphonse Belin (Gautreau), clear brilliant red.
3. Joseph Durand (Lédéchaux), slaty, shaded red.
4. Triomphe de Villereynes (Lédéchaux), clear vivid red.
5. Leopold Roi des Belges, clear velvety red.

Of these, none of which were raised by Mons. Verdier, I obtained a prize at the Floral Committee (Comité de Floriculture) of the Société Impériale et Centrale, at Paris in July, 1862; and 5, a prize at Brussels in the same month. 3 Is not full enough. 2 Has the under side of the petals

a different colour—a decided blemish to my mind; while 4 seems from description to be good, a seedling of *Triomphe de l'Exposition*. Of 1, 4, and 5, then, we may entertain reasonable hopes.

MARGOTTIN.

6. Bernard Palissy, vivid carmine red.

7. *Maréchal Forey*, velvety crimson.

The first of these is a seedling from Jules Margottin; the second from *Triomphe de l'Exposition*. This I saw, and a fine noble-looking flower it is. I hope well of both of these.

EUGÈNE VERDIER, FILS AÎNÉ.

9. Claude Mellon, beautiful scarlet.

10. George Paul, beautiful lively red.

11. George Prince, dazzling red; reverse of petals whitish.

12. H. Laurentius, beautiful crimson red, cupped.

13. John Nasmith, lively crimson red, veined with purple and violet.

14. Joseph Fiola, lively velvety red.

15. *La Duchesse de Morny*, beautiful tender rose; reverse of petals silvery rose.

16. *Madame Victor Verdier*, brilliant cherry rose.

Too many, Mons. Verdier, too many; yet he has given us some good Roses—*Prince Camille de Rohan*, Professor Koch, and others. 9 Looks well on paper; so does 10. 11 Has the fault of two colours. 12 Ought to be good. 13 Not full enough. 14, Good. 15, Same fault as 11. 16, Good—that is, so far as description goes.

GUILLLOT PÈRE.

17. *La Reine de la Pape*. (What is the meaning of this?) This variety is said to be a beautiful violet rose.

18. *Mademoiselle Lobay*, bluish.

19. *Pavilion de Fregny*, half white and half rosy purple.

Of these 17 sounds well, and 19 looks like a novelty. Of 18 I do not think much expectation can be formed; but the raiser of *Senateur Vaisse* and *Madame William Paul* deserves the highest consideration.

GUILLLOT FILS.

20. Abbé Reynaud, dark slaty violet.

21. *Amiral La Peyrouse*, dazzling superb red.

22. Eugène Verdier, superb dark violet.

23. *Maréchal Suchet*, beautiful crimson red, shaded with maroon.

24. *Paul de la Meilleray*, purplish cherry rose.

Of these I should say that 20 and 22 are not colours that are suitable for us. 21 And 23 I should hope will be desirable varieties; while 24 with its large petals promises to be an acquisition.

I must for this week close here, for I shall be occupying too much space, and must only repeat that they are conjectural notes save in a very few instances; but were I a grower for sale I should not be at all afraid to take them as I have noted. Time alone can prove whether one's views are right or not.—D., Deal.

AMALGAMATED CHRYSANTHEMUM SOCIETY.—Our readers will have observed an announcement in our advertising columns that this Society intend holding their first Show in the Agricultural Hall, Islington, on the 11th, 12th, and 13th of next month, and we are happy to state that there is every prospect of its being the most extensive Exhibition of the kind which has ever been held. The prizes offered are both numerous and liberal, amounting to £260 in all; and we are informed that, vast as the area is which the Hall affords, there is every likelihood of its being fully occupied.

Arrangements are also to be made for gratifying the ear as well as the eye by an ample provision of musical skill.

A General Meeting of the Society was held on the 12th inst., Shirley Hibberd, Esq., in the chair, when, after the election of several new members, the following gentlemen were chosen as censors at the forthcoming Show:—For Specimen Plants: Mr. G. Smith, Hornsey; Mr. R. Weatherill, and Mr. Walker, Upper Clapton. For Cut Blooms: Mr. Shields; Mr. Croxford, West Ham; and Mr. Taylor, Stoke Newington. For Miscellaneous Exhibitions: Mr. Monk; Mr. Wilkinson, Bow; and Mr. Boff, Ball's Pond. Mr. Cole,

of St. John's Wood, and Mr. Burton, of Mr. Williams's nursery, were chosen to superintend the arrangement of the specimens and blooms to be exhibited.

THE AMARYLLIS.

It would not be easy to calculate how very much the great improvement which has been effected in several sections of our decorative plants within the last quarter of a century, has been stimulated and directed by the various floricultural societies which have been in operation throughout the length and breadth of the kingdom. There is scarcely a class of plants which are capable of improvement by cross-breeding or otherwise, and for which prizes have been offered, that has not been brought up to a stand-point in the way of improvement in size, shape, substance, and colour, so far that any further advance is now almost beyond conception. Take for example the *Azalea*, *Cineraria*, *Pelargonium*, *Pansy*, *Hollyhock*, *Rose*, *Verbena*, &c., and call to remembrance what they were at the time that has been named, and compare them with what they are now, so far advanced on their way toward the ideal of perfection, and it must be admitted that great things have been accomplished. And the improvement that has been attained is not more marked in the superior varieties that now exist than it is in the superior cultivation which has been simultaneously going on. Indeed, it could scarcely have been expected from the varieties and the cultivation that existed at the time referred to that such a high position could have been gained. Few will question that the censorship and prizes offered by the various societies have been among the chief stimulants of the action and enterprise which has accomplished so much. Gardening, therefore, owes a good deal to such societies in conjunction with individual enterprise and public emulation, not only in the way of improved flowers and culture, but also—and largely through such improvement—the promotion of correct taste and a general diffusion of the love and beneficial effects of gardening as one of the most wholesome recreations, both morally and physically, which lie within the reach of a large portion of our population.

Of late years it is pleasing to see the enlarged encouragement which several of our leading societies, both in England and Scotland, have afforded to the *Hyacinth* and other spring-flowering bulbs, which truly may be said to possess a charm peculiarly their own. And on this field of competition combatants have contested the honours with praiseworthy determination, and several of them have covered themselves, shall we say? with a glory, if not so exalted, yet much more innocent and becoming than that of battle-fields.

Bulb catalogues are now as thick as leaves in autumn, and in some cases wonderfully elaborate. One important addition has of late years been made to these catalogues, and it threatens to swell to yet greater dimensions—so much so, that already the *Gladiolus*, to which we refer, is thought worthy of a separate issue for itself. No fault can be found for giving such prominence to so valuable and lovely an autumn flower. The last few years have wrought a wonderful improvement in the *Gladiolus*, and every village society offers prizes for its production, and it forms no mean feature in our autumn exhibitions. If the same rate of improvement goes on for the next dozen years, who can predict the gorgeousness of this flower at that period? Since the days—not very long ago—when *Psittacus* reigned supreme, how great and striking is the advance which has been made!

While almost every society, however obscure and unpretending, offers prizes for the plants to which reference has been made, it is surprising—almost unaccountable—that the *Amaryllis*, which has existed so long among us, should have been next to entirely overlooked by almost all our societies. True, of late years a few nursery firms both in England and Scotland have staged for exhibition some exquisite varieties of this bulbous plant, and many are now talking of the beauty and usefulness of the *Amaryllis*; but still little or no encouragement has come from any of the societies. Without under-estimating either the beauty or general usefulness of any other tribe which meets with a large share of encouragement, it is well known that the *Amaryllis* is not only one of the most beautiful but most

useful and accommodating plants for decorative purposes; and there can be no doubt as to its capability of great improvement. By proper and very simple management it can be had in bloom every month in the year, and wherever placed it never fails to attract attention and to be admired. It has a large share of distinct and striking character to distinguish it; and in spring, when bulbous plants form so large a proportion of the gaiety of the drawing-room and the conservatory, the *Amaryllis* would contrast and vie with any or all of them, and as a flower at the dreary dead of winter it outstrips them all. It is, moreover, a plant which requires but a comparatively small amount of care in the way of potting, &c.; and any one in possession of a pit or warm greenhouse can command it, although it is when expanded in stove heat that the colours come out in their highest pitch of purity. Seeing that it is a plant possessing many good qualities to recommend it, we hope some of our great societies, now that they are busy framing their schedules for another year, will set the example and give liberal encouragement to the *Amaryllis*; and it may be prophesied that it will very soon become a plant of widespread popularity and great usefulness, while, no doubt, its improvement will not be the least noticeable feature in its character. We would be the last to attempt to throw any discouragement in the way of keeping any class of plants before the public; but, as it is evident that all cannot have that amount of patronage bestowed upon them which might perhaps be desirable, would it not, therefore, be wise to lessen the amount of notice which has been taken of and the prizes offered to some given plants, and direct the funds of societies to other objects which have been so long neglected? Say, for instance, that the *Cineraria*, or whatever may be deemed most advisable, should meet with less encouragement now, after the long patronage and the firm hold which it has of the public for certain purposes; and that others, for example, the *Amaryllis*—for which we mean these lines as a good word spoken—should be more liberally and frequently rewarded.

D. THOMSON.

TORRY HILL.

On the northern slope of the elevated ridge of hills which divides the valley watered by the river Len and the creek which separates the Isle of Sheppey from the main land stands the pleasant mansion of Torry Hill, the seat of Lord Kingsdown. The position of the house is sufficiently elevated to command a very extensive view without at the same time being bleak and exposed; on the contrary, the abundance of healthy and vigorous trees gives the grounds and park, as well as the neighbourhood in general, a clothed appearance not usually met with in situations so elevated; while the richly cultivated district over which the view extends is perhaps second to none for general fertility and the good quality of its produce. The gentle and easy slope terminates in the creek or inlet above referred to, and the whole of the Isle of Sheppey, with its verdant fields and waving crops, is entirely brought under view; and beyond, the waters of the Nore with the numerous craft which enter the Port of London may be distinctly seen from the more elevated portions of the mansion. I am also told that the more distant Essex coast may be made out on a fine day.

A situation possessing so many natural advantages may justly be regarded as a fine one; and it is only proper to say that in carrying out the arrangement of the mansion and grounds generally these advantages have been duly made use of. The present spirited nobleman having made it his principal residence, he has remodelled, or, he may be said to have rebuilt, the whole of the mansion during the last few years; and the many qualifications of beauty, utility, and the other matters which form a well-arranged mansion of the first class have been all duly considered. The principal fronts are to the north and east; the latter being the carriage-front, while the former looks over a terrace garden of considerable dimensions, which at the time I saw it was gay with flowers. On the west side and connected with the mansion is a lofty conservatory upwards of 60 feet long by 42 feet wide, while at the north-east angle of the mansion a circular tower is carried up to a considerable height; in this a spiral staircase of more ample dimensions than is usually met with in

such places leads up to the summit, from whence a very extensive prospect of the adjacent country may be obtained. The shipping at Sheerness and the winding serpentine course of the Medway may be traced with tolerable clearness; while the pleasant town of Sittingbourne seems almost within rifle-shot of the place. The offices are connected with the south-western angle of the main building; and the dressed grounds, which are extensive, are mostly on the north, east, and south sides.

Some plant and forcing-houses occupy a walled-in garden on the south side of the mansion, but other glass structures are detached, and differ much in the aspect they present; but as many of the plant-houses are span-roofed, their position with regard to the back wall against which they are placed is of little moment. Suffice it to say that they are all new, or such as have been built in the last six or eight years, and many of them since that time. The large conservatory has not been long finished, and, of course, the permanent creepers, &c., have not yet occupied all the space allotted them; but a plant-stove of considerable size, having a projecting bay in front with a semicircular roof, and facing the east, was well furnished with plants, all of which did well. We noticed that the southern side, which was a blank wall, was wisely taken advantage of to introduce a few Ferns; while the body of the house was well filled with the most popular plants of the day, amongst which were some very fine specimens of *Croton pictum* in excellent health, equally good specimens of *Marantas*, *Alocasias*, *Caladiums*, *Dracenas*; and the many other plants which form indispensable features in a plant-stove had excellent representatives here. In another house were several dozens of that beautiful plant for winter decoration—*Poinsettia pulcherrima*, from 1 to 2 or 3 feet high, the whole, including the shortest, giving promise of flowering well. In another place were Chinese *Primulas* in robust health and knotted for flower; and the other popular plants necessary to furnish a large conservatory were in their various stages of preparation in other houses devoted to that purpose.

The great feature of attraction, however, was the fruits, more especially the Peaches and Nectarines, which, even at the late period I saw them, were magnificent, and those that had ripened earlier in the season had been still better. They were partly grown under glass and partly on open walls; but the latter had the advantage of being flued—a plan well worthy of more general adoption, and the success which has attended it here entitles it to every consideration. The wall appeared to be about 13 feet high; and the face against which the trees were planted, though plain, was nevertheless separated from the back part of the wall by a cavity which formed the flue, the heat from the fire travelling three times the length of the wall, there being partitions to direct it that way. Flued walls are common in the north of England, and the expense in making one is trifling compared with covering a wall with glass; but as I may return to this subject another time, it is needless saying more on that head now than that such walls produced excellent fruit, the trees occupying them from the bottom to the top. Most excellent fruit was also furnished by the Peach-houses or glazed walls, of which there was also a considerable length adjoining those not so covered; and I was told that Peaches weighing 12 ozs. had been gathered in the past season. There were also a few trees in pots, and a house had been accorded to them; but I understood their produce was not so satisfactory, and they were being done away with.

The Grapes in the various houses were also excellent, particularly some *Muscats* of Alexandria, while the *Canon Hall Muscat* was not so satisfactory; but the *Black Hamburghs*, of which there was a great quantity, were excellent in berry and well coloured. I may here observe that a mode of heating the borders of one or more of the Grape-houses intended for early forcing, and which is well worth general adoption, was pointed out to me. I have seen a modification of the plan before, but not exactly the same as is here carried out. The Vines in the houses in question are planted outside; and the borders being higher outside than the tier of hot-water pipes which run along the front, inside near the breast wall, holes are made in the front wall at distances about 5 feet apart; communicating with these holes are drains laid through the border, which is about 12 feet wide, the ends of the drains turning upwards, and

each is furnished with a plug to shut or open at pleasure. These drains are all at right angles with the front wall, and I believe, but am not certain, that they are not connected with each other. The ends entering the house are on a level with the hot-water pipes, and are, consequently, likely to receive the heat imparted by these pipes; while the house can be refreshed with air from the outside, which travels readily enough inwards through the drains when the outside plugs are open. I believe this ingenious contrivance was introduced by Mr. Fox, a former gardener at this place, and it is certainly the simplest method of applying fire heat to a border that has yet been adopted. I am not certain whether the drains through the border are of brickwork or of earthenware piping, but there is no doubt but the latter would do well. Certainly the good quality of the Grapes indicated that their general treatment was good; and I have no doubt that the warmth imparted to a border by means of pipes or drains traversing it as above is much better than when the border is completely celled underneath. The latter plan, having failed in more places than one, is of questionable utility. This subject, however, is deserving of being further inquired into, and it would be well if some who have been successful in heating their borders, so as to secure early Grapes for a number of seasons in succession, would report the mode by which the object was effected. At Torry Hill, I believe, it has not been usual to commence forcing so early as has been done in some places, but the condition of some of the Vines when I saw them showed that they had been tolerably early.

The Pines grown here were mostly Black Jamaica, a kind much less grown in the south of England than in the north. It is, unquestionably, the best winter fruit, but opinion is much divided as to it or the Queen for summer use, the more compact growth, and, perhaps, hardihood of the latter commending it to more general use. At the table the Black Jamaica is as great a favourite with those who partake of it, though not, perhaps, with those that do the decorating, as the crown is often small. This, however, is foreign to the object now in hand, and I have no doubt but the Black Jamaicas are grown at Torry Hill for their good table qualifications. Good Melons were also grown in pits heated by stable-dung, and some Cucumbers in excellent health and bearing well in one of these pits were pointed out as having borne fruit for ten months and as being likely to keep on doing so for some time longer.

In the flower garden I noticed a fine batch of *Centaurea candidissima* doing remarkably well; and Mr. Newman, the intelligent gardener, had a quantity of cuttings of it put in with every appearance of their rooting and doing well. Too much has not been said of this handsome plant, which far exceeds anything in its way that has yet appeared. There were also some compartments in a large bed filled with *Amaranthus melancholicus*, which at the time I saw it left nothing to wish for. In fact, the only drawback to the general well-doing of everything in the flower garden was the *Lobelia*, which had not done so well, and with the exception of *Verbena Purple King*, the other kinds were here, as elsewhere, in most places that I have seen this season, only sparingly planted. *Geraniums* of the *Scarlet*, *Pink*, and *Variegated* sections were in most repute; and as they withstand periods of dry weather, such as we are often liable to have in Kent, without impairing their beauty, it is likely they will maintain their reputation. It is only necessary to add, that the whole was in excellent order, including the turf, walks, flower-beds, and other compartments, and reflected great credit on the worthy gardener and his assistants.

To those interested in the construction and heating of new hothouses, I may state that those at Torry Hill, and they were pretty numerous, were all built of wood, except that some iron was used in the curved roof where wanted. The glass was partly sheet and partly rough plate, some of the latter much thicker than is generally used. The whole were heated with hot water, the cannon and tubular boilers being mostly used. Some useful mechanical contrivances in the way of giving air were introduced, and the workmanship of the whole seemed well done. The lofty conservatory adjoining the mansion and communicating with the drawing-room was constructed so as in some measure to resemble the mansion in the exterior; but this had not in the least interfered with the liberal supply of light, and the admission

of air, as well as the heating, &c., and the plants turned out for permanent purposes showed they were quite at home. The house, I believe, was only finished in the early part of the present summer.

The grounds presented the usual feature of Pinuses of the most approved sorts, including some very good *Wellingtonias*, an excellent specimen of *Picea cephalonica*, and other favourite species, and certainly not the least important thing was a number of *Rhododendrons* from seed that had been sent home from Thibet. The plants, I understand, had been kept in pots for several years, but had eventually been turned out in despair of their flowering, which they have not done yet, although it would be difficult to conceive healthier and more likely plants to do so. Even as evergreens they are handsome, the foliage of some of them being as large as that of the common Laurel but more blunted and the growth slower and more compact, while the buds that are formed, Mr. Newman said, only produced wood in former years, although as stout and plump as the flower-buds of other *Rhododendrons*. Perhaps if grafts were taken of them and worked on stocks of other kinds better adapted to the climate they might be induced to flower. In habit and appearance when not in flower they equal the best varieties our gardens possess, though, as above stated, they differ much from them. Perhaps some one having grown these or similar kinds will be able to throw some light on the subject.

The nearest railway station to Torry Hill is Sittingbourne, which is also, I believe, the postal address; and lovers of ancient fruit lore are told that it was in the neighbourhood of Sittingbourne that the Cherry was first cultivated as an orchard fruit, and some old orchards are still visible in places. Neither is the district destitute of remarkable trees, for at the village of Borden are some fine old Yews, and at no great distance from the same place one of the largest common Junipers that I ever saw was pointed out to me. Its position was not in the dressed ground of a nobleman's garden, but simply in the corner of a field where, however, some lover of old trees had supplied it with a prop to arrest its evident inclination to assume a prostrate condition. The stem, which was quite naked for some 8 or 10 feet, had the proportions of a small timber tree, being about 30 inches in girth at the smallest part, and the top showed those signs of good health that indicated that it was not unlikely to outlive several generations of the human family. The soil was flinty, but I believe chalk was not near the surface.

J. ROBSON.

DAHLIA FLOWERS BECOME WHITE.

WILL you tell me how it happens that about fifty Dahlias, which bloomed well, of various and glowing colours last year, are this season uniformly white to our great disappointment and vexation—for the monotonous repetition of green and white, and white and green in borders on either side of a broad gravel walk is tiresome and melancholy? The gardener protests no change has been made, and that they are the veritable roots which he took up and preserved; and I honestly confess we doubted his word, until, regretting the cold white look to a lady one day this week, I heard that her own took the same sportive turn last season. My friend labelled her roots herself, and knew that the same were planted the following season. But alas! how changed—all cold white!

Pray, sir, may we hope that any of the former rich colour can be restored by any treatment, or, in the common course of events, will they appear in brilliant costume as at first? The Dahlias are all vigorous and healthy-looking; the foliage of a rich dark green colour; the flowers well-shaped and perfect, swarming with earwigs, as they always are, and blooming freely.—AN OLD LADY.

[We cannot possibly believe anything else in your case than that you have been deceived in some way with your Dahlia roots. That fifty Dahlias of different glowing colours should one and all be changed by any process of nature or art is perfectly inconceivable to us. At all events, if such be the case we must confess being perfectly ignorant of what has been the cause or what can restore them from white. Just examine the flowers and foliage, and see if in shape and build the flowers are not all identical, which could not be the case even granting that the supposed change in

colour were possible, which we do not believe. We fear you are the subject of either mistake or deception. Could we believe that Nature would sport or be influenced into such lawless irregularity there is no saying what might be expected. It strikes us that you will find all your Dahlia flowers of the same shape as well as of the same colour, and different varieties of Dahlias are very differently shaped; and surely you cannot believe in change of shape as well as of colour.]

PLANTING.

It sometimes happens that for the purpose of finishing as he goes along a gardener is obliged to move plants in winter or early spring which would be better if they could remain unmoved till the end of April. I was so circumstanced myself once, and had to move a goodly number of large evergreens—Spruce, Holly, and *Lamstinus*, &c., when I would rather have waited till April. It was done, however, in winter and with perfect success—not as much as one death taking place out of about two hundred moved, and all growing in a strong clayey soil with a blue clay subsoil.

Mr. Dawson seems to think that large plants cannot be successfully transplanted in strong soils. Now the above plants could not be less than thirty years old, having occupied the place I moved them from for about twenty-six years.

As a general rule Mr. Dawson prefers small plants, and no doubt where large plantations are to be made no other are available; but where the planting is not too large and large plants obtainable, I confess to a strong leaning in their favour, not only because the desired effect is almost at once produced, but because I have experienced no failures; and, like Mr. Dawson, I have had to do with different soils both in this country and beneath the burning sun of North America.

In the winter of 1855-56 I was engaged planting out the view of a village and a public road which were too conspicuous from a part of one of the approach roads. It took about five hundred plants to accomplish the object: most of these were Oak, Elm, and Sycamore, averaging 15 feet in height, with some large shrubs fronting them. The object was at once effected, and when I saw that plantation four years afterwards it was as dense and as flourishing as if it had been there fourteen years; but if small plants, such as Mr. Dawson recommends had been used, the noble proprietor would no doubt have had to wait that length of time for the desired effect. I may mention, that though highly approving of mulching and the general necessity of watering, none of these trees or shrubs was so favoured, and, worse than all, some of the planting was done during a sharp frost.

If I mistake not there is a general impression in favour of moving the Pine tribe in autumn. I have always practised late-spring planting, and have never had a failure with this tribe. When I could select my own season I have taken them just as they commence growth or are showing symptoms of it. In the spring of 1857 I had to move about fourteen large Spruce; they were at least twenty-six years old, and had to be moved about a mile across the demesne. The work was not commenced till the last week in April, when some of the plants had begun growth. These were all moved with perfect success, all of them making a growth of from 6 to 9 inches the first season. They had a good watering before all the soil was put in about them, but no mulching was given, the spreading branches well securing the roots from the sun.—J. K., *Ireland*.

CELERY.—I fully agree with Mr. Fish as to the superiority of Turner's Incomparable Dwarf White Celery both for autumn and spring use. I had five or six varieties this season, but this kind is the favourite; moreover it is not apt to spindle like some other sorts, and, being white, is useful for cooking as well as for table. For the last three years the Celery did not do well here, it being subject to disease. This season the surface of the ground about the plants had a dressing of superphosphate of lime before earthing-up, which I consider has prevented the disease to a considerable extent. — D. PHELAN, *Gardener, Rathmines Castle, near Dublin*.

HYBRID PERPETUAL ROSES FOR A BED.

A LADY, "MARIE," writing from a central county, asks for information on the above subject. She wants to have dwarf plants on their own roots, and to have them trained in pyramidal form so as never to be more than 3 feet 6 inches or 4 feet high.

It is easy enough to have dwarf Perpetual Roses on their own roots, but to be able to train them so as to be nice-looking pyramids is a more difficult matter; for in spite of all the attention that can be given to Roses, they have a waywardness of their own at flowering time which we fear will prevent their submitting to the close restraint necessary to insure a tidy uniform shape of the kind wanted at all seasons. Perhaps our correspondent is anxious for a bed of Roses to resemble such masses of plants as are to be seen in pots at the London shows. This, no doubt, could be done, but such plants only conform to the pyramid or balloon shape shortly before the blooming period; their growth the preceding summer is irregular and straggling enough, and cannot well be made otherwise if flowers are wanted. We would, therefore, advise the lady to abandon the idea of exact training during the growing season, merely cutting away any gross shoots, and, at the proper time, to prune as ordinary dwarf irregular-growing plants, for the Rose looks best so done. There is a difference in Hybrid Perpetuals for doing well on their own roots. Those we have found succeed best are Baronne Hallee, Baronne Prevost, Caroline de Sansal, Jules Margottin, Géant des Batailles, Souvenir de Reine de l'Angleterre, William Jesse, and others; while Oriflamme de St. Louis, Sénateur Vaisse, and some others have not done well. In another place, however, this may not be the case; but whatever kinds our correspondent selects we certainly do not by any means advise them to be trimmed like clipped Yew trees in summer.—J. R.

THE WALNUT TREE.

A CORRESPONDENT complains that a Walnut tree of his growing in a meadow on a gravelly soil overlying chalk has never produced Walnuts until this year, and now they are poor in quality, and far from numerous. The neighbourhood, he observes, is one certainly not unfavourable to the Walnut; and the tree, which is about 30 feet high, was rather severely root-pruned last year. This season most of the fruit fell at an early period of their growth, and the remainder were only very poor. He asks for information on the subject, advice as to the future treatment of the tree, and other particulars, remarking that the culture of the Walnut has not been adverted to of late in *THE JOURNAL OF HORTICULTURE*.

I may in the first place observe, that the Walnut is seldom considered as in the list of cultivated fruits, its growth and bearing being generally left to chance. There is an old distich coupling the Walnut with a spaniel and a wife, to the effect that they are all better of being well beaten. Now, this advice is, I confess, all that I have read about rendering the Walnut tree fruitful; and vulgar though it be, and often regarded as an unmeaning couplet put forth by some sarcastic individual, I am far from denying it some merit, for the beating of the tree with long poles to knock down the fruit in autumn, is never accomplished without breaking off a number of small shoots, thereby effecting a sort of rude pruning, and so rendering the tree more fruitful the following season; and as the rougher the usage the more shoots are broken off, it is not unlikely that a greater proportion of fruit may follow the year after. This, however, is not always the case, for other influences also operate on the crop. An unfavourable spring is fatal to the setting of the young fruit, or it may be an ungenial autumn refuses to prepare the embryo buds, or other causes may tend to produce a failure similar to that which all other fruit-bearing trees are liable to.

Now, although but little can be said about the proper treatment of the Walnut tree, I fear the severe root-pruning given by our correspondent last year is the cause of much of the fruit falling at an early stage, and of the remainder being poor and imperfect, as most likely the tree would have borne a fair crop of useful fruit but for that pruning which deprived it of its most important food. It is

possible, however, that next season, or the one after that, the tree may be benefited by the operation, especially if it is young and vigorous; but in general we would not advise root-pruning Walnut trees unless they are in that condition, for Nature usually points out when a tree ought to commence bearing, and if it begins to do so when very young, and is allowed to carry heavy crops, it seldom arrives at a great size. To begin bearing early is, in a certain sense, a token of disease or a too early maturity. Pinuses which commence bearing cones early rarely become large trees, and the same may be said of Walnuts. Patience, therefore, must be observed, and the best results will usually follow when the tree has been allowed to have its own way in everything save in the site chosen for it, which ought to be dry, hard, and stony, avoiding the deep, rich, cultivated soils of old gardens, and the damp situations to be met with elsewhere. The most fruitful Walnut trees are very often those occupying a public place on some hard road or thoroughfare, or some dry meadow, the tree receiving no further attention than a good beating when it produces fruit. At all other times letting alone is, perhaps, the best treatment the tree can have.

It may here be remarked, that although there is only one recognised species of fruit-bearing Walnut in general cultivation, the kind called French being only a sort of enlarged English, still, like every other hardy fruit, it differs to a certain extent on being raised from seed; the variation takes place in the quality of the fruit, so that certain trees produce better nuts than others similarly placed. This fact is well known amongst the rustics, who have for many years made it a point of duty to taste the produce of all.

A similar sport or variation is observable in the Sweet Chestnut, and other trees also raised from seed. Some are known to produce excellent nuts, others indifferent, and some cast them before they arrive at perfection. Other instances might be given, but in your own case I would advise the Walnut tree to be left alone, and when Nature has done her part by expanding the tree to something like the proportion of a timber tree, she will afterwards become less anxious for enlargement, and direct her energies to the production of fruit.—J. ROBSON.

A PLEA FOR FLORISTS' FLOWERS.

In the columns of a contemporary I find a paper bearing the honoured signature of Robert Fortune, in which, fresh from feasting his eyes with Japanese beauties and gardens of ten thousand Cherry trees, he runs a tilt at florists as having to some extent injured floriculture. This is an old charge, but one hardly expected it from this quarter; for when Mr. F. looks at the beautiful collection of *Pompone Chrysanthemums*, and remembers that they were the progeny of the little *Chusan Daisy* which he imported into England, he will acknowledge, surely, that in this instance florists have done a good service. But indeed it is hardly fair to put the case thus, for he allows that they have frequently benefited floriculture, but thinks that, in some instances, they have carried their principles too far. We will not contend about that, as it is, after all, a matter of taste; but I think he has hardly made out his case with regard to Fuchsias, the new kinds of which he characterises as "being a new race of sickly-looking things with large gorged flowers and unhealthy-looking leaves." As I met Mr. Fortune at the last Royal Horticultural Society's Exhibition in September, he may have possibly formed this conclusion from the few which he saw there; but these were simply plants of Messrs. Smith's new decorative Fuchsia *Pillar of Gold*, about which there are certainly different opinions, although I believe myself that it will make a very desirable plant for table use, and also an addition to ornamental plants. But no one ever intended to set that forward as a florists' flower, and I do not think that the charge of sickly-looking foliage can be brought against the new kinds of Fuchsias generally. The blood of some of the more vigorous species has been infused into them, and I have seen many of the named kinds, not merely in pots but out of doors, with as fine foliage, large, glossy, and green, as any of the older kinds which he enumerates. I am an admirer of many of them, *gracilis*, *globosa*, and some others being very pretty ornaments for

the flower garden; but these "artificial monstrosities" make quite as good bushes when any ordinary amount of care is bestowed on them, while, in point of freeness of flowering, there can be no comparison, many of the new kinds absolutely weighing down the branches with the weight and number of their blossoms.—D., Deal.

MILDEW ON VINES IN A CONSERVATORY VINERY.

ADJOINING our drawing-room is a good-sized greenhouse, and when we took possession last June twelvemonth, there was a magnificent crop of Grapes coming on. Very soon, however, mildew appeared to a considerable extent, and we were advised to try sulphur, which we did with such success that the next morning every leaf was dead, and every bunch of Grapes (above six hundred) was shrivelled to nothing. In despair we cut off all the leaves and bunches, and in three weeks' time a fresh crop of leaves came out, but no more Grapes. All through the winter we followed the instructions given in *THE JOURNAL OF HORTICULTURE*, gave plenty of air, and thoroughly washed the house and the Vines with soap. In the spring the Vines broke well, and soon had an abundant crop of Grapes; but, alas! when they became the size of currants, the mildew again appeared, covering them with a thick white powder, and each berry cracked and withered up, so we have again lost our crop. But the provoking part is, that the mildew seems to affect everything in the greenhouse. The Geraniums lose their leaves, and will not blossom; the Fuchsias are perfectly bare, and nothing prospers. The smell of the mildew is quite overpowering. I should add that the Vine had always been noted in the neighbourhood for bearing well, and that the previous tenant, who is also the landlord, had a remarkably fine crop of Grapes the year before last from the same Vine. We have been advised to do away with the old roots, and plant new ones, but as we have only a seven years' lease it would scarcely be worth while to go to such expense, if in any other way we could prevent the evil. The Vine has been in bearing for more than twenty years.—SIGMA.

[There are two points we should have liked to have known more about—first, the mode of applying the sulphur; and, secondly, the mode of heating the greenhouse. As to the first, we can only imagine from the results that you must have burned the sulphur, whilst, to apply it correctly, it should only be dusted on the fruit and leaves affected. From what you state, we think it would be wrong to destroy the Vines; but you might dig a deep trench for a drain in front of the border. We would care less about the flowering plants now, but do everything by dryness and extra heat to harden the wood of the Vines. When this is done, and the wood is brown and hard (but not if at all soft and spongy), and the leaves are turning brown, we would shut up every cranny that connects the house with the drawing-room, using damp moss, clay, or putty, for the purpose. Then, we would burn in the house from a pound to half a pound of sulphur mixed with sawdust. This will settle all fungus matter, as well as all insects; but, of course, the fumes must be kept out of the drawing-room. If not sure of the wood being hard and ripe, do not try this cure, but whether you do or not, proceed as follows:—When Vines are pruned, wash the glass and wood with hot soap and water, not soft soap; then wash the Vines, scrubbing them well with the same, removing all loose bark, &c. Paint them all over then with clay and sulphur paint; wash all the walls; paint with lime and sulphur, and as the Vines break go over the walls again with sulphur, especially where the sun strikes on the wall. To make it stick use a little fresh lime with it, or make a paint with the sulphur, by using some oil. Scrape off the surface soil of the floor, and replace with fresh. Now, these are all first-rate precautions, but alone they will not save you from the enemy. We incline to think that the reason why you have suffered so terribly is, that you have kept your house too close in the growing season in summer, and the atmosphere too moist. If your house is heated by hot-water pipes, we would also smother them with sulphur as soon as the Vines broke. From the beginning of June we would leave a little air on

night and day at the back of the house at top, and if this cooled the house too much, we would use fire to keep up the temperature. We would use as little watering in the house as possible, and by July we would remove all except a few favourite specimens out of doors. With a drier atmosphere and more air, we think you will see no more of your enemy; but if a berry or a shoot be affected, dust it with flowers of sulphur at once before the disease has a chance to spread. With a drier atmosphere and a greater circulation of air in summer, we do not think you will be troubled after these precautions.]

CULTURE OF THE GENUS IMPATIENS.

THE species of this genus are as useful as they are singular. Some flower freely at most seasons of the year, and are good ornaments for our stoves in winter, especially the two small species—*latifolia*, bright purplish-rose colour; and *latifolia alba*, white. They are also very serviceable as cut flowers in a bouquet or in a vase for in-door decoration.

They are very readily grown by a simple stove treatment. We have been very successful with them by placing cuttings of the smaller varieties in the early spring, three into a large 60-pot, in a mixture of sandy peat, keeping them close for a day or two. They readily root, and should receive moderate shifts into a mixture of four parts good fibrous peat, one of sand, and one of loam, with a good sprinkling of well-broken potsherds. The cuttings should be kept constantly stopped where a tendency is shown to become too lanky, to which they are rather liable, or when good round plants are desired and not immediate flowering. These small varieties will, if kept well in the light and not too liberally and loosely shifted, flower at almost every joint.

The larger varieties, such as *Hookeri* and the beautiful *Jerdoniae* especially, will at all times flower better when, as young plants, they have been constantly kept pinched back, thus making them as short-jointed as possible. Take pains, however, to give them all the sun and light compatible with a general stove routine. Do not stop them after midsummer, and whilst you encourage a robust growth take care not to supply them with too much water, and they will in their beautiful blossoms amply repay all pains taken.

There are numerous sorts. *Impatiens flaccida*, *Jerdoniae*, *Hookeri*, *latifolia*, *latifolia alba*, *biflora*, *coccinea*, and *tricornis*; and a once-acknowledged very pretty variety, *Impatiens scapiflora*, having a rather large, light flower, tinted with rose colour, and with leaves more ornamental than most of the others. Besides these there is our own hardy *Impatiens Noli-me-tangere*, the Touch-me-not of Britain.—WILLIAM EARLEY.

HARDY AQUATICS.

(Continued from page 249.)

ACTINOCARPUS DAMASONIUM is a pretty little perennial, growing in British ditches; has white flowers from June to August.

RUMEX HYDROLAPATHUM (Water Dock) is a noxious weed in many places, but highly ornamental, nevertheless, in others; grows 6 feet high, having a long spathe of green inflorescence in July and August. *R. acutus* (Sharp-leaved), growing 2 feet high, and *R. aquatilis*, attaining a height of 5 feet, are native plants found in ditches and sluggish streams. The flower-spike or spathe of these plants should be cut before the seeds become ripe, or it is apt to be borne along by the floods, and may cause serious mischief to the meadow lands adjoining rivers.

BUTOMUS (Flowering Rush).—*B. umbellatus* to my thinking, and I may say by general consent, is the handsomest of British plants. It grows 2 feet high, erect; leaves long and sharp-edged; flowers pink, but assuming different shades of red, produced in umbels upon a long stalk. A perennial, flowering in June and July. Found in ditches. *B. latifolius* has broad leaves, and white flowers in June and July. A perennial from Nepal, growing a foot in height.

ACORUS CALAMUS (Sweet Flag).—A native reedy plant inhabiting pools, growing 2 feet high. The leaves are highly aromatic, a quality which they lose in drying. The flowers are apetalous, appearing in June and July.

SCIRPUS (Club Rush).—*S. lacustris* (Tall) is a reedy-like

plant, growing 6 feet high. England; rivers. *S. rufus* is a curious little grass-like perennial, growing 6 inches high; found in Scotch waters. There are several more, but of no interest except to the botanist.

ISOLEPIS FLUITANS is a curious perennial floating Grass, flowering in July and August, but apetalous. Britain; ditches.

IRIS PSEUD-ACORUS.—Flowers yellow, produced abundantly in June and July. Grows 3 to 4 feet high, having a stately reed-like appearance. This is a perennial, growing equally well in the water as in moist places. Britain. *I. fetidissima*, the leaves of this species rubbed between the fingers emit a fetid odour; the flowers are lead-coloured, produced in June; grows 1½ foot high. *I. fetidissima variegata* is a highly-ornamental perennial. The last two require to be planted at the margin of the water. There is a pale-yellow variety of the Bastard *Acorus*—viz., *I. pseud-acorus pallida flava*, similar to the species.

RANUNCULUS (Crowfoot).—*R. hederaceus* (Ivy-leaved), *R. obtusifolius* (Blunt-leaved), *R. tripartitus*, *R. pantothrix*, *R. pantothrix flaviatilis*, *R. pantothrix caespitosus*, *R. aquatilis* (Water), *R. aquatilis peltatus* (Peltate-leaved), are all pretty plants. Some have the leaves submerged, variously divided, some multifid, others three-parted. All grow about a foot high, having white flowers, produced abundantly in the early part of summer. Natives of Britain and Europe generally. *R. lingua* (Tongue-leaved), is a curious yellow-flowering deciduous herbaceous plant, growing 2 feet high, inhabiting muddy ditches, and flowering from June to August. *R. alpestris* (Alpine), a Scotch species, is a pretty little plant growing about 6 inches high, having white flowers from June to August. *R. polyphyllus* (Many-leaved), is a curious yellow-flowering annual aquatic, growing 9 inches high; flowers in May and June. From Hungary.

SWERTIA PERENNIS, an upright-growing perennial, grows a foot high, and has purple flowers in July and August. Is a native plant, found in marshes.

CALTHA (Marsh Marigold) *C. palustris* (Common Marsh), and *C. palustris flore pleno* (Double-flowered), grow about a foot high, and have yellow flowers in May and June. *C. radicans* (Rooting), is an evergreen creeping aquatic, growing 6 inches high in Scotch marshes, and has yellow flowers in May. *C. minor*, *C. parnassifolia* (Parnassia-leaved), *C. asarifolia*, and *C. biflora* (Two-flowered), are all of low growth, with yellow flowers in early summer, except *C. biflora*, which has white flowers from May to July; the first is a native plant, the second and last are North Americans. *C. flabellifolia* has yellow flowers in May, grows a foot high, and is from North America. *C. leptosepala*, from the same continent, has white flowers in June, and grows a foot high. *C. natans* (Floating), has white flowers in May and June, and is a princely refugee from the Siberian waters.

TEUCRIUM SCORDIUM (Water Germander), is a pretty little plant, growing 3 inches high, with rosy purple blooms in July and August, and is a native plant found in marshes.

HYDROPELTIS PURPUREA is a floating-leaved perennial, with reddish-purple blooms in July and August; has peltate leaves, and is from North America.

CALLITRICHE (Water Starwort).—*C. verna*, *C. verna aquatica*, and *C. autumnalis* are annuals, growing in ditches, about 3 inches high, with white flowers, but little less than weeds, though pretty.

MENTHANTHES (Buck Bean).—*M. trifoliata* (Three-leaved), a highly ornamental native species, grows a foot high, and has white flowers in July. *M. americana*, with trifoliate leaves, grows a foot high, having white flowers in July, much resembling our native species. It is from North America.

LYSIMACHIA (Loosestrife).—*L. thyrsoiflora*, grows 1½ foot high, and produces yellow flowers from May to July. Britain; lakes. *L. nemorum variegatum* is a pretty trailing plant growing in wet places, and has yellow flowers from May to July. *L. vulgaris*, with yellow flowers from June to September, grows 3 feet high, and is found in wet places.

HOTTONIA PALUSTRIS (Water Violet), has finely-cut leaves all produced under water; the upright flowering-spikes appearing above the water, with their whorls of flesh-coloured flowers, have a very beautiful appearance. It is a perennial, growing in ditches, is about a foot high, and flowers in July and August.

THALIA DEALBATA, a half-hardy plant with mealy stems,

growing 4 feet high; has blue flowers in July and August; from South Carolina. Probably quite hardy.

HIPPURIS VULGARIS (Mare's-tail) is an interesting native perennial plant with apetalous flowers, appearing in May and June; grows in ditches.

VERONICA (Speedwell).—*V. beccabunga* (Brooklime), is a pretty native plant, producing an abundance of bright blue flowers throughout the summer months. *V. caroliniana*, from Carolina, has blue flowers in June and July; grows a foot high. *V. anagallis* (Pimpernel-like), and *V. scutellata* (Saucer-leaved), grow from 1 to 2 feet high, having blue flowers in July and August. They are native plants, found in marshes. *V. parvularia*, from the South of Europe, grows a foot high, and has red flowers in July and August.

UTRICULARIA.—*U. vulgaris*, *U. minor*, and *U. intermedia* are curious little plants growing 6 inches high, producing yellow flowers in June and July. All are natives.

ALOPECURUS GENICULATUS is a rather pretty Grass, growing a foot high. A native plant.

PHALARIS AQUATICA (Water Canary Grass), grows 1½ foot high, and is an annual. From Egypt.

DEGRAPHIS ARUNDINACEA is a fine reedy-looking perennial Grass, growing 3 to 4 feet high. *D. arundinacea variegata* has leaves striped with white, and is highly ornamental; grows luxuriantly on the margin of rivulets.

CATAEOSA AQUATICA and *C. viridula* are curious Grasses growing 1 foot to 1½ foot high; the former is a native plant, growing in rivulets.

ARUNDO DONAX (Water Reed), is a stately plant, growing 10 feet high, from the South of Europe; and *A. donax versicolor* has striped leaves, and grows 3 feet high. They are highly ornamental near water.

PHRAGMITES COMMUNIS (Common Reed).—A very fine Grass, growing 6 feet high. Britain; ditches, and river-banks.

GLYCERIA FLUITANS is a floating Grass, growing 1½ foot high. Britain; ponds.

HYDROCHLOA AQUATICA and *H. arundinacea* are also reed-like Grasses, growing 6 feet high. The former is a native plant, the other is from the Caucasus.

ERIOCAULON SEPTANGULARE is a curious little plant, with white flowers in September. Found in the bogs of Scotland.

PROSERPINACA PALUSTRIS grows 1 foot high, and is from Canada; *P. pectinata* grows about 6 inches high, and is from North America. Both are annuals, and have white flowers in July.

TRAPA (Water Caltrops).—*T. natans*, an annual, has white and purple flowers in August. It is of floating habit. Europe. *T. bicornis*, a half-hardy perennial from China, has white flowers in June and August.

POTAMOGETON (Pond Weed).—All are floating plants; found in the rivers, ditches, and lakes of Britain. They are curious rather than ornamental. There are nearly a score of species, some with green, others with red, and some with purple and olive-coloured flowers in July and August.

TILLEA AQUATICA is a diminutive annual, with purple and red flowers from June to August. From northern Europe.

MYOSOTIS.—*M. palustris* is a very pretty native plant, growing a foot high, with blue and yellow-eyed flowers during summer, well known as "Forget-me-not." *M. caespitosa*, also a British plant, is of less growth, with pretty blue flowers in June and July. *M. caespitosa macrocalyx* is a long-calyxed variety of the species, with blue flowers in June and July. They are found on the margin of water.

LOBELIA.—*L. Dortmanna* grows erect, and is a perennial with long loose spikes of blue flowers in July and August. It is a native plant, growing 1½ foot high. *L. inundata* is a pretty half-hardy aquatic, growing half a foot high, producing a profusion of blue flowers in June and July. It is from New Holland. *L. tupa* is a splendid herbaceous perennial, growing frequently 8 feet high. It has scarlet flowers in September and October. From Juan Fernandez in the South Pacific Ocean. It requires protection in winter. *L. paludosa*, from North America, has blue flowers in July and August. It is a marsh plant, and a perennial, growing a foot high. There are several more that are semi-aquatic, as *L. cardinalis*. In fact, most of the deciduous herbaceous species are best treated as half-aquatics.

PAENASSIA.—*P. palustris* is a pretty little plant 6 inches high; it has white flowers in July and August. Britain;

bogs. *P. parviflora*, *P. caroliniana*, and *P. asarifolia* are very pretty plants, attaining the same height and having white flowers during the summer months. All are from North America, and grow in still water or bogs.

DROSERA (Sundew).—*D. rotundifolia* has white flowers, and is one of the prettiest of native plants. *D. longifolia* and *D. anglica* have white flowers with delicate rays of red interspersed. They are found in turf bogs, and grow but a few inches high. *D. americana*, with white flowers, and *D. linearis*, with purple blooms from June to August, are remarkably pretty plants, as difficult to grow as they are handsome. *D. filiformis* is a somewhat taller species from New Jersey, having purple flowers in May and June.

ALDROVANDA VESICULOSA, a curious Drosera-like plant, grows but 2 or 3 inches high, and has white flowers from June to August. It is from Italy.

PONTERDERIA CORDATA and *P. angustifolia* grow 2 feet high, having blue flowers from June to August. They are North Americans.

ORONTIUM.—*O. aquaticum* is a curious little plant with apetalous flowers in June. North America. *O. japonicum* grows 2 feet high, having apetalous flowers from January to April. From Japan.—GEORGE ABBEY.]

(To be continued.)

SOME OF THE GARDENS WORTH SEEING.

CHESHIRE.

Name.	Proprietor.	Gardener.	Station.
Withington Hall	J. B. Glegg, Esq.	Mr. C. Allen	Chelford.
Astle Park	J. Dixon, Esq.	Mr. J. Wallis	Chelford.
Alderley Park	Lord Stanley of Alderley	Mr. Royle	Macclesfield.
Capesthorpe Hall	Davenport, Esq.	Unknown	Macclesfield.
High Leigh Hall	G. C. Legh, Esq., M.P.	Mr. Harley	Knutsford.
Beimont	Mrs. Leigh	Mr. McIntire	Northwich.
Marbury Hall	Mrs. Smith Barry	Mr. White	Northwich.
Vale Royal	Lord Delamere	Unknown	Northwich.
Liscard Hall	H. Littledale, Esq.	Mr. Smith	Birkenhead.
Oulton Park	Sir P. Grey Egerton, Bart.	Mr. J. Willis	Tarporley.
Arley Hall	P. Warburton, Esq.	Unknown	Northwich.

DURHAM.

Brancepeth Castle	Lord Boyne	Mr. Dale	Durham.
Auckland Castle	Bishop of Durham	Mr. Miller	Auckland Cstl.
Widestone Hall	Sir W. Eden, Bart.	Unknown	Durham.
Whitworth Hall	Unknown	Mr. Moles	Durham.
Sikworth	Col. Backworth	Mr. Miller	Sunderland.
High Barns	— Pemberton, Esq.	Unknown	Sunderland.

GLOUCESTERSHIRE.

Piercefield Hall	— Clay, Esq.	Unknown	Chepstow.
The Haigh	Dr. Carr	Mr. Arnold	Newnham.
Berkley Castle	Lord Fitzhardinge	Unknown	Berkley.
Lydney Park	Rev. W. H. Bathurst	Mr. J. Witter	Lydney.

I think there is a pretty place in DERBYSHIRE which ought not to be omitted, and quite a public one too, as it is thrown open every summer by the worthy proprietor, and is admired by thousands visiting Matlock, —J. W.

Willersley Castle. P. Arkwright, Esq. Mr. Thornton Matlock.

Chillingham Castle	Earl of Tankerville	Unknown	Wooler.
Dissington Hall	— Collingwood, Esq.	Mr. Cook	Newcastle.

TO PREVENT POISONING BY LEAD PIPES.

LEAD is soluble in pure water. A solution of lead is highly poisonous. There are cases in which pure water, drawn through leaden pipes or from leaden cisterns, has carried a sufficiency of lead in solution to poison a whole family. But a plea of exemption may arise from those who have not pure water. To such we would reply—Impure water coats the lead, in process of time, with the white film of a carbonate of the metal, which is insoluble, with exceptions; one being the presence of water containing carbonic acid. Such water, in passing through the carbonate of lead, takes up an equivalent of the same, which equivalent may be sufficient to cause distinguishable colic, or set up a non-traceable source of indisposition through a whole family. We now approach the termination of our summary by answering a query that may be put by some septic: How is that, after all, some lead pipes do not poison water? It arises from the fact that

old age has wrought a change for the better in their disposition; for when water impregnated with sulphur salts has for a long time passed through leaden pipes, or has long acted on leaden cisterns, the lead becomes coated with a sulphate or a sulphide; and sulphide of lead, being perfectly insoluble in pure water, and equally so in water not too excessively charged with foreign matters to be potable, renders the leaden vehicle perfectly harmless, and thus perfects it for the duties which in all other respects it performs in such a utilitarian manner. But we have a moral to append to our subject. Are we to wait content to be poisoned until our pipes become transmuted, or what are we to do? The remedy is said now to be easily attainable without waiting. Dr. Schwarz, a chemist of Breslau, has made a discovery that cannot be too highly esteemed in a sanitary point of view; which is, that by passing a hot solution of the sulphide of potassium through leaden pipes, the interior face is transmuted from the metallic state to that of a sulphide in a few minutes, at a cost too insignificant to mention. If, then, the need of some change in our water-conduit be satisfactorily shown (and we have endeavoured to do this for years), and the change proposed is based on equally well-known scientific truths, if water in the mines of galena, the sulphide of the noxious metal, be drunk with impunity, let us by all means see that for the future, at any rate, our pipes and cisterns be no longer silent poisoners, but made to support the character they have hitherto not fully deserved, of useful auxiliaries to the requirements of daily life.—(*Builder.*)

CONSTRUCTION OF GLAZED HOUSES FOR GARDEN PURPOSES.

A GENTLEMAN wishing to enlarge his garden establishment employed a well-known horticultural builder to construct a vinery and Pine-house. About the construction of the house I have nothing to say, but what I wish to solicit your advice upon is the gardener's part of the business—namely, the arrangement of the houses for their respective occupants.

I herewith send cross sections of both houses. The soil on which the houses are built is a very stiff, wet, yellow clay.

Fig. 1.

Fig. 1 is the vinery. To make the border, 1, the old soil was taken off to the depth of 4 feet, the bottom was concreted, a wall built all round to keep the roots in, and drains laid to take away all superfluous wet. 2 Is a stage for plants, which runs across both ends and along the middle. 3 Are walks. 4, Upright slabs of slate let into iron posts 2½ feet deep at the highest part of the ground, but getting deeper as the ground falls, to keep the houses on the level. There was about 6 or 8 inches of brick rubbish put upon the concrete for drainage. The soil for the border consisted of about one-third very light fibry loam, one-third yellow loam without any fibre, and one-third of about equal parts of mortar rubbish and very rotten dung almost reduced to black mould. The soil, after being turned over and mixed, was wheeled and shot upon the drainage without any turfy or other loose stuff being put in to keep it from washing among the drainage, and the whole of it was put in at once.

Now, my idea is that in a few years the soil will wash in among the drainage and choke up the drains, so as to cause the Grapes to shank. There is an old vinery near, where the Grapes are much given to shanking; and the border being surrounded by wet, heavy, cold clay, will be colder and damper than it ought to be if the Grapes are required to hang any length of time or if early forcing is intended.

Fig. 2.

Fig. 2 is the house devoted to the culture of Pines. 1 Is the pit where the Pines are plunged, the dots across show where is the bottom of the tan; 2 are three hot-water pipes which are covered with brick rubbish, 3, up to the dots. 4 Is a stage originally intended for Orchids, but as the house is raised so high above the ground level, 7, it is impossible to keep the atmosphere moist enough for them, none of the hot-water pipes being cast with a trough to hold water. The gardener has had some zinc troughs made to fit on the top of one of the pipes, but on account of the rims that encircle the pipes the troughs do not touch, consequently the water is scarcely ever warmed; 5 is the walk which goes across both ends and along the front of the pit; 6 are the upright slates, which are here upwards of 5 feet deep.

In the present arrangement of the Pine-house the tan is fully 5 feet deep, and that body of tan put together new would get so hot that the roots of any plants plunged therein would be quite burnt up, unless it were allowed a month to cool, and that would be a great waste of time. Besides, in a year or two the tan would become rotten, and the best conceivable place for worms; they would reproduce themselves by thousands. Also, as it is a usual practice to repot Pines as early in spring as the weather and circumstances will permit, by the time the sun gained power the plants would be nearly burned up, and the house being so very dry and not shaded at all, they would soon be worthless.

Fig. 3.

Fig. 3 is the same house as fig. 1, but I propose making it the Pine-house. My method is to supply bottom heat with hot water. 1 Is tanner's bark used for plunging, which I

would have 2 feet thick; not more. The bottom heat to be kept up by the pipes underneath, 3; and as screw valves are used the heat could be regulated to the greatest nicety. I propose having a tank, 4, to hold water for the pipes to run through, and to be filled or emptied at pleasure. The tank and pipes to be covered with rough slates, 2, resting on brickwork, and chinks left to be covered with old matting or some such material, and here and there a tin chimney to let the steam out into the body of the house when required. The pit to be 9 feet wide instead of 8 feet, as in *fig. 2*. Some might say that the pit would be too wide to render watering convenient, but that may be managed by leaving a little more room between the back row and back wall for laying a board on the bark to walk on; and by having a long rod to draw the foliage forward, the two back rows might be easily reached.

Fig. 4.

Fig. 4 I propose making a viney; the advantage it has over *fig. 1* for that purpose is very great. In *fig. 1* about 75 yards of clay were wheeled away. Here there is no occasion to wheel away any. The concrete may be laid upon the surface of the ground, and a drain, laid along the front of the house into a drain that runs near, would take all the superfluous water away. I propose that the border be made only inside the house at present. The slates not reaching quite to the ground, some narrow ones were screwed on to make them wide enough; consequently the narrow ones can be taken off at any time, and 4 or 5 feet added to the border along the front whenever the Vines require it.

It appears to me that there has been such a waste of labour and such ignorance displayed in the arrangement of these houses that I am induced to write to you to ask your opinion.—W. H.

[We are always ready to admit gentlemanly criticism, but we must also guard against our pages being made the vehicle of one-sided statements, and that by a second party, especially when the charges of "waste of labour" and "ignorance" are so broadly stated. On this account we suppress all names. We could not join in the charge of "ignorance" without being made acquainted with all the circumstances, as neither hothouse-builders nor gardeners can do at all times as they like. For instance: We have long advocated the planting of Vines inside of a house. Almost all of ours are planted outside, and we know full well that the making such internal arrangements as would permit of planting the front Vines inside is not to be thought about. We believe we could as easily have a new house as alter the old one. Again: We have recommended borders above the ground level, as advocated by our correspondent, in all such circumstances as he describes, but gentlemen cannot always be made to see as the gardener does. Not long ago we were consulted on this very subject, and in the long run the decision came to was this—"You may go as deep as you like, I will give all the labour necessary for moving earth, but I must not have a bank or border a bit higher than the rest of the ground. I could not endure it." And so at extra labour and expense the work was done much as our

correspondent describes, only after draining and concreting there were 16 inches of rubble instead of 8, placed over the bottom, and the finest on the top—a matter of more importance than a layer of open turf, as that soon rots. The drains are not shown by our correspondent, but at that depth there is little chance of their being choked up. With secure drainage and walled-in all round, there would be little danger from the damp cold clay. Even in his own case he will have clay beneath his concrete, and the damp will rise, at least we have found out no means of preventing this. We once had a Vine-border made waterproof on the surface for four years, and yet when broken into it was moist enough. Though agreeing, therefore, that No. 4 is a better mode than No. 1, we could not come to the conclusion about ignorance, unless we knew all the facts of the case. With such proofs of go-aheadism we are surprised that the position of the six pipes has been left undisturbed, even if the stages were to remain as proposed. Neither are we sure where the Vine-stems are to be. If in front, such a stack of pipes is rather near for them. We approve of the inside border being made first; but though this seems very reasonable, borders will no doubt continue to be made all at once, not so much from "ignorance" as from the fact that if not made then they will not be likely to be made at all. There are vast numbers of good employers who hate everything like changes, and who when they agree to a thing being done will insist on having it done at once, but "There must be no more bother about it; mind that, let it be done with."

Now, we confess that without further knowledge we are unable to discern the reasons why, in the Pine-pit (*fig. 2*), the bottom of the pit should be on the ground level (but that should not be the case,—a few inches below the pipes, three, would be deep enough), and the path and the pipes so far above it; nor yet why in the original design, or in that proposed by our correspondent, there should be a slate in front instead of a wall to keep heat in and cold out, and which is better than a slate of ordinary dimensions whose very colour, unless painted whitish, renders it such a good radiator. But, though we are ignorant of the reasons why such an elevation of the floor should have been made, we do not see, now that it is done, what great improvement is given to us in the section No. 3, which could not be obtained by taking 18 inches or 2 feet off the front of the wall of the pit behind the pathway, as in such pits close to a pathway the plants will be more out of the way if the pots are at least 6 inches below the front curb of the pit. It is true the bed in No. 3 will be a foot wider than in No. 2, but that will be no advantage; and there will be six pipes instead of three for bottom heat, and these will be placed in a tank to be filled or emptied at pleasure, involving not "ignorance," but a considerable extra "outlay of labour and expense."

If the Pine-house, *fig. 2*, were supplied with bottom-heat by tan alone, then we would wish it to be 4 feet deep, but when heated by hot-water pipes we would prefer a concrete basin beneath them, 6 inches of rubble above them, and not more than 18 inches of tan above that. We agree, then, with our correspondent, in the shallowness of the plunging material, and also in the mode of securing from the tank a moist atmosphere when desirable. We could also do the same without a tank, though not so easily. As to his other objections they are more fanciful than real. For instance: A thin layer of tan as it gets old, is as apt to be infested with worms as a deep one. Again: Persons acquainted with tan would never think of putting it new 5 feet deep in a bed at once, without previously sweating it in a heap, and then with care in plunging, there is not so much likelihood of burning the roots as there would be by a strong heat in these six pipes in the tank. The burning could in either case only take place from carelessness, but though the turn of a valve will regulate all to a nicety, that valve may not be touched, and then there is a steamer and no mistake. Neither do we agree in the impossibility of keeping a moist atmosphere in house No. 2, because it is elevated so high above the ground level. The floor in either case may be kept equally damp. If stage No. 4 is slate, a ledge might be placed all round, and water kept on it as in a shallow cistern, and the bottom of the pots, &c., could stand above the water. We see no reason why the lower pipes should not pass through an open gutter, and be more under command than when placed under a bed. And the impossibility of

getting the zinc troughs to act seems the strangest complaint of all. Because there are rims or beads encircling the pipes at certain distances, is that any reason for putting the zinc troughs on these rims, instead of having them of suitable sizes to be placed between them? If so done, and if in addition they are fixed on with some thin white lead, so as to exclude air between them and the iron pipes, we will guarantee that when the iron pipes are hot, and the zinc pipes supplied with water, they will give off abundance of vapour.

Though, therefore, we agree to a certain extent with our correspondent, yet we should require to know much more before we came to the conclusion that the builder or the gardener acted in "ignorance." It is not seldom that we have seen a house built for one purpose turned to another purpose for which it was never designed.

It is rather surprising that our clever correspondent has kept so closely to the track marked out in No. 2. In that and No. 3, the alteration, the bed is most unworkable. Our idea would simply be in such a 16-foot house, to have a 9 or 10-foot bed in the middle, 3½ feet behind for path, and the same in front; the pipes close to the ground, in front and ends four, two behind as returns, and to get moisture at command, and four in the centre beneath the bed, and 20 inches of tan above the rubble, with shelf at front and back. Above the pipes in front have a shelf of 14 or 15 inches, and several against the back wall above the height of the Pines; and with such an arrangement it would trouble us little whether the floor was raised as in No. 2, level with the ground as in No. 3, or sunk below it as many Pine-houses are.

Shading is purely a gardening matter, and needed at times in one case as much as in the other, especially if the plants are used to it. It is most required in changeable weather.—R. F.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

The late fine weather has, we trust, been taken advantage of for carrying out all operations previously directed. Perseverance must still be continued in the way of hoeing, forking, and surface-stirring amongst progressing crops, particularly Coleworts, Cabbages, late Savoys, and Curled Kale, as considerable demand for articles of this description may be expected throughout the season, and more especially in the spring. Spinach, too, must have the same attention, and the under or decayed leaves should be cleared away in due time. *Asparagus*, the haulm to be cut on a fine day when sufficiently decayed, tied in bundles, and used for thatching purposes. When clearing the refuse from *Asparagus*-beds, and the decaying leaves from the Broccoli, Kale, Savoys, &c., observe particularly if there are any fresh-used mouse-holes; if any should be discovered, get some water at once and begin pouring it hastily into the hole, which will be the cause of starting the inmates, otherwise when the Pea-sowing season arrives these vermin will eat and rout part out of the soil. It is necessary to have a flat brushy bough in the hand to destroy them. *Artichokes*, cut down any remaining flower-stalks, remove a few of the large outer leaves, and cover the roots with dry litter or old tan. *Beet*, take up the roots carefully, and having cleared them of leaves preserve them in sand in the same manner as Carrots. *Cauliflowers*, look well to these and Lettuces; take off decayed leaves, and dress with lime; give air to those in frames at every favourable opportunity. The Cabbage Lettuces intended for winter use will not need it so freely.

FLOWER GARDEN.

There should be no more delay in carrying out the necessary preparations for severe weather. The angry storms of autumn are gathering power; the limitation of solar light, the brooding mist, and above all, the fall of the leaf, are significant warnings of the approach of winter to all whose interest extends to a garden. Whenever out-door operations are interrupted, the preparation of all sorts of protective materials can be actively promoted. The stock of Russian mats should be tied, and others of reeds, straw, &c., should be made. Hardy creepers should be examined at this season, all unnecessary spray removed, and their security from the blasts of winter insured. The Dahlias to be marked or numbered forthwith, if not already done. The

beds to be now looked carefully over to see if there be any choice plants which cannot be suffered to become frosted, such to be taken up, potted, and removed to the frames. Wherever alterations are in progress lose no time in completing the transplanting of evergreens, the present mild damp weather being favourable for their removal. Such parts of the lawn as are contiguous to the mansion to be swept daily to remove leaves and worm-casts, and the gravel walks to be frequently rolled to preserve a smooth surface. The present is a good time for re-arranging the herbaceous ground; this is rendered necessary every two or three years by many of the free-growing plants growing too large. Continue to clear off decayed matter from the flower-beds, and continue the planting of Tulips, Hyacinths, Crocuses, Anemones, &c. Spring-flowering plants, such as Primroses, Cowslips, Polyanthus, Iberis, Arabis, Alyssum, Wallflowers, Canterbury Bells, Sweet Williams, Foxgloves, &c., to be planted in masses in the beds and borders, thus imparting a cheerful appearance during the winter months, and producing a gay effect in the spring.

FRUIT GARDEN.

Bush fruit may now be pruned. Let no two branches in the Black Currant and Gooseberry touch. When finally thinned these seldom require shortening. Follow with Cherries, Plums, and Apples. In pruning Apples the thinning of the branches or old wood should be the first step. Avoid cutting out large limbs, unless a severe necessity requires it. In thinning the young wood of espaliers, the principal points are to secure a continuance of leading shoots to form a compact tree and the free admission of sun and air to all parts of the tree. Towards Christmas lay by the knife until the early part of February, when the Filberts will be blossoming; then a slight thinning of the crowded and inside spray to be given to them. The Apricots will also at that time give indications by which to know the blossom-buds, when they may be pruned. The Peach and Nectarine will succeed the Apricot, and these may be followed by the Pear, and lastly by the Fig. Raspberries may now be planted and pruned. Pay every attention to getting the wood of Peaches and Apricots well ripened by exposure to sun and air. Prepare for planting all kinds of fruit trees by putting the ground in good order for the different kinds. On cold stiff soils it is advisable to plant on hillocks 1 foot or 18 inches higher than the surrounding surface. The trees will not grow so fast in consequence, and will require more attention in summer in the way of mulching; but they will form short-jointed, well-ripened, fruitful wood, which is the best preventive of canker, gum, &c., and will save the labour of resorting much to root-pruning.

GREENHOUSE AND CONSERVATORY.

Hyacinths and other Dutch bulbs, if not already bought, should be procured and potted without delay. The old *Salvia splendens* is a very gay plant, and useful for mixing among *Chrysanthemums* in the show-houses. Let Azaleas be tied into form as soon as can be done. Repot strong-growing *Pelargoniums*. There is sometimes occasion to employ fires at this period in the year, as much to promote an active ventilation and remove all superabundant moisture as to make up for the deficiency of heat from external sources. However, assistance of this kind must be used with great circumspection, and no actual interruption given to the system previously advised, of gradually reducing the temperature to correspond with the natural decline of the season and consequent limitation of solar light and heat. Considerable mischief is sure to ensue from an injudicious application of fire heat, particularly if used at night, and this should be kept in view throughout the season. This rule of treatment applies more particularly to conservatory and greenhouse stock, which it is desirable to maintain in a state more or less quiescent. A contrary system must be put in force with growing Begonias and other stove plants for early flowering. The excitement of bottom heat is of the utmost advantage, and that, of course, can be best secured to the plants by plunging them in bark or leaf-beds.

PITS AND FRAMES.

Abundance of air and light must be admitted to these structures. If any of the lights afford a partial shade to the plants, from the accumulation of dirt thereon, take them off and wash them thoroughly without delay. Be careful

during the operation of watering to apply it only to plants that require it. Remove all mouldy and decaying leaves, and keep the interior as dry as possible during dull foggy weather.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

WEATHER generally stormy and wet, and work regulated accordingly. In fine days hoed, cleaned, and stirred; in wet days made boxes, tallies, washed pots, mended and made straw covers or hurdles. Tying and roping Onions in bundles formed also part of our work. Covered a bed of Dwarf Kidney Beans with old sashes, &c., but find they do not swell so fast as we should like. With a few sunny days they would be all right, and would last some time after frost came. Trapped and caught slugs, mice, &c., and pricked out a few more Cauliflowers and Lettuces. Gathered the rest of the Capsicums, and learned from a chief of the kitchen what we surmised last week—that the seeds of the Chillies are as good for Cayenne pepper as the outside of the seed-vessel, but the colour is so wanting in red that gentlemen would not believe it to be Cayenne. We recollect something of the badinage with which a nobleman was assailed for recommending a little curry powder to the hard-working labourer before he went to bed at night, and we have no doubt it was a very good advice. A bit of Capsicum or a little Cayenne in hot water might keep off many an ailment from men who go home wet, and sit in their wet clothes.

We trust that the much that has been said for the last month on working men's homes will not end in mere benevolent talk. Cottages often, had as they are, are palaces to the accommodation which many lads put up with at farmhouses. Need we wonder that many of them become old men at thirty, when as horse-boys they frequently wear their wet clothes from one end of the week to the other, and are not permitted a fire either to dry their garments or cook their victuals? There is much need for such matters being looked into. Only lately we heard of a farm undergoing alterations and improvements, and the mechanics and labourers were denied the use of a fire and debarred the privilege of hot water. Is it natural to suppose that men would work with energy who, in addition to walking a number of miles in the morning, must carry with them their tea and coffee in a liquid state in a close vessel, and if they wished it warmed must resort to a heap of lime, intended for mortar, for the purpose? To their honour be it stated, that proprietors generally have had such matters changed when it came to their knowledge. It is owing to this knowledge, and a determination that those who work for them shall be comfortable, that gentlemen have swept away many of those filthy holes of bothies in which young gardeners were forced to reside. That there are still some remaining that, in point of comfort and healthiness, are far inferior to the pigsties and corn-byres in the home farms is almost entirely owing to want of inquiry about the subject, and to a want of the matter being courteously placed before them. Head gardeners' houses have partaken of the improvement. Nothing can be more cheering than the nice commodious homes rising in every direction; but there are many still needing great improvement and enlargement. Not long ago we saw a miserable back shed in which a large family had been reared that was scarcely large enough for a single man to live in. Gardeners who are privileged themselves with healthy homes should leave no means untried to obtain a healthy residence for the young men that live on the premises. The rain falling heavily, and the mud-covered rain-dragged state of many young labourers going home to miserable quarters, must form our apology for the above. We would also observe that all such selfishness as we have referred to will be sure to fail in its aim. To get the most from a man when energy is most needed he must be used considerably in unfavourable weather. The days of setting men to nail in keen frosty weather with the falling snow blinding them, or mowing long after the rain streaming down their backs has gurgled out of their boots and shoes, will be remembered, we trust, as belonging to a rude and barbarous period. We have seen the latter done when four-fifths of those employed, from being in lodgings, had

no chance of drying their clothes unless what could be done by the chance sun of the following day. Capsicums and even a good Onion would be no bad thing under such circumstances.

FRUIT GARDEN.

Gathered most of the Apples and Pears, except a few late ones of the latter against walls, as Easter Beurré and Beurré Rance. Forked among Strawberries as the ground was becoming hard on the surface from the rains. Pricked out runners thickly in case they should be needed. Pruned and thinned Raspberry plants, which ought to have been done earlier. Swept the leaves gently off Peaches and Apricots that the wood may be more indurated. Did the same with Figs, and will slightly protect the latter out of doors. Rough-pruned Currants and Gooseberries so as to let more light into what was left, and will do the same with Apples and Pears as soon as we can get at them. Kept a little fire in vineries to dispel damp, leaving air on as yet night and day at the back of the house; but unless in a very fine sunny day gave no front air—in fact, have given little front air all the season, and find, that as a general rule, early air-giving renders a great amount of air needless, especially when your fuel is a matter of consideration. The heat in the pipes and flues during the day in some places, would lead one to imagine that the gardener was running a race of heat against the sun, and was determined to beat him.

Our Melons are about over, as they would require more heat than we can well give them to impart flavour, and most people are afraid of such fruit so late in the season. Where Vines are started early they should have a low temperature at first—from 50° to 60°, and plenty of moisture in the air until all the buds are broken. Pines intended to show fruit from Christmas to March should now be kept moderately dry at the roots and in a drier atmosphere, but not much reduced in temperature—say from 60° to 65°. Those ripening should also be kept drier, and those swelling should have a damper atmosphere, especially in sunny days. Plants grown in dung-pits should have the linings well raised about the pits, so that heat may be thrown into the walls without moisture from the dung. The drier the atmosphere in dung-pits in winter the better, as there will be sure to be enough of moisture if dung alone is used as a heating medium. No doubt hot-water pipes are the most economical and cleanliest mode of heating, merely as regards heating, but many of us find that when we give up dung for heating, we have a difficulty of getting dung at all; and these beds and linings were grand heaps to go to for all the general crops of the garden.

ORNAMENTAL GARDENING.

Much the same as last week. Stove climbers should now be cut partly back to give more light. We must except such as *Bignonia venusta* and *Combretum purpureum* now in bloom, but all other Bignonias, Passifloras, &c., may be pretty freely dealt with. It is safest to do this work at twice and thrice, and the roots get more used to it, and are not checked so much as if it is done at once. Did the same with conservatory climbers, and will do more by the end of the month. We have, as yet, taken up no more plants from the flower garden, as it is still passable; but whenever there is a sign of frost will lift what we want, place them in sheds, and treat as we wish afterwards. Gave plenty of air to all bedding-plant cuttings. The *Calceolarias* after being inserted in a cold pit and watered, have had nothing done to them since, but air is given at night, and shut out next day at 9 A.M., if sunny, and left on if shady. Swept and rolled lawns, as worm-heaps are now becoming unsightly, and will continue until we have a frost. Dahlias still good.—R. F.

METHOD OF KILLING SLUGS.—Some time ago M. Comman-deur, of Paris, accidentally left in his garden a pot, in which he had been making experiments with starch and iodine, which pot, imperfectly covered with a piece of board, remained exposed to the heat and rain for three weeks, when on looking one morning into it, he was surprised to find it tenanted by scores of snails and slugs that had congregated in it from every part of the garden. He repeated the experiment several times, and ascertained that the emanations from iodine will attract these creatures from a considerable distance, when they may be killed by hundreds.

TRADE CATALOGUES RECEIVED.

W. H. Davis, Newbury, Berks.—*Descriptive Catalogue of Selected Roses.*

A. Verschaffelt, 50, Rue du Chaume, Ghent.—*Catalogue of New Plants.*

COVENT GARDEN MARKET.—Oct. 17.

The supply both of fruit and vegetables is amply sufficient for the demand. Late Peaches may still be obtained, and a few Melons. Of foreign Grapes there is an abundance. The Potato market is still heavy, and some diseased samples are making their appearance. Cut flowers mainly consist of Orchids, Roses, Pelargoniums, Asters, Marigolds, Violets, Mignonette, and Wallflowers.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

JELLY-LIKE SUBSTANCE (*H. A. D.*).—It had become entirely liquid, but we have little doubt that it is Tremella nostoc, a cryptogamic plant in the form of jelly-like lumps, and frequently found on gravel walks. It is sometimes called Star-slug, it being popularly considered as an emanation from the stars.

TURNING OUT VINES (*J. T. Swansea*).—We would advise you not to turn out your Vines at any season. Turning out Vines is only necessary and advisable when the vineyard has to be turned to some account during the season the Vines are at rest—such as for forcing anything else requiring a temperature too high for Vines. If this be desired in your case, the Vines may be turned out; but it is not good to expose them unprotected to more than 6° of frost, and some covering of mats or straw should be put over them to protect them from severe weather. The best management for Vines from which the fruit is all cut early in October, is to keep them as cool and airy as possible all the winter. The temperature should not exceed 40°. In the case of Vines that have not well ripened their wood a little more heat and a circulation of warm dry air should be applied immediately the fruit is cut, and continued till the young wood becomes quite brown and firm. As soon as all the leaves are shed they should be pruned. All other particulars you will learn from the treatise sent according to your wish. Sanders "On the Vine," is published at our office. If you send sixty-two postage stamps with your address you can have it free by post.

GRADE VINES WEAR (*An Old Subscriber*).—To make your Vines stronger you might give a hundredweight of superphosphate of lime to the eight-foot border. This, however, would not prevent shanking. If you have given air enough the cause of the shanking is deep roots or undrained roots—that is to say, unless you have too heavy a crop. If from stagnant water, a deep drain in front of your flower-border would do much, as most likely the roots are already beneath the flower-beds. We should be inclined to try that and the enriching the eight-foot border for this year, making the superphosphate go all over in three or so, a month apart, choosing dry weather and watering directly. To make perfectly sure against shanking, if from stagnant moisture and deep roots, lifting would be the great remedy; and in your case if you lifted we would advise planting inside, taking the roots outside as well through openings in the wall, and confining them outside to the eight-foot space. We would secure drainage at the same time, and use fresh soil, especially in part. See account of Keele Hall as to future management.

LINUM FLAVUM CUTTINGS (*M. A.*).—You had better keep the cuttings under the glass during the winter, taking it off in mild periods, but replacing it over them in severe and very wet weather. This will protect them a little, for the plant is only hardy in some situations. Plant them out in the beginning of April, moving each with a good ball.

ASPHALT WALKS (*Aster*).—Asphalt, Bitumen, or Jew's Pitch, is found floating on the Dead Sea and elsewhere. It becomes very hard by exposure to the air, and its name has been appropriated to various artificial preparations, all of which owe their properties to the boiled gas-tar which enters into their composition. Thus the asphalt felt is rendered waterproof for shed-roofing, &c., by being soaked in that tar; and asphalt walks are most dry and excellent when made as follows:—Take two parts of very dry lime-rubbish, and one part coal-ashes, also very dry, and both sifted fine. In a dry place on a dry day mix them, and leave a hole in the middle of the heap as bricklayers do when making mortar. Into this pour boiling-hot coal-tar; mix, and when as stiff as mortar, put it 3 inches thick where the walk is to be. The ground should be dry and beaten smooth. Sprinkle over it coarse sand; when cold pass a light roller over it, and in a few days the walk will be solid and waterproof. Your bark-bed must be 4 feet deep; but will be an uncertain source of heat unless enclosed and capable of being partially stirred and mixed in the event of the heat declining. The price of the "Cottage Gardeners' Dictionary" is 8s.

STONE PEACH (*E. S., Hampstead*).—We never heard of this Florentine Peach "something between a Peach and an Apricot, both in taste and appearance." Probably it is one of those yellow-fleshed Peaches common in the south of Europe. You may sow the stones now and put the pots in your greenhouse. The plants will appear next spring; but they will not be exactly like their parent, probably in any respect. To obtain the exact variety you must procure some buds.

VINES FOR A COLD VINERY (*Lez*).—As you only look to the profit of their culture, there are no better Vines for your purpose than the Black Hamburgh and Black Champion.

CALCEOLARIAS AFTER FLOWERING (*J. F. H.*).—Take the plants up with a moderate-sized ball, and place in pots very little larger than the ball, just sufficient to contain the roots without thrusting them in. Leave all the top on the plant for about a fortnight, when all the old wood may be removed, being careful to retain the young wood. They will do very well in the pit, but you must give no more fire heat than enough to dry up damp and exclude frost. Such plants afford numerous cuttings in early spring, which strike readily in a little bottom heat, whilst the plants themselves bloom finely in May in the greenhouse, or in April if few cuttings are taken. When spring-struck cuttings are rooted and hardened-off they may be planted in nursery-beds in some sheltered situation, adding some leaf mould to the ordinary soil, putting in the cuttings 6 inches apart each way, and pressing the soil firmly round them. Water copiously, shade from sun, and protect at night from frost with mats. Such cuttings make nice bushy plants by the beginning of June, when they may be transferred to the beds, taking them up with a ball. They grow more freely than plants that have had their roots cramped in small pots during the winter.

YOUNG PEACH TREES UNFRUITFUL (*J. F. H.*).—Try what less pruning will do towards rendering your trees more fruitful. If the trees are very vigorous cut the leading shoots back but one-fourth their length, and the bearing shoots to 9 inches, and leave them that distance between each. If the wood ripens well and gross growths are not made late, we do not see what is to hinder them fruiting another year. However, should they make rampant growths which do not ripen, and are not well studded with bloom-buds, take them up, plant on the surface, and cover the roots with 3 or 4 inches of soil; tread it firm if light, and mulch the surface where the roots are to preserve them from frost and the drought and heat of summer. If the border is rich and deep it should be made shallower, 20 inches of tenacious loam on a concreted bottom with perfect drainage being the essential elements of a Peach-border. If your border is all right and the roots not deep, be content with a few fruit, as your trees will be all the better and the crops much finer in future years than when they are allowed to bear heavy crops before the tree is half formed. For propagation directions buy our "Garden Manual," which you can have free by post for twenty postage stamps from the office of this Journal.

ROOT-PRUNING OLD FRUIT TREES (*A Novice*).—Root-pruning will only be beneficial to trees which are over-luxuriant, and that is not likely to be the state of your old fruit trees. They probably are weakly and moss-covered. If so, paint them over with a creamy mixture of quicklime, manure the soil, and keep it mulched throughout the dry weather in summer.

QUANTITY OF TOBACCO REQUIRED FOR FUMIGATING (*R. T. B.*).—Two ounces of shag, if the pit 12 feet by 8, is 2 feet in depth, and four ounces if it is double that depth. The smoke to remain until it vanishes. It will do so in about an hour; but sooner in a dry than damp atmosphere. The plants must be dry when smoked.

PROPAGATING CENTAUREA CANDRISIMA AND C. ARGENTEA (*R. T. B.*).—To obtain a stock keep the plants in a dry airy place until spring, when cuttings may be taken when the plants have young shoots about 2 inches long. They strike freely in silver sand if placed in a little bottom heat. Seeds sown in spring make good plants by that time twelve months.

MIGNONETTE FOR CONSERVATORY (*J. J. J.*).—It is too late now to sow seed for the decoration of the conservatory in winter and spring. However, if you have any plants in the garden, nice bushy young plants that have not flowered, take them up with good balls and pot them in 24-sized pots in a compost of light turfy loam and leaf mould with a free admixture of silver sand. Water sparingly and keep in the shade for a few days; then pinch off the flowers. Give just enough water to keep them growing during the winter, and place them near the glass in a well-ventilated part of the greenhouse or conservatory. Such plants bloom freely throughout the winter and spring, but are not so fine as plants raised and grown for the purpose. We will be in time with an article telling you how to obtain fine plants for another winter. *Santivitalia procumbens* is worth little as an edging. It would not last through the summer in good condition.

MIRTLE LEAVES DISEASED (*A Subscriber, Manchester*).—They are very severely infested by the scale insect. Wash the leaves and all the branches with a creamy mixture of soft soap, flowers of sulphur, and tobacco water. Boil half a pound of tobacco in two gallons of water, dissolve in it 1 lb. of soft soap, with which 1 lb. of flowers of sulphur has been made into a paste. Leave the plant for two days after being thus washed, and then wash it in water at the temperature of 120°. Give your plants more and moister air.

SIX DARK HYBRID PERPETUAL ROSES (*Inquirer's name lost*).—Empereur de Maroc, Engée Appert, Alexandre Dumas, Cardinal Patrizzi, Madame William Paul, and Princess Mathilde.

WALNUT TREE NOT BEARING (Lez).—You will find an article in another page replying to the inquiries you have made.

HEATING A SMALL GREENHOUSE (Gylling).—We do not know what piping you have, and, therefore, cannot say whether you will have sufficient. With an iron plate or two you could bank the fuel at bedtime against the reservoir at the back of the parlour fire. You might also secure a good amount of heat from a good gas-burner placed beneath a concave vessel, and a pipe from it going out of doors to carry away the fumes. Perhaps a small stove with a small iron chimney through the roof would be the simplest. We object to any stoves inside that have no outlet for the products of the combustion.

HEATING A PIT (A Subscriber).—We can hardly understand how you have used your iron vessel $3\frac{1}{2}$ feet long, 2 feet wide, and 9 inches deep. If set upon a hot fire, and 6 inches of sand placed on the bottom of it, you would have heat enough if you covered the top with movable glass. You do not tell us when you tried your cuttings. Verbenas need no extra heat in autumn. The idea of taking a flue round such a trough and setting it in a two-light frame seems to be doing much work for little use. If you have no regular heat in your flue, the best way to use such a tank for propagating in a cool greenhouse, would be to elevate it either on the flue or otherwise. Drill a hole at bottom for sap or plug, to empty it when desirable. Leave space for 3 inches of water at bottom. Support in that this slate, covered with 2 or 3 inches of sand, have a pipe and funnel put in hot water, and draw off when cold—say once a-day. Wrap the tank round with cocoa-nut matting or cloth of any kind of wood. For small propagating-houses, see no end of descriptions, and watch for a notice of Mr. Lane's propagating-houses. We could say nothing as to your tank standing fire heat unless we saw it.

VERBENA AND PETUNIA CUTTINGS (Anna Ardagh).—As they are well rooted you may top them now being too much drawn. Give them more air and light.

POETRY (G. D.).—The verses would do very well for a lady's song, but they are not suitable for our Journal. Very few people are aware that rhyme is not necessarily poetry.

JOSÉPHINE DE MALINES PEAR (F. Hawes).—The following is the description given in Dr. Hogg's "Fruit Manual":—"Fruit about medium size. Skin yellow with a greenish tinge on the shaded side, and with a tinge of red on the side next the sun; the whole surface strewed with large russet spots. Eye open, set in a rather shallow depression. Stalk three quarters of an inch long, stout, and inserted in a narrow cavity. Flesh yellowish, with a tinge of red, melting, and very juicy, sugary, vinous, and richly flavoured, with a high rosewater aroma. A most delicious Pear, in use from February till May. The tree is hardy, and an excellent bearer." No better aspect than a south wall could be had for Green Gages.

INSECTS (J. E. B.).—The caterpillar you have sent, found devastating a Rose tree, is that of one of the moths forming the family Geometridæ, and appears identical with *Geometra plummaria*, Hb. Should you find any other specimens we shall be obliged by your sending them to us, but we believe its connection with your Rose tree was accidental.—W.

VARIOUS (H.).—We have no faith in sawdust for mulching, and do not like it at all unless charred or thoroughly rotten. We should employ the peat earth or heath soil as described. Pulverised freestone clippings will answer as well as silver sand for the purposes to which it is applied if the freestone is free from chalk, and still more, is not impregnated with magnesian limestone. In these cases it will not take the place of silver sand. The phosphatic green sand we fear would be more fit for manure than for striking cuttings. Sea sand would not answer for propagating purposes unless thoroughly washed, neither would pounded chalk or marlstone by themselves or mixed with such sand. Such sand in heavy land would be a good dressing for Sea-kale, Asparagus, &c., and a sprinkling of it would do good to most kitchen gardens. The Vines are planted, and the stems trained either over a trench, or some 9 inches above the ground, the ground being covered with slate and a hipped roof of small dimensions—say 18 or 24 inches wide, and 15 to 18 inches on the side of span, and if moveable, lengths of 6 feet or so are placed over them, set upon bricks every 2 feet or so, which admit enough of air between them in the hottest days. We do not know your place of residence; but we have more faith in your succeeding by this mode than by planting Vines in the open ground and training them to rods, as done in France and on the Rhine, much as we do Raspberries here. It is just possible that in a warm sheltered spot you would succeed. Mr. Rivers used to succeed pretty well with these ground vineries, of which you will find a drawing and description in No. 28, page 30. The slates, whether on the level or as forming the sides of the trench, were covered with sulphurous paint.

FLIES ATTACKING GRAPES (J. Forrest).—Prevention is your only remedy. Keep the flies out of the vine by putting lace-net over the windows and ventilators.

ALOCASIA LOW CULTURE (George Sim).—If it be well established in the pot, and the roots matting round the pot, give it a shift into a pot 3 inches wider than the one it is now growing in. Drain well, and pot with a compost of turfy peat and fibry loam three-fourths, equal parts of both, pieces of charcoal the size of a hazel nut, and silver sand the remainder of a whole. It, like its congener *Alocasia metallica*, requires a high stove temperature and abundance of atmospheric moisture. A temperature of 65°, is not lower than 60° by night, in winter, with a rise of 10° or 15° by day, is about the proper winter temperature, during which it should be kept moderately dry at the root. It will need shifting again as growth commences in spring, a more frequent application of water, and an increase of temperature; 70° by night is not too high, whilst in summer it will not harm this plant if the temperature range to 75° by night, with an increase of 10° in cloudy weather, and from 15° to 25° with sun by day. It should be kept near the glass, or it is apt to become drawn, and must have abundant atmospheric moisture and water at the root when growing.

ANOMATHECA CRUENTA SEED SOWING (M. D.).—Sow in spring in a gentle heat. Keep there until the plants appear, then gradually harden-off and grow on in the greenhouse. Another way is to sow the seed outside, and thus save the trouble of raising in heat. The former plan, however, makes a plant in half the time of the latter. It is quite hardy, as you no doubt know, and we can say with you, "It is a great favourite here," and only needs seeing, though it is as old as the hills, to win a place in every garden.

PEACHES FOR WALL IN THE NORTH OF IRELAND (Belfast).—You will find Early York, Barrington, Bellegarde, and Noblesse, do very well with you.

FERNS INFESTED WITH THAIRPS (Idem).—You cannot smoke too soon; but do it gently, yet filling the house with smoke. Do this two nights in succession, syriaging the plants the morning after each smoking; but you must have the foliage dry before smoking, though you may and ought to sprinkle every available surface with tepid water twice daily, taking care not to wet the fronds. This will surcharge the atmosphere with humidity or moisture, and that is what Ferns require. You must not expect the first nor even the second smoking to thoroughly eradicate the thrips; though it will destroy all the perfect insects, yet there are eggs which will hatch in a few days: therefore the moment you see thrips smoke at night, and continue to do this until a thrips cannot be found. Our "Fern Manual" would save you much of the trouble you complain of.

GNAPHALUM LANATUM PROPAGATING (M. D.).—Cuttings of the young shoots strike readily in loam, leaf mould, and silver sand in equal parts, placing them in a bottom heat of 75°. They also strike freely in a greenhouse with a bell-glass over them, but are longer about it. Cuttings are best put in in August, which are potted-off when struck, wintered along with the other bedding plants, and every way having the treatment of a Verbena. It is rather impatient of damp, but not more so than Verbenas. If the plants are placed in a warm greenhouse, say 50° by night, in the beginning of February, they will grow freely and each give many cuttings in March; and if they be taken off with four joints, cut immediately below the lowest leaf transversely, the two lowest leaves removed, and inserted round pots in silver sand with a little loam and leaf mould in it, gently watered through a fine rose, and then plunged in a brisk bottom heat of 75° to 80°, the cuttings will root in a few days. Then they must be hardened-off gradually, potted into 48-sized pots in a compost of loam and leaf mould in equal parts, with a little silver sand intermixed. Such make first-class edging plants, second to no silver-edging plant in cultivation.

SALVIA PATULA NOT FLOWERING (M. D.).—It is a biennial from Portugal, and is hardy in most localities. You have coddled it, and nearly killed it with kindness. Plant it in the garden border next summer in the full sun, and give it some nice soil as a little leaf mould, but not strong manure, and thus induce free growth. Its existence is only prolonged by striking it from cuttings, and as in the case of many other biennials and even annuals, it is weakened by the process, and they could be had stronger and freer-flowering from seed. Cultivators will find nature's laws cannot be long broken with impunity, of which your plant affords an example. If you succeed in obtaining seed sow the spring following in the open garden, unless you live in an exposed situation, when the plant had best be treated as a half-hardy annual, only that it lives over the winter and flowers the second year. Like *Salvia* in general it requires a light sandy, loamy soil, and when grown in-doors, an abundance of light and air.

ANEMONE VITIFOLIA VAR. HONORINE JOBERT.—Messrs. E. G. Henderson and Son inform us that the Floral Committee awarded them the prize for this flower, and not to Messrs. Smith. We received our list from the Floral Committee.

NAMES OF FRUIT (Rev. Dr. Binney).—1, Marie Louise; 2, Beurré d'Aremberg; 3, Beurré Diel; 4, Winter Nelis; 5, Beauty of Kent; 6, Passe Colmar; 7, Gansel's Bergamot, this is evidently from a standard; 8, 9, and 10, unknown. (E. Meachen).—No. 1, quite rotten, appears to be a very worthless variety, which should be regraded; 2, Louise Bonne of Jersey.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (E. M.).—Your large plant is commonly called Ground Ivy, also Gill, Ale-hoof, Turn-hoof, and Cat's-foot. Its botanical name by most authors is *Glechoma hederacea*; but Bentham calls it *Nepeta Glechoma*. The other little plant is commonly called the Ivy-leaved Toadflax, or Oxford-weed, and botanically *Lianaria cymbalaria*. (Subscriber since 1856).—*Hippastrum equestre*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY EXHIBITIONS.

WHEN this is in our readers' hands the Crystal Palace Show will be in progress. We hope no amateur will miss the opportunity of seeing it. It is the place of places for a pleasure show, and we are glad to see exhibitors are alive to its merits. The competing pens are 1002, an excess of 230 over last year. Our report next week will, we hope, treat of the successes and congratulations. We can but think the alteration in time that has done away with the clashing of this Show with the respected mother of all Shows at Birmingham was a very wise one, and we hope it will be for their mutual benefit.

We receive many communications from friends lamenting the lack of shows in the south and south-west of England.

"'Tis true, 'tis pity; 'tis pity 'tis 'tis true;"

but we cannot help it. Exhibitors must go farther from home in search of foemen worthy of their steel, and with all the facilities of the present day, Birmingham is nearer to London now than Reigate was a few years since. We advise our friends to enter at Birmingham, and we warn them the entries close on the 30th of this month.

It is well worth while to try conclusions at that great Show. There are giants there if you are greedy of honour; and buyers are thick as leaves in Vallambrosa if you wish to dispose of your extra stock. A triumph there gives distinction to a yard, and it is a great satisfaction to find victories at smaller shows repeated here on a larger scale;

or if defeated, you gain that knowledge by comparison which will make success easier, if not certain, thereafter.

Our correspondence goes far to prove to us that the number of exhibitors increases, but with many there is a shyness to encounter large shows, while they are almost careless of success at smaller ones. There is no real foundation for this. The pen of Dorkings, Hamburgs, or Game, as the case may be, which has been successful over three or four others at the local or agricultural show, may possess every qualification for the silver cup at Bingley Hall. Neither should exhibitors be deterred from showing because there is a defect in one of the three birds forming the pen.

We endeavoured last week to give a scale of defects in some breeds, marking those that were disqualifications, and those that were not. Much of the importance to be attached to such a division springs from the fact that there will not probably be, among the two thousand pens of poultry shown at the Crystal Palace and Bingley Hall, one so perfect that it could challenge the Judges to find a defect or to suggest an improvement.

Some shows sell half the birds sent to them, others very few. Among the former, the Crystal Palace and Bingley Hall are pre-eminent. The Palace sells some hundreds of pounds worth; Bingley Hall makes sure of selling between seven and eight hundred pounds worth; and these sums are scattered broadcast among poultry amateurs. This is by far the most profitable manner of disposing of extra stock. We do not for a moment mean to say there is a sale for bad birds, or that it is a place to get rid of decidedly inferior ones, but average fowls in good condition put in at moderate prices meet a ready sale. Sometimes pens sent for this purpose find themselves first-prizetakers, and we shall be indeed glad if such should happen to any of our readers who may be induced to send by what we have written.

CRYSTAL PALACE POULTRY SHOW.

This Show commenced on the 19th and will continue till the 22nd. Beneath we give a list of the prizetakers in the various classes, and will give in our next issue the names of the owners of commended pens, as well as a detailed report.

SPANISH CHICKENS (Cockerel and two Pullets).—First, D. Parsley. Second, J. Biggar. Third, E. T. Holder.

SPANISH (Cockerel and one Pullet).—First, D. Parsley. Second, H. C. Mobbs.

SPANISH COCKS.—First and Second, D. Parsley. Third, C. Cayford.

DORKINGS (Coloured, Cockerel and two Pullets).—First, H. R. Seymour. Second, Capt. W. W. Hornby. Third, Viscountess Holmesdale. Fourth, Mrs. F. Blair.

DORKING (two Pullets).—First, W. Dolby. Second, Mrs. F. Blair.

DORKING (White, Cockerel and two Pullets).—First, Rev. G. F. Hodson. Second, Lady Mary Legge.

DORKING COCKS (Coloured and White).—First, C. Priest. Second, Miss Wilcox. Third, Mrs. F. Blair.

COCHIN-CHINA (Cinnamon and Buff, Cockerel and two Pullets).—First, Viscountess Holmesdale. Second, T. Roucher. Third, C. T. Bishop.

COCHIN-CHINA (Brown and Partridge).—First, T. Stutch. Second, Rev. G. F. Hodson. Third, R. Adams.

COCHIN-CHINA (White).—First, Viscountess Holmesdale. Second, G. Chase. **COCK** (Coloured and White).—First, J. Wright. Second, C. H. Wakefield.

BRAHMA POOTRA.—First, W. L. Barclay. Second, Mrs. Blair. **COCK**.—First and Second, C. Priest.

GAME (White and Pies).—First, W. Burgess. Second, Miss Crawford. Third, A. Ewen.

GAME (Black-breasted Reds).—First, J. Stubbs. Second, Rev. G. S. Cruwys. Third, S. Matthew.

GAME (Brown-breasted and other Reds, except Black-breasted).—First, J. Wood. Second, T. Moss. Third, A. B. Dyas.

GAME (Duckwing and other Greys and Blues).—First, W. Pares. Second, W. T. Everard. Third, T. Dyson.

GAME (Any variety).—First, W. Dawson. Second, J. Fletcher.

GAME COCKS.—First, J. Stubbs. Second, S. Matthew. Third, J. Cook.

HAMBURGS (Golden-pencilled).—First, N. Barter. Second, W. H. Dyson. Third, Captain Pares.

HAMBURGS (Silver-pencilled).—First and Third, Viscountess Holmesdale. Second, J. Robinson. **COCK** (Gold or Silver-pencilled).—First, Capt. Pares. Second, H. Beldon.

HAMBURGS (Golden-spangled).—First, J. Ellis. Second and Third, G. Brook. (A remarkable class.)

HAMBURGS (Silver-spangled).—First, E. Collinge. Second, T. Craveo. Third, J. Fielding. **COCK** (Gold or Silver-spangled).—First, H. Beldon. Second, J. Dixon.

POLANDS (Black, with White Crests).—First, J. Smith. Second, H. Carter. **POLANDS** (Gold).—Prize, J. Dixon.

POLANDS (Silver).—First and Second, G. C. Adkins.

POLAND COCKS.—First, J. P. Edwards. Second, J. Dixon.

MALAYS.—First and Second, N. Sykes, jun.

ANY OTHER DISTINCT BREED.—First, J. Hope (Black Hamburgs). Second, Mrs. F. Blair (La Flèche). Third, C. H. Wakefield (Crève Cœur). Fourth, the Countess de Flahault (Chamois Polands).

BANTAMS (Gold-laced).—First, T. H. D. Bayley. Second, M. Leno, jun. **BANTAMS** (Silver-laced).—First, Rev. G. S. Cruwys. Second, M. Leno, jun. **BANTAMS** (White, Clean Legs).—First, Miss C. H. Balfance. Second, T. H. D. Bayley.

BANTAMS (Black, Clean Legs).—First, H. Beldon. Second, R. Brotherton, jun.

GAME BANTAMS (Black or Brown-breasted Reds).—First and Second, J. Muir. Third, Mrs. Crawford.

BANTAMS (Duckwings, or any other variety of Bantams).—First, Mrs. Crawford. Second, E. Kerriell. Third, W. S. Forrest.

BANTAM COCKS (Any variety).—First, G. Briddon. Second, J. W. Kelleway. **DUCKS** (Aylesbury).—First, J. K. Fowler. Second, Sir St. G. Gore, Bart.

DUCKS (Rouen).—First, Sir St. G. Gore, Bart. Second, J. K. Fowler. **DUCKS** (Black).—First, Mrs. Wolferstone. Second, Master C. A. Balfance.

DUCKS (Any other variety).—First, A. S. Yates. Second, Mrs. C. Baker. **GEES** (White).—First and Second, J. K. Fowler.

GEES (Grey and Mottled).—First, W. Dolby. Second, Mrs. Seamona. **TURKEYS**.—First, W. Wright. Second, Rev. T. L. Fellows.

ORNAMENTAL WATERFOWL.—First and Second, C. Baker. Third, Mrs. Baker.

PHEASANTS (Gold and Silver).—First, A. S. Yates. Second, Master R. C. Welch.

PHEASANTS (Any other variety).—First, M. Leno, jun. Second, C. Baker.

PIGEONS.

POWERS OR CROPPERS (Cocks, any Colour).—First and Third, W. A. Baeuch. Second, R. Fulton. (Exceedingly good class.) **HENS**.—First, R. Fulton. Second, W. A. Baeuch. Third, F. G. Stevens.

CARRIERS (Cocks, Black and Dun).—First and Second, J. C. Ord. Third, F. G. Stevens. **HENS**.—First, E. L. Corker. Second, F. E. Else. Third, Withheld. (Cocks, any other Colour).—First, F. E. Else. Second, E. L. Corker. **HENS**.—First, Withheld. Second, F. E. Else.

DEACONS (Blue).—Prize, F. E. Else. *Any other Colour*.—Prize, — Esquilant.

ALMOND TUMBLERS.—First, E. L. Corker. Second, — Esquilant. Third, F. E. Else.

SHORT-FACED MOTTLES.—First, E. L. Corker. Second, C. J. W. Rudd. **SHORT-FACED BALDEHEADS**.—First, W. W. Woodhouse. Second, — Esquilant.

SHORT-FACED BEARDS.—First, J. Percivall. Second, J. W. Edge. **SHORT-FACED TUMBLERS** (Self-colour).—First, Mrs. Oates. Second, H. Morris.

KITES, AGATES, DUNS, AND GRIZZLES.—Prize, F. E. Else. **JACOBINS**.—First and Second, H. Morris.

OWLS (Blue or Silver).—Prize, F. E. Else. *Yellow or any other Colour*.—Prize, F. E. Else.

NUNS.—First, F. Else. Second, H. Beldon. **TURBITS**.—First, J. W. Edge. Second, F. E. Else. Third, J. Owens.

FANTAILS (White).—Prize, R. F. Jarvis. *Blue*.—Prize, J. W. Edge. **BARBS** (Black).—Prize, F. G. Stevens. *Yellow or any other colour*.—Prize, F. G. Stevens.

MAGPIES.—First and Second, F. E. Else. Third, F. G. Stevens. **TRUMPETERS** (Black Mottled).—Prize, F. E. Else. *White or any other Colour*.—Prize, F. E. Else.

RUNTS (Spanish and Leghorn).—First, T. D. Green. Second, F. G. Stevens.

ANY NEW AND DESEERVING VARIETY NOT BEFORE MENTIONED.—First, Rev. C. Spencer. Second, H. Yardley. Third and Fourth, J. Owens.

RABBITS.

LONGEST EARS.—First, W. Griffin. Second, J. Cranch.

BLACK AND WHITE.—First, C. Burge. Second, J. Morris, jun.

YELLOW AND WHITE.—First, Messrs. Hall & Co. Second, T. Soles.

TORTOISE-SHELL.—First, G. F. Grensill. Second, Miss Hawksley.

BLUE AND WHITE.—First, C. Sellen. Second, C. South, jun.

GREY AND WHITE.—First, H. Handford. Second, J. Hales.

SELF COLOUR.—First, G. Booth. Second, G. Jones.

FOR WEIGHT.—First, J. Wainer. Second, Messrs. Hall & Co.

FOREIGN.—First, J. Langham. Second, G. Buchanan.

JUDGES.—*Poultry*: Mr. J. Baily, Mount Street, London, and Mr. E. Hewitt, Sparkbrook, near Birmingham. *Pigeons*: Mr. S. J. Cottle and Mr. F. Bellamy. *Rabbits*: Mr. A. Bancks, Mr. T. H. Fox, and Mr. S. Webster.

EAST HANTS POULTRY SHOW.

The Show was an uncommonly good one of its class. There were about a hundred entries; but owing to the unfavourable state of the weather on both days it was rather poorly attended.

In *Spanish* the first and second prizes went to two very good pens of young birds, the highly commended pen being pretty fair. In *Dorkings* the first prize went to a pen of Whites, young birds of Antfill's old strain, and which were extremely fine. The second prize was awarded to a magnificent pen of Greys belonging to Mrs. Rothery. In the *Cochins* there were some good birds; but the noted Mr. Kellaway's birds eclipsed everything. They were in capital condition for the time of year, but hardly over their moult. The commended pen was not over-good. The *Game* birds were exceedingly good. The names of the exhibitors speak for themselves; but the first prize was withheld, as they were not sufficiently good to merit it. The *Hamburgs* were very poorly shown, there being only two entries, both of chickens, but exceedingly good. The *Polish* were also poorly shown. Mr. T. P. Edwards was the only exhibitor. The

Any other variety class was well represented by two splendid pens of Brahmas, to which first and second were awarded. Mr. C. Coles sent some very fine Andalusian chickens, but they were too late for competition. Some very good *Bantams* were shown, the Black Red Game of Mr. Kellaway taking first prize, and the cup for the best pen in the Show. The cock is a perfect Game in miniature in every respect, and does the owner credit. Mr. Nicholson's Duckwings were very good, the cock (an old bird) having a splendid wing, in fact, a perfect Game Duckwing. Mr. Sandford showed a good pen of Brown Reds, but they arrived too late. The Single Cock class was the best in the Show. The first-prize birds were splendid. It was the same as that which took first at Islington this year. The second was also a beautiful bird. The third was likewise good. Had not the Game been so good the prizes would have been richly deserved by Mr. Edwards for Polish, and Mr. Priest for his Dorking cock, both of which were above the ordinary class.

All the *Ducks* were very fine; and the *Geese* were above the ordinary standard. The *Pheasants* were well represented by three good pens; and the Ornamental Waterfowl consisted of a good pen of White Call Ducks.

The *Pigeons* to which the prizes were awarded were good, but the rest were very inferior. The *Rabbits* were good.

SPANISH.—First and Second, Rev. T. R. Browning, Southsea. Highly Commended, J. Eyles, Southsea.

DORKINGS.—First, H. M. Ford, Portsmouth. Second, Mrs. Rothery, Haslemere, Surrey.

COCHIN-CHINA.—Prize, J. W. Kellaway, Isle of Wight. Highly Commended, J. K. Fowler, Aylesbury.

GAME.—Second, M. Billing, Jun., Gravelley Hill, Birmingham. First withheld. Highly Commended, H. Adney, Lymington, Devon.

HAMBURGERS.—First and Second, G. W. Ranwell, Portsea.

POLISH.—Prize, T. P. Edwards, Lyndhurst, Hants. Highly Commended, T. P. Edwards.

ANY OTHER VARIETY.—First and Second, C. Priest, Worthing.

BANTAMS.—First and Cup, J. W. Kellaway, Isle of Wight. Second, O. Nicholson, Fareham. Highly Commended, A. S. Yates, Alresford, Hants; J. K. Fowler, Aylesbury; M. Billing, Jun., Gravelley Hill, Birmingham.

SINGLE COCKS.—First and Cup, G. W. Ranwell, Portsea (Black Red Game). Second, M. Billing, Jun., Gravelley Hill, Birmingham (Black Red Game). Third, W. P. V. Wallis, Portsmouth (Brown-breasted Red Game). Highly Commended, T. P. Edwards, Lyndhurst, Hants (White-crested Black Poland); C. Priest, Worthing (Coloured Dorking); Rev. J. de la S. Simmonds, Winchester (Spanish); H. Adney, Lymington, Devon (Game).

DUCKS (Aylesbury).—First and Second, Mrs. M. Seasmores, Hartwell, Aylesbury. Highly Commended, W. Wildey, Cosham, Hants.

DUCKS (Any other variety).—First, J. Adams, Fareham. Second, C. Priest, Worthing. Highly Commended, Rev. D. Binney, Southampton; E. Pigeon, Lymington, Exeter.

GESE.—Prize, J. K. Fowler, Aylesbury.

GOLD AND SILVER PHEASANTS, ORNAMENTAL WATERFOWL, &c.—First, —Boad, Bishop's Waltham. Second, A. S. Yates, Alresford, Hants. Highly Commended, W. Clark, Bishop's Waltham; A. S. Yates.

FOWLS.—First, H. Bunce, Camberwell (Short-face Black Mottles). Second, A. S. Yates, Alresford, Hants (Dun Carriers). Third, R. Sutton, Deptford (Blue Pied Powters). Highly Commended, E. Pigeon, Lymington, Exeter (Runts); E. Body, Portsmouth (Red Pied Powters).

RABBITS.—First, G. Jones, Birmingham (Fawn Doe). Second, J. Haile, Millbank (Grey and White Doe). Highly Commended, G. Jones (Fawn Doe); J. Haile (Black and White Doe, Tortoiseshell Doe).

JUDGES.—*Poultry.*—Messrs. R. and J. Smith, of Portsea. *Pigeons.*—Mr. Newman. *Rabbits.*—Mr. R. Smith.

SMALL BIRDS AND THE POULTRY-KEEPER.

I AM very glad some one has taken up the subject of small birds on behalf of poultry-keepers; for I am convinced from my own knowledge and observation that where one keeps poultry he may catch his own caterpillars and grubs himself, the birds—I allude to the sparrows—never touching either caterpillar or grub while they can pick up corn, meal, &c. Having been considerably annoyed and plundered by these

little pilferers, which fly completely through the wires of my fowl establishment, I have manufactured the foregoing preventive, a sketch of which I enclose, as it may be of as much use to some of your correspondents as it has been to me.

Four posts, or as many as may be required, are firmly fixed in the ground. A coil of sparrow-proof wire is then wound all round, except at one end, outside these, and pegged down to the ground. A piece of wire is then placed over the top, and connected with the sides and end by twisting. The door is composed of the same wire fastened on a strong piece of wire bent into a square form, and of such a size that it shall swing easily in the aperture left for it. Two pieces of wire bent into an S are hooked to the top, and these hang on a piece of strong wire stretched tightly (for it must not bend) across the doorposts. The fowls push open the swing door to feed, and this sparrows have not strength to do; and the desideratum of feeding one's fowls and not the sparrows is also accomplished. After a little practice the fowls become used to it, but it must be left open at first to encourage them. It is quite amusing to watch the sparrows during this feeding; they perch round and on the wire, apparently loudly exclaiming against the contrivance and their swindle, and they adjourn afterwards in despair to the breakfast Nature has provided them with, and which, when corn-fed, they are too lazy to seek.—LEX.

RANDOM APIARIAN NOTES.

"B. & W."—I hail with pleasure the re-appearance of your excellent correspondent under this title, and should like him to give an account of the native bees of Australia. Having a near neighbour who has resided at Adelaide for thirty years and upwards, he informs me that the only drawback to the English bees which have been introduced there is, that the bees are tormented constantly by the ants, which are more numerous and of a larger size than those in England.

THE HAMPSHIRE BEE-KEEPER.—This gentleman is quite correct in describing the admirable bee season of 1857. It was one of a famous cycle of good years (also 1858 and 1859) which preceded the three untoward seasons of 1860, 1861, and 1862; and even amongst the mountains in North Wales, bees collected sufficient honey to maintain themselves during their long winters, after the three magnificent summers of 1857, 1858, and 1859.

PARTHENOGENESIS.—The Editors (the "head hitters," as the countryman called them), of THE JOURNAL OF HORTICULTURE, have given a very proper hint in a late Number to the writers, to be very chary of their remarks on this mysterious subject, not at all fitted for discussion, and I fully intend to reserve my opinion altogether.

TWO QUEENS AT A TIME IN HIVES.—Mr. Lowe seems to coincide with me, that at certain seasons an old and young queen may frequently be seen in one hive during the whole of the swarming season. I myself have frequently seen two queens, and once three, on the outside of nearly half a peck of bees which had lain out in most unsettled weather in June, when swarming had been retarded.

MR. WOODBURY.—I am glad that Mr. Woodbury parted with the extra queen mentioned, as her death would certainly have followed soon. At the same time, although his case seems an exceptional one, I am of opinion where large hives are separated by "supers" or other divisions, like Nutt's old boxes, it is quite possible an *imperium in imperio* might last for a couple of months after swarming time, or even much longer. Again, Mr. Woodbury shows his candour in describing the fight which took place on his sending one of the queens to Mr. Fox.

HONEYDEW.—This sweet exudation rarely comes on the trees in August except in extremely hot dry seasons, when nearly all the best honey flowers have been prematurely hastened to seed. In 1846, it appeared to be very abundant between the 10th and 30th of June; in 1859, it appeared plentiful in parts of June and July; and in the last summer, in July, as mentioned by me before. But I must own that

A A A Are the posts.
B The door.

C A fowl entering.
D A disgusted and hungry sparrow

I have noticed in several seasons the wild bees (the Bombi), of various sorts have been much more eager after honeydew than the hive bees, particularly that on the young oak and beech trees.—H. W. NEWMAN, *Hillside*.

LIGHT-COLOURED POLLEN.

For the past fortnight and more I have been surprised at the great activity amongst all my stocks. Every day when the temperature of the air permitted them to leave the hives, they have, especially in the early morning, worked on something, but what I am not able to guess. They return to their hives literally covered with a very fine white powder, just as if they had been rolled in dark flour. They carry in at the same time pellets of farina of a dirty white. At first I thought they visited some flour-mill or baker's shop. I opened several, and was surprised to find the honey-bag contained a bright transparent fluid of a very high flavour. I know of no flower of any sort in bloom within a mile of my house, except some poor beds of Mignonette, which they now pass by; besides, the pollen of Mignonette is of a bright red colour. They fly in the direction of some chalk pits more than a mile away, where I have from a distance observed some yellow flowers in bloom. I shall be exceedingly glad to be informed from what this honey and farina is collected.—E. FAIRBROTHER.

[Our own bees likewise return dusted with white powder, and carrying loads of light-coloured pollen. We believe that this is the result of their labours among the great numbers of fuchsias now in bloom, from which also some honey is collected.]

AN EXPERIMENTAL APIARY.

IN a former article I said that "an experimental apiary can never be a thoroughly prosperous one." In enunciating this truism, I fear that some of your correspondents have misunderstood the object I had in view in making this statement, as well as misapprehended and misapplied its meaning. I had no wish to condemn legitimate experiment, far less to put a stumbling-block in the way of science. Experiment, I know, is often the torch which lights up the dark recesses of the unexplored world, discovers and reveals to us its hidden arcana, and dissipates and dispels the mist and gloom of a thousand years. Experiment is at once the discoverer and the test of truth; it is the key which unlocks to us many a treasure in the vast storehouse of creation, and opens up to us a solution of many a *questio vexata*, many a knotty problem. But experiment must not be confounded with science, nor error with truth. Experiment from the very nature of the case may be misapplied and fail in its objects and ends, and its success will always be commensurate with the knowledge which guides and directs it. A scientific apiarian and an experimental one, therefore, are not synonymous.

Do I blame Mr. Woodbury merely because he is an experimentalist? No. If I did I should be condemning myself, who, to attain certain ends and test certain theories, have often done violence to the principles of good management, and come knowingly into collision with the findings of scientific experience. So long as mystery remains a part of the natural history of the bee, experiment must be resorted to for the purpose of solving it. The means employed may not always be scientific or in accordance with nature, nor may they be promotive of the good and prosperity of the bee community; but as soon as our knowledge is complete then only shall we cease from experiment, and conduct our apiaries strictly upon scientific principles. But in the meantime it behoves us, more especially in the ordinary practical work of the apiary (and this is what I am at), to walk according to the most approved rules which experience and ascertained facts warrant. The more we do this we shall find our success the greater, our pleasure and profit the larger. Knowledge here, as in everything else, is power—it is the philosopher's stone, the true alchemy that turns everything it touches into gold, or, at all events, into its equivalent.

But after all is there such a difference between a merely experimental apiarian and a strictly scientific one? Let us see. Let me relate a few of the experimentalists' doings,

which may amuse, perhaps, what are called the old-fashioned apiarians, and cause some of the would-be modern class, who pursue with hot haste every phantom of novelty which crosses their path, to pause and ponder in their erratic ways. But where shall I begin? The field is so full of materials as to encumber my movements. I can only attempt to traverse a portion of it at present.

First as to domiciles. The experimentalist must try all sizes, from the giant tub of Duchatel, down to the puniest vessel which bees can be crammed into. He must also try all materials—straw, wood, glass, cork, earthenware, rushes, and sea-grass. All forms and shapes, too—the square, the oblong, the circular, the hexagonal, octagonal, pyramidal, triangular, and globular, the high and the low, the conical-topped, and the flat-topped, a unicom, and a decemcomb, a hive crossed with sticks, and without sticks, a frame-hive, a bar-hive, a vertical frame, a horizontal frame, and a leaf-hive, a hive 6 feet high, and one 6 inches. In short, he must try all kinds of materials, all forms, shapes, and sizes. Then, having got his bees domiciled according to his fancy—say in autumn, he tries to find out what kind of food is best to feed them with. Soft sugar, lump-sugar, candy-sugar, boiled, half-boiled, raw, foreign honey, home honey variously mixed and compounded; but a favourite dose may be thus stated—honey so much, sugar and ale so much, brandy, sherry, or rum so much, with a modicum of salt, and, perhaps, a little treacle added to give the whole more "consistency."

Having discovered that his bees are afflicted with dysentery in the spring (no wonder often), he must again have recourse to the bottle, and administer a glass of gin, diluted of course. But perchance he has heard something of "burying alive," and to save himself the trouble of feeding and his bees of eating, he digs a hole in his garden at dusk, and there and then he systematically buries his hives alive, carefully covering them over with leaves, earth, &c., and there they are left to their fate; but no reviving spring returns to awaken the poor bees from their deep slumbers. Or perhaps he has read somewhere something of the effects of position and aspect and internal moisture, and having failed in the bowels of the earth he tries the regions above—he tries an altitude of 15 or 30 feet, where he thinks no damp can approach them, and there they are left as an experiment till they are thoroughly winnowed. But the experimentalist is ever changeable as the winds that blow, and fearful of the evil influences of cold winds he tries all sorts of aspects—east, west, north, south; but as this would not suit the ever-varying current of our winds, the revolving pedestal will best meet his views, and hence, like a weathercock, the floorboard will always point leeward. By this method the bees will be afforded some amusement, to say the least of it, in finding out their doorway, and the virgin queen, if they ever become possessed of one, some reason when she ventures forth for going astray. Having heard something too of the disastrous consequences of hives being exposed to the bright rays of the sun in winter, and that they eat less honey and lose fewer bees by being sited on the north side of a wall where they are in perpetual shade, he tries the experiment, and the result is duly chronicled, of course; but in this as in many things else, observation is often fallacious, "*Experientia fallax*." Then comes the spring, and he discovers that some of his hives exhibit signs of weakness, while others are more active and healthy. With the view of equalising their strength he tries the effect of transposition of sites. This, he is informed, is a capital expedient, and always attended with the best results. Well, the issue will show, though not always to the experimentalist. Having some frame-hives, it may be, he is constantly in the habit of drawing up the frames for inspection, and he is surprised to find that the queen disappears some morning, or is found a stiffened corpse before the hive. How marvellous! Some of the Germans call this a case of regicide, I believe.

But now comes the swarming season—No, not the swarming season; I should rather say the driving season. "Artificial swarming for me," says the experimentalist; "I could not be bothered with natural swarming, it is too old-fashioned—Nature must be helped." "Artificial swarming is to be preferred to natural swarming," say the Potsdam conclave of apiarians, and the sentiment is echoed by many an Englishman. The spirit of the times is for speed—it cannot brook delay. The old slowcoach system will not do

now. No: we must transport our bodies by the speed of the railway, and our thoughts by a flash of electricity. The question with the experimental apiarian is not, "Are my bees ready to swarm?" but "Am I ready to force a swarm? Nature is tardy—she must be incited to action—she must be helped. I care nothing for natural swarming: twenty minutes' drumming is more pleasant to my ears than the aerial music of a rushing swarm." Is it really so? Can I believe it to be so? Speak out, ye lovers of nature—ye who profess to feast your eyes with delight on the beautiful landscape, whose varied charms the artist's pencil can but faintly portray, and say if artificial swarming can ever compare for a moment in this respect with natural swarming. I need not "pause for a reply;" I know your verdict. Deprive the apiary of natural swarming, and you deprive the true apiarian of his principal delight. Take away from it this exciting pleasure, and the mystical spell which has so often charmed the lovers of the bee in all ages is broken, and our minds will be brought down from the bright regions of poetry and expectancy to the mere commonplace considerations of profit and pelf.

But I must away back again to the enigmatical and the experimentalist. Ready, or not ready, he drives his swarm, and a swarm he assuredly gets, and his successes are, of course, duly recorded. But pray, Mr. Experimentalist, what of your failures? Be candid for once. Oh! but the experimentalist "does not allow of many failures." "There should be no failures." Well, be it so; I do not choose to lift up the veil as I might, nor must I be too inquisitive. The driven hive is removed to a little distance aside, and the new artificial swarm is put down on the old stance. Splendid treatment this for the old stock, whose remaining bees, I fancy, are sadly thinned-out sometimes during the following day or two by desertion! But that is nothing. Bees we are told will hatch, and grubs mature, and eggs preserve their germinating powers for several weeks in a greenhouse at a temperature of 50°, and that the grubs may there be nursed with our own hands till they quit their cells. If these things take place in a greenhouse, why not in this well-nigh deserted hive? The experimentalist by-and-by, however, discovers foul brood has been introduced somehow or other into his hives, and he is told, that though the old-school apiarians are generally much behind the present age in knowledge, yet their views of foul brood—that it is a disease, a pestilence, which originates very much like the potato disease, nobody knows how—must be received as correct, and that all new theories by whomsoever broached must be ignored altogether as erroneous. Moreover, that it is a disease of so virulent a character, as to infect brood, comb, honey, bees, and domicile, and, therefore, that the combs must be all consigned to the melting-pot, the honey carefully kept away from other bees, the domicile itself burned or laid aside for four years (would not three years and a half do?) purifying, and the bees and queen subjected to a sort of penal discipline and inanity for several days, until they are thoroughly purged of all gross and infectious matter, all which, nevertheless, may not prove effectual in extirpating the malady, and then the bees must be put into a healthy driven hive (it matters not though it has been deprived of its bees the day previous), and all will be well. "The chilled and neglected brood in all stages in this hive will suffer little or no harm for a day or so, the actual mischief being very trifling. Neither the eggs, very young brood, nor that which is sealed over, is at all injured." Say, ye scientific apiarians of this the nineteenth century, with all your experience, is it even so? Are chilled and neglected brood so removed? Tell it not to the apiarians of Scotland, who dwell in the land of the mountain and flood. Publish it not in England amidst its comparatively warmer vales and milder clime. Repeat it not in the pages of THE JOURNAL OF HORTICULTURE, whose fame on apiarian subjects is known and appreciated from Land's End to John O'Groat's. No: Decayed and abortive brood in all stages are not removed by the bees, and, consequently, must remain a permanent evil, in whichever hive they are unfortunately found.

But I must draw this already-too-long paper to a close. The field, as I said at the commencement, is too full of material to be exhausted in a few columns; besides I cannot traverse it without trampling on peoples' toes, and this is not agreeable. I therefore must forbear. My "tone and

style" are already thought by some to be too severe; and it appears, though I must receive contradiction, I must not be given to "philippic," and to "giving pokes in the side." Nor have I done so. In opposition to the old theory of foul brood I have propounded my views on the subject. It is an evil with which I have been long familiar, and I have not found its eradication at all so formidable an affair as is represented. I have found that an excision of the affected parts is sufficient; but care must be taken that it is complete. Nay, since writing these articles I have, as an experiment, totally extirpated it from a hive by thoroughly cleansing (at a considerable tax upon my patience and time), each affected cell; while both in my own apiary and in that of a friend some sixty miles distant, I have seen the evil produced again and again by a few manipulations.

Let me in conclusion assure "B. & W.," whose uplifted mask has revealed to me a more familiar name, and all others who have entered the lists with me in this *questio venata*, that I had no other object to serve, no other motive to gratify, no "other interests" at heart, but the elucidation of truth and the maintenance of such sound principles of apiculture as not a little observation and experience have taught me to value, and which I have been presumptuous enough to recommend to the consideration of others; who, no doubt, desire with myself, both on economical and scientific grounds, to see the natural history of the bee and its management freed from the errors and disencumbered of the prejudices which have so long encompassed them.—J. LOWE.

PARTHENOGENESIS—DRONES—DRIVING.

THE letter from Mr. Alex. Shearer, in page 283, shows that your nautical cry of "no nearer" must be attended to by us all. If I am an unbeliever in parthenogenesis, I am one ready and willing to be convinced of the truth, and I take for granted "A DEVONSHIRE BEE-KEEPER" wishes only that the truth should prevail, and would rather be convicted of error in past opinion than continue to advance any theory that will not lead on to fact. My supposition with reference to the matter in question is, that eggs of queens or workers—if it be established that the latter lay eggs—can be rendered fertile by some other than the usual method. Eggs of fishes certainly are, and why not those of bees? I have seen drones clustering in such numbers on comb that I have imagined it possible they might deposit spawn in the bottom of certain cells, and hence a reason why eggs of virgin queens placed in those cells by workers might vivify. Has the microscope shown any difference in the eggs that produce queens, workers, or drones? I had drones hatched much earlier this year in a hive than I ever saw them hatched before, and I imagine the reason was clearly this—that I had during the year previous placed a small piece of drone-comb as a guide in a small box at the top of that hive. This small box was filled with drone-comb, and I observed that drones were always clustering in large quantities in that small box. (There were three other boxes alongside this one in which the case was different.) This year, being at the top of the hive, it was presently filled with brood, all drones, and hatched out its young much earlier than if it had been at the bottom of the hive, where drone-comb is usually made. This raises a question: Can the queen mother lay her eggs as she chooses?—queens, workers, or drones; workers, drones, queens; or drones, workers, queens, &c. The number of drones in comparison to the queen shows that Creative Wisdom must have had a reason for the disparity, so that I may be pardoned for my surmise that there must or may be some other way of accounting for their use than to suppose they all engage in fertilising the queen. If the "DEVONSHIRE BEE-KEEPER" would think this over and reply in any way I should feel obliged. I am not able to try experiments as he can and does. He may laugh at and despise me if he will; but I confess I have just tried my hand, moved thereto by the taunt of the "LANARSHIRE BEE-KEEPER," at driving some bees for comb and honey that I desired for myself and friends; and so signally did I fail that, after half-an-hour's hammering and tapping, I was forced to give it up and fume the bees out.—A HAMPSHIRE BEE-KEEPER.

[Our Hampshire friend does me no more than justice in

believing that truth is my first object, and that if I found myself in error with regard to parthenogenesis I should lose not a moment in recanting and doing my very best to guard others against a similar mistake. No one could be more incredulous than myself when the subject was first broached; but a perusal of Von Siebold's work having convinced me that there was at least a strong case in its favour, I at once set myself to verify it by such observations as were within my reach. These soon satisfied me that the doctrine was correct, and when called upon by "INVESTIGATOR" to give a reason for the faith that was in me, I was enabled by the kind assistance of my friend Mr. J. U. Huxley, to repeat and verify sufficient of Von Siebold's microscopic investigations to place the matter beyond the possibility of a doubt.

The hypothesis suggested by "A HAMPSHIRE BEE-KEEPER," appears to have been first promulgated by Maraldi about the beginning of the last century. It was adopted and confirmed by Mr. Debray, an English naturalist, who after a long series of experiments did not hesitate to advance as a demonstrated fact, that male bees fecundate the eggs of the queen in the manner of frogs and fishes—i.e., after they are produced. This occurred in 1777, and Debray's theory appears to have reigned undisputed until his experiments were repeated and his doctrines finally exploded by the illustrious Huber in 1789. I say finally exploded, for I think few intelligent readers could have been inclined to listen to the senseless objections subsequently raised by Huish to the discoveries of Huber, or his equally senseless attempt to galvanise into life the defunct theory of Debray. The most decisive blow to any lingering remains of the doctrine of post-fecundation by drones has, however, been administered by the Ligurians, since it has been found that on the installation of an Italian queen in a hive of black bees, every young bee after the lapse of twenty-one days is a pure Ligurian, in spite of the existence of a multitude of black drones within the hive at the time.

It may be that all these particulars are as well known to my Hampshire correspondent as to myself, and if so, I ask his pardon for a digression which may, however, not be without interest to some among the readers of THE JOURNAL OF HORTICULTURE, and I will without further preface reply to the queries propounded to me.

In the first place, then, we may take it as an unquestionable fact, that under certain exceptional circumstances worker bees can and do lay eggs which are capable of hatching into drones. Setting aside the evidence of bygone apiarists from Riem downwards, it has been abundantly proved by repeated instances which have come under my own observation, to say nothing of those related by Mr. Shearer. That these eggs were not post-fecundated will become apparent when I state that not a single drone existed in the hives in which they were laid and developed. That the eggs of drone-laying virgin queens, also, are not post-fecundated is even more conclusively proved by the fact, that I have on three different occasions had them laid and hatched so early in spring that not a single drone existed in the apiary at the time, nor had one been present since the preceding autumn.

It has been established beyond a doubt that the eggs which produce queens or workers are absolutely identical, and in these, of course, even the microscope fails to detect the slightest difference. The distinction between worker and drone eggs long baffled the researches of Leuckart and the most distinguished microscopists, but was ultimately made apparent by Von Siebold, who, by a peculiarly felicitous manipulation, was enabled to demonstrate the existence of spermatozoa in the female or worker egg, whilst he proved them to be entirely wanting in those which would produce males.

The placing drone-comb in the centre of the hive or "brood-nest" is constantly resorted to by myself and other scientific apiarists when drones are wanted in early spring. Its presence in that position, combined with liberal feeding and strength in the colony, seldom or never fails in securing the desired result. This fact proves indisputably that queen bees are, like other mortals, very much the creatures of circumstances; but I doubt whether it be sufficient to raise a question in their case as to the doctrine of free will.

That the Great Creator does all things well is as manifest in the multitude of male bees when compared with the

number of perfect females, as in the rest of His works. It must be remembered that a colony of bees is designed to be in all respects a self-sustaining community. The congregation of a number of stocks within a few feet of each other is an entirely artificial arrangement, and one which would probably be quite exceptional in their wild state. Take, then, what I may term the natural condition of an isolated colony, and reflect how important it is that the individual upon whose life the very existence of the community depends should peril that existence as seldom as possible in unavailing flights in search of a mate; we shall then see that what, in our shortsightedness, we may have been tempted to call a useless multitude of drones has not been created in vain, and bow down before the wisdom of that Almighty Being who holds all things small as well as great in the hollow of His hand.

When many stocks are congregated together the necessity for a great number of drones in each hive is, of course, very much diminished, and a limit may therefore be advantageously put to their production. This is readily done in frame-hives by removing most of the drone- and substituting worker-combs. The opposite result may also, as I before stated, be obtained with equal ease by the insertion of drone-combs in the "brood-nest."

I can neither laugh at nor despise my Hampshire contemporary for failing to drive a stock of bees, since by so doing I should be heaping ridicule and contumely upon my own head. Let him turn to page 52 of the twenty-first Volume of THE COTTAGE GARDENER, and enjoy as hearty a laugh as he pleases at my expense whilst he peruses a description of the failures and difficulties which attended my first attempts at driving bees. If the perusal should incite him to persevere he will doubtless (like myself), succeed in the end. If not, what would he say to my calling-in upon him whenever I next visit the metropolis by South-Western Railway, and giving him the benefit of the example in addition to the precepts of—A DEVONSHIRE BEE-KEEPER?

HONEYDEW.

LIKE "B. & W." I am a little sceptical about the bees making much of the oak when covered with honeydew. I indeed have seen them working often on it, but I never yet saw them make themselves any heavier of it. Last year a great cry was raised amongst the apiarists here that the bees were doing well on the oaks in August; but I am sorry to say that it had only been a fly with them because they made no weight. Like "B. & W." also, I have noticed more or less of it every summer at different times; but it never continues long at a time—perhaps about three days—because it never occurs unless in very hot weather, followed by thunder-storms which wash it away. Perhaps if it remained long enough the bees might collect it. Still I am afraid it is a bad sign when they frequent the oak.—A LANARKSHIRE BEE-KEEPER.

OUR LETTER BOX.

MR. J. C. FREELY, *Gedling, Nottingham*.—We are asked for information about this person.

POULTRY FOR PROFIT (A. B. C.).—As you wish for first-class birds of pure breeds, read the reports of the poultry shows and write to the prizetakers, purchase from them—pullets from one yard and cockerels from another. Cochins-Chinas and Brahma Pootras are most profitable for eggs, because by disposing of the hens annually and having early pullets in their place, you will have eggs in winter when they are dearest. For eggs and table chickens we recommend Cochins-China or Brahma Pootra pullets and an adult coloured Dorking cock. Silver Grey Rabbits and the common Dove-house Pigeon are the most profitable. The skins of those Rabbits are valuable, and their bodies are good for table.

FOWLS WITH DISEASED LIVERS (M. A. M.).—The fowls are evidently suffering from disease of the liver, which at length kills them. This is often hereditary in poultry. Drive them out of the cage-yard into the field. Keep them short of food, feed three times per day scantily. Let the food be ground oats or barley meal, slaked with water, and scattered abroad on the grass. Kill all the old diseased birds. Save the healthy and promising hens and pullets. Do away with all the cocks running with them, and turn in fresh ones in December. This disease often arises from over-feeding, especially with meal.

COCHIN-CHINA COCKEREL (Inquirer).—The weight you mention, 9 lbs. 14 ozs., is good for a cockerel six months old. He will become heavier if healthy.

NORFOLK ORNITHOLOGICAL SOCIETY (A Subscriber).—Its exhibition should be advertised. Many fanciers out of the county would exhibit if they knew about it.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 54.6°, and its night temperature 37.6°. The greatest heat was 67°, on the 29th and 30th, 1833, and 31st, 1854; and the lowest cold, 22°, on the 2nd, 1860. The greatest fall of rain was 1.06 inch.

THE GLADIOLUS AND ITS FAILURES.

UCH it is to be hoped that the inquiry now going on in the columns of THE JOURNAL OF HORTICULTURE regarding the disease or causes of failure in this popular flower, may lead to some practical remedy or preventive; and if every one whose bulbs have become diseased during the past season would report the particu-

lars of his case, we might then be able to ascertain if the failure has arisen from causes that are preventable, or from some constitutional debility or cause over which we have little control.

The supposition of a correspondent, "T.," at page 288, is certainly not an unlikely one; indeed it is utterly hopeless to expect a good bloom—or, in fact, any bloom at all—from a bulb which has been deprived of half its juices before planting time, and the best growing period gone ere it was planted. An old Potato planted in July or August does not produce so good a crop as one put in the ground in April; and in like manner the Gladiolus, though it will flower in the same season that it is planted if the ripening of the bulb has been well perfected the year before, yet, if the planting be delayed until there is no longer time for flowering as well as perfecting the bulb, the latter cannot take place, and a flowerless growth will be the result in the following season.

On the other hand, are there not cases in which well-ripened bulbs have failed, after commencing their growth apparently under favourable circumstances, and all has gone on well until a certain period, when they dwindle and die off? If this be verified, we must look to something else as the cause of failure, and perhaps we may discover its origin and some means of prevention.

My own experience with the Gladiolus has not been such as to enable me to give a confident opinion on the causes of failure, as I have less reason to complain of it than most people; and these cases might in some measure be attributed to the unfavourable position the plants were in. I will, however, give the cases which probably will interest those who, like myself, are anxious to know why perfect success cannot always be depended upon.

In the first example, in the spring of 1861 I bought a quantity of *Gladiolus gandavensis*, and planted the bulbs

in a bed that had been prepared for the hardiest varieties of Indian Azaleas. It was mostly leaf mould. The situation was a dry one, and they received no artificial watering. They were planted in patches of three bulbs together amongst the other plants, some Japan Lilliums being in the same bed; but these Lilies evidently wanted more moisture, although they flowered not amiss. The Gladiolus, however, flowered well, and I did not disturb the bulbs that autumn, but they remained as they were and flowered well in 1862 also. Circumstances also prevented the bulbs being meddled with last autumn, one of the principal being a carelessness whether they did well or not, as the brighter colour of *G. Breuchleyensis* obtained for it a decided preference, so they were left to flower the third time where they were first planted, which they did tolerably well, though evidently requiring to be taken up and replanted on other ground, as the flowers were smaller. I may observe that some of the same kind of Gladiolus had been grown elsewhere before the above were planted, but being taken up annually their case does not require to be noticed. I find, however, that *G. gandavensis* is much harder than *G. Breuchleyensis*, as some of the latter which were left out last winter in the same manner as those already spoken of either fell a prey to insects in the ground or did not possess sufficient vital power to resist the decaying influence of the long winter's damp. More than three-fourths of those left in the ground during winter failed to make their appearance in the past season. The ground, I must observe, was a deep loamy fresh soil far from being so dry as the other, at the same time not wet; in fact it was what might be called good land. The bulbs flowered well last year, and what remained flowered well again the past summer; but I imagined the bright scarlet of the original was in a measure impaired or lessened so as to be, in many of the spikes, no better than *G. gandavensis*. Might I ask if this has been the case elsewhere? Some other bulbs planted in another part of the garden turned out variously, some of them well, and others grew away until about the period when the flower-spike ought to have made its appearance, when they withered away. This was sometimes the case with a whole patch, or sometimes one or two bulbs would so succumb and the third flower tolerably well, which circumstance leads me to think that the disease, if it is one, is not infectious. I believe, however, that we have had fewer failures than have been met with elsewhere, but I cannot yet give a decided opinion on their cause, and have only recorded them for the benefit of others making comparisons, and whose experience I hope will duly appear in the pages of this periodical.

Although I have had some opportunities of seeing this plant at other places, I confess that I am unable to give any opinion on the subject of soils as affecting it. In the Manchester Botanic Garden I saw two excellent beds of it in the best possible health and promising to bloom well, as the spikes were well formed and some of the flowers ready to open when I saw them in August. These, I have no doubt, flowered well, I did not perceive any failures

beyond one or two which might be accidental, the general foliage still being green, and Mr. Findlay, the intelligent Curator there, justly expected they would be very gay in a few days afterwards. The soil was the dark sandy one common in the district; the situation was unfortunately too near the city for the welfare of most trees and shrubs cultivated there, and they were evidently suffering much and yearly becoming worse as the amount of coal smoke kept increasing on all sides.

The proverbially rainy character of the district had in the early part of the past season been in some degree reversed, and May, June, and July, were said to have been much drier than usual, but the situation of the Gladiolus-beds in the garden was not one where the plants were likely to suffer much from that cause. As I have stated, they looked well, though they fell short of the vigour and robustness of growth of another bed I saw in the same neighbourhood, but farther removed from the smoke.

At Fog Lane in the suburbs of Manchester, Mr. Cole, one of the most successful exhibitors of plants at the London and other shows, has established a nursery, and amongst other things was a bed of *G. Brencleyensis* in the most promising condition I ever saw, the foliage being a deep green to the very tips, and the knotted spikes of bloom promised to be very sturdy and thickly set. Mr. Cole attributed his success in a great measure to the application of liquid manure, which he had given at various times during the season, and there could be no doubt whatever of the beneficial effects it produced, as an adjoining bed of the same kind which had not been so treated, was much less promising although at the same time looking well. The soil was much the same as that in the Botanic Garden, a black soil containing more sand than is usually met with elsewhere, and I believe of sufficient depth to meet all the requirements of vegetation. It was certainly richer in unctuous matter than the peaty soils of some districts famed for Rhododendron-growing, although the latter seem not unfitted to the growth of Gladioli, but I had not an opportunity of witnessing both at the same time.

More recently, however, I saw in one of the Bagshot nurseries a bed of Gladioli, which of course had done flowering some time and were ripening down, but they appeared to have flowered pretty well. I must confess having heard great complaints about the plant in some places, and it would be well if all the facts bearing on the cases where failures have occurred could be laid before us, and if the evil be found to arise from bulbs imperfectly ripened in the preceding season, some means may perhaps be adopted of avoiding it, for, to use an old trite saying, a knowledge of a disease is half its cure, and this case need be no exception to that rule.

J. ROBSON.

AMMONIA IN THE ATMOSPHERE OF HOTHOUSES.

THE following is Mr. Thomson's reply to several inquiries upon the subject.

No doubt the atmosphere could be charged with ammonia in many ways besides that of applying guano water to the pipes, or sprinkling the surface of the soil or floors of hothouses with the same. The solution formed by pouring water on guano holds in suspension the ammonia and a very small proportion of the phosphates. The organic matter sinks to the bottom; hence the application of guano water need not be a dirty operation, there being no necessity for applying the sediment to pipes or flues, while at the same time there need be no waste, as the organic matter may be applied elsewhere as a manure. No doubt sulphate of ammonia, which is readily soluble in water, might produce the same result; so would ammoniacal water from the gasworks, from which ammonia in the very concentrated form of hartshorn is now obtained. I am inclined to think that the application of guano water is safe and wholesome as well as the least troublesome way of producing ammonia in the atmosphere of a hothouse where tender plants are grown. We apply it regularly here in our Pine-pits in a very diluted form, yet sufficiently strong to be discovered whenever the atmosphere of the pits reaches the olfactory nerves. I fully believe that the composition of the atmo-

sphere of our close hothouses is yet a field where there is much to be done. It should always be borne in mind, however, that it can only be after many experiments and long practice that any of our highly concentrated salts, such, for instance, as muriate of ammonia and hartshorn, can be applied properly and with benefit.—D. T.

NEW ROSES—No. 2.

IN resuming this subject, so fertile in grumbings and complaints as all growers for sale can bear witness, I may observe that another commentator, while viewing the subject from a different stand-point, arrived at very much the same conclusion. My object in referring to it is only to show that the same sort of feeling is pervading the minds of a great many rosarians at the present day, and that it would be a great boon if a stop could be put to this wholesale French invasion to which England is subjected every year; but the temptation is one which even our own raisers cannot resist. To have two or three Roses, by which, perhaps, the owner makes £200, is for any one, but especially a French nurseryman—who, whatever his Emperor may do in war, certainly does not grow Roses for an idea, but for a pretty good consideration—a thing which it requires uncommon virtue to resist. The day may come when a change may arise, but till then we must, I suppose, "bear those ills we have." And now to resume the revision of the lists.

GRANGER.

25. Baronne Pelletan de Kinkelin! beautifully shaped and imbricated; red, shaded with purple.
26. Kate Hansburg, cup-shaped; lively rose.
27. Leopold Hansburg, red, shaded with brown and purple.
28. Louis Van Houtte, globular; carmine rose.
29. Sœur Oppenheim, carmine red, shaded with purple and violet.

M. Granger is the raiser of that fine Rose Maurice Bernhardt, and I should think, therefore, knows what a good flower is; if so, then 25, albeit its outrageous name, is likely to be an acquisition. So is 26. 27 I should doubt the colour of. 28 Sounds well. 29 I should not consider much, it is hardly likely that five good Roses should come from the same raiser in one season.

LACHARME.

All honour to the raiser of Charles Lefebvre, well does he deserve to have that fine Rose François Lacharme called after him; and as a modest man, as no doubt he is, he sends out but one Rose this year.

30. Gabriel de Peyronney, fiery red, shaded with violet at the centre; full, and of fine form.

I think this may be regarded as likely to be an effective Rose.

TOUVAIS.

31. Centifolia Rosea, rose colour.
32. Jean Touvais, purple rose, shaded with crimson.

I do not think that either of these promises much, and we never have had much from M. Touvais, so I should decidedly mark these out of the list.

PERNET.

33. Gloire de Sacré Cœur (what a name! who but a Frenchman would ever have thought of it?), flesh rose, shaded with red and purple.
34. Maréchal Canrobert, lively rose, occasionally shaded with purple.

M. Pernet's name is unknown on this side of the Channel, I think, and I should, therefore, have much hesitation in trusting his description.

OGER.

35. Charlemagne, lively cherry red.
36. George Senior, brilliant reddish-crimson.
37. Madame Malherbe, blooming in clusters; lively rose.
38. Marquise de Bruges, crimson velvety red.
39. Michael Ange, lively reddish-purple.

M. Oger has the singular modesty to charge only 15s. for his Roses; but as we have not had any Roses that I recollect of his that are worth much, I can hardly give him the credit of believing that it is all modesty, and his Roses, therefore, would be put in my discarded lot.

DUCHER.

40. Benoit Cornet, lively red, lighter in the centre.
 41. Le Mont d'Or, shaded carmine red.
 M. Ducher is the raiser of Robert Fortune, Deuil de Prince Albert, &c., but none of his Roses have taken a high place amongst us, and I therefore feel inclined to doubt their excellence.

DAMAIN.

42. Louise Damaisin, not very full, white; blooming in clusters.
 43. Madame Maeker, white, slightly tinged with blush. A seedling of Mère de St. Louis.
 44. Maréchal Suchet, rosy carmine; large and full.
 45. Sénateur Reveil, brilliant crimson red, shaded with dark purple.

M. Damaisin has given us some good Roses, and we may, therefore, hope that one or two of the above may be good. 42 Seems too thin. 43, Mamma is no very great lady, and I should, therefore, look rather to 44 and 45 as the best of these; the latter especially, if description is worth anything, seems as if it would be worth growing.

LEVEQUE ET FILS.

46. Madame Derrealx Douville, tender rose, edge of petals white.

This is the only Rose that the raiser of that fine Rose, Duc de Rohan, has his name attached to this autumn; but I believe he sends out some others also. This hardly seems as if it would add to his reputation much.

LIAAUD.

47. Arlès Dufour, large and full, purple, shaded at the centre with violet.

48. Madame de Canrobert, large and full; white, slightly tinged with lilac.

Neither of these have colours that are likely to take with us, and I should not, therefore, consider them as likely to be acquisitions.

PORTEMER FILS.

49. Madame Soupert, very full, imbricated; white, slightly shaded with blush, passing to pure white.

50. Pierre Notting, very full and globular; very dark blackish-red, slightly shaded with violet.

Portemer is so honest a man, and so good a judge, that I should hope one if not both of these Roses would turn out to be good. 50 I fear is of too dull a colour to suit us, unless the description be intended to signify a different sort of flower to what I imagine it to be.

BOYAU.

51. Mademoiselle Adèle Launay, beautiful rose; blooming freely in autumn.

This sounds well, and as new flowers of a rose colour are scarce, I should hope this may be an acquisition.

GONOD.

52. Vicomtesse Douglas, cupped; beautiful rose, reverse of petals silvery.

This is another of those two-coloured Roses which I do not think will ever be favourites with us. Since I wrote my notes on Duchesse de Morny, I have received a plate of it from M. Eugène Verdier, and it does not certainly give one very enticing notions of what it is likely to prove, or alter my opinion that there ought to be no contrast between the upper and under side of a Rose.

FONTAINE PÈRE.

53. Souvenir de Maréchal Serrurier, beautiful vivid red, back of petals whitish. The same remark applies to this as to 52.

I have now waded through these long lists, and given my opinions such as they are, as I have gone along. Which, then, are likely to be the best, the *crème de la crème*? I notice that M. Margottin admits besides his own into his select list, only twenty Hybrid Perpetuals. These are Abbé Reynaud, Alpaide de Rotahier, Alphonse Belin, Amiral La Peyrouse, Baronne Pelletan de Kinkelin, Eugène Verdier, George Paul, George Prince, La Duchesse de Morny, Leopold I. Roi des Belges, Louis Van Houtte, Louise Damaisin, Madame Soupert, Madame Victor Verdier, Madame Gabriel de Peyronney, Maréchal Suchet, Pavillon de Pregny, Paul de la Meilleray, Pierre Notting, Sénateur Reveil,

Souvenir de Maréchal Serrurier, Triomphe de Villecrenes, and Vicomtesse Douglas. I could still further reduce this list, and look for the best amongst the following:—In Bourbons: Madame Clotilde Perrault, and Révérend H. Dombrain. In Hybrid Perpetuals: Alpaide de Rotahier, Triomphe de Villecrenes, Bernard Palissy, Maréchal Forey, George Paul, Pavillon de Pregny, Amiral La Peyrouse, Baronne Pelletan de Kinkelin, Madame Gabriel de Peyronney, Sénateur Reveil, and Madame Soupert. Time alone can tell how far wrong one is. And now a word as to *Teas*, of these there are three.

Jaune d'Or (Oger), globular, full; golden yellow.

Lays (Damaisin), sulphur yellow.

Souvenir de Madame Eugénie Pernet (Pernet & Co.), blush, shaded with rose and salmon yellow; very hardy.

All these succeed very well, especially the last. We may hope that this interesting class may receive the same good additions this season. There has not been much advance in it these last few years, and it will ever be a favourite class especially with ladies.—D., *Deal*.

TRENTHAM.

THIS magnificent residence of his Grace the Duke of Sutherland, is situated about a mile from the station of Trentham, and about three miles from that of Stoke, farther north on the North Staffordshire Railway; and close to, almost forming a part of the latter station, is a large, commodious, comfortable hotel, a matter of importance to those that may arrive late for the purpose of seeing Trentham on the following day. It is just a nice walk from Trentham station to the garden, and the visitor will be pleased to note several picturesque cottages with their flower gardens, and summer creepers mantling the walls, as he passes along.

Trentham might well be denominated "The Lily of the Valley," the building and demesne showing, in their simplest details, the refined taste of the Dowager Duchess, and the architectural and artistic touches of a Barry. The gorgeous mansion is placed on low level ground, not far from the rise of the Trent, the banks of whose waters will ever be classic earth so long as the sweet though melancholy odes of Kirke White hold their appropriate place in English hearts. The mansion is backed on the west or entrance-front by a bold undulating park, terminating in the heights by the massive Henchurch Woods. The park itself was clothed with groups of deciduous trees, relieved by masses of lofty Scotch Firs, and enlivened by deer and cattle up to their knees in herbage, the grass seeming a stranger to the great drought from which our pastures suffered further south; and it was enlivened still more by the companies of well-dressed people who have next to free access to that part of the demesne. The mansion is backed on the north by the necessary offices, and on the east by plantations and shrubberies, which thoroughly conceal the kitchen gardens and forcing grounds, though close at hand, and which are reached by an iron bridge and a ferry boat over the river. It is fronted on the south by a series of Italian gardens on different levels, occupying a space, we should judge, of about a dozen acres, and these are fronted again by a beautiful irregular picturesque lake of eighty-four acres in extent, and relieved by several islands. This lake is bounded on the east or garden side by a continuation of massive lawns and shrubberies, marked by great diversity of outline and of planting, the kept grounds extending to somewhere about eighty acres, one place showing the careful hand of the artist, and another as plainly revealing superior taste, in allowing flowers, and shrubs, and trees to contend on the principle of "natural selection" as to which shall gain the superiority. We have often seen Clematis and Honeysuckle hanging in such elegant festoons from trees on the sides of the roadway, that it would be a very difficult affair for the finest art to imitate them in their gracefulness. The lake, again, is bounded on the west by what I have always considered the chief glory in a natural point of view of Trentham—namely, a fine Oak wood rising tier above tier like the steps of a colossal amphitheatre, that amphitheatre of wood, but more varied in foliage, seemingly closing in the south side of the lake. On a high crest of this wood, to the south is placed a fine statue of the grandfather of the present Duke, after Sir F. Chantrey,

elevated on a lofty column so as to be seen from a great distance, and erected to his memory, as the inscription tells us, by a "mourning and grateful tenantry."

From the green sward around the base of that statue, kept as it ought to be with scrupulous neatness, and some hundreds of feet above the water level, you look down on the mansion and its offices, the Italian gardens, and pleasure grounds, the lake and its pretty islands, and the silvery specks of white swans sparkling on its bosom, as if you were examining the details of a map or the beauties of a favourite painting.

Southward still from this wooded hill of the monument, a large width of elevated picturesque scenery extends for miles, almost close to the town of Stone, abounding in such numbers of beautiful green lanes or drives, that the stranger could scarcely fail to lose himself in them, and so massive are the groups of Purse and the ranges of Heather of different colours, that but for these, perhaps, too well-kept drives and the luxuriant fronds of the bracken, we might have fancied ourselves wandering amid the bleak mountains of the north of Scotland. Many of the trees in this waste have been planted without any assistance from man; but much has also been done to add the beauties of diversity of foliage to the scene, by planting masses of one kind of tree in one place, and others quite different in another prominent place, though there has been much to contend with from the somewhat wild deer that conceal themselves amid the Fern, and the flocks of rabbits that keep whisking out of sight at every turn. The groups of most of the commoner trees are doing well, and fine masses of Thorns, Laurels, Hollies, and Rhododendrons, &c., are beginning to tell the effects they will produce, whilst in other places the finer of the Pine tribe, Arancarias, and Podars are thriving delightfully. Upon such exposed heights they will have little chance of being injured by such frosts as those in 1860 and 1861, which destroyed so many fine specimens in the low sheltered grounds in the valley.

Amid such height, woods, and wilds, it would be easy to fix upon beautiful situations for a castellated mansion, commanding an extended view of the surrounding landscape, that fact, as well as the strength of its position, forming a security against the sudden fray and the warlike raid. The very tame, low position of the mansion, with no views from its windows but its own rich gardens, lake, and woods, and no apparent means of defence, seem to speak to us of days of peace, progress, and an advanced state of civilisation, in which ease of access and plenty of the conveniences and luxuries of life are more considered than the means to repel a hostile attack. If, unfortunately, amid the changes of the future such an attack should ever be made, it is to be hoped that there would be no lack of defenders. The warm heart blood of the tenantry that erected the monument still courses in the veins of their sons. During the last great agitation with which our loved country was afflicted, rendered all the more distressing on account of the hardships and privations so many of the working people were compelled to endure; and when, amid the dense populations of the potteries, there were mutterings about sacking the residences of the gentry and helping themselves, to the lasting honour of all concerned be it recorded, that great numbers of these hard-fisted men from the potteries (I forget now the exact number), without receiving a hint from any one, of their own free will and accord, and without expected fee or reward, marched to Trentham and constituted themselves a guard around the demesne, so that not even an outpost and far less any of the rich treasures of rarity of beauty and of art within the mansion should be touched by the hand of the spoiler. One of the most delightful signs, nay, facts, of the present day is, that so many of our nobility and gentry urged, no doubt, partly by feelings of benevolence, but chiefly by a deep impression of responsibility, are practically acting as if they thoroughly believed that the best security for their honours, and for the safety and preservation of their property, was to be found in the comforts, the contentment, the warm hearts, and the affectionate sympathies of the working people in their respective neighbourhoods.

With this meagre outline, and omitting all notice of the lake, the farm, and the large tracts of well-cultivated land held by the tenantry, I shall now enter into more definite details

and chiefly as respects gardening in its varied branches. I have already intimated that the kitchen garden is on the east side of the mansion, but though close at hand nothing of the latter is seen from the former, except part of a lofty open tower fully 100 feet in height. One peculiarity is, that unless when close to the walls, the kitchen garden is so banked and flanked with shrubberies, and its main walks are so skirted with flowers, that the idea of pleasure grounds is at first sight thrown over the whole. The entrance on the north-east is by massive gates with huge stone balls on the top of the pillars, and a drive through a shrubbery takes the visitor up to the gardener's house, situated near the middle of the north side of the main garden. On the south and west sides of the house is an open space of gravel enriched with raised beds, covered with Ivy, and planted with Geraniums, and centered with noble plants of *Humea* elegans. The road from the entrance goes on westward, at the back of a range of lean-to buildings, with the main range of glass houses in front, facing the sun at about half-past eleven. North of this roadway all the way from the entrance-gate, but flanked and concealed partly by shrubberies, and arrived at by crossing a brook, is a village or two of plant-houses, forcing-pits, workshops, &c. These, again, are backed by shrubberies, the cottage or children's garden, and these by shrubs and plantations, concealing the mansion and the river between until we get to it.

The garden is said to be five acres in extent, and we should imagine fully one-third of that to be under glass. We should consider it very small for the wants of such an establishment, but learned that most of the coarser vegetables were cultivated elsewhere. This permits of a greater degree of regularity and of neatness than can always be obtained in a garden where everything wanted must be grown. Whatever may be said in praise of the mansion nestled in the vale, and thus knowing but little of the huge chimneys a few miles distant, early vegetables and fruits find the disadvantage of such a low position, and in such close proximity to the river and the lake, with their attendant fogs and frosts, disadvantages which only served to whet into greater activity the abilities and genius of a Fleming, and the energy and the enthusiasm of a Henderson, without which accessories Trentham could never have held the position it now does as to its gardening. When we admire results we should also think of the difficulties that have been surmounted by drainage, superior cultivation, and never-ceasing care. But even with all these, loads of fine Rhododendrons and the finer of the Pine tribe were destroyed in 1860 and 1861, though escaping uninjured at higher elevations.—R. F.

(To be continued.)

GARDENERS' NAMES OF FLOWERS.

I was very glad to see my reverend and most able brother "D." of Deal, write as follows on the above subject:—"I am not inclined to agree with the notion that we must pronounce names of flowers as gardeners have done."

With the utmost respect, and in some cases reverence for the practical skill and scientific knowledge of gardeners, yet I humbly think it would be a retrograde day in horticulture if gardeners' pronunciation of the names of flowers was received by the classically educated as correct. There would arise this among other difficulties, "Where should the line be drawn?" If the verdict of a peer's gardener was received, why not that of his neighbour the squire's? But hall and rectory are often related, its inhabitants branches of the same family: why not, then, the word of a clergyman's gardener? Again, if so, where should we stop? I have constantly heard gardeners call the Rose "*Géant des Batailles*" "*Genty Battle*," and even (it was a beer-loving fellow) "*Johnny Bottle*." I have also heard the "*Bon Chretien*" Pear called "*Bun Christian*." The other day a lady, very particular about the correct pronunciation of names, told me that her gardener would call "*Cyclamens*" "*Sicklyluns*," and upon asking him to give them in future their right names, he replied, "Well, ma'am, they are such '*sickly uns*' that I think it is a very good name."

Now these I at once grant are extreme cases; but surely it is right in this, as in all instances, to endeavour to raise men to the correct standard rather than sink the standard

for the sake of men, which I fear would take place if we accepted gardeners' pronunciation. I feel sure that well-educated gardeners (and I am pleased to notice how these are increasing), will say Amen to my remarks, and feel that I am not writing anything in the least degree offensive to the gardener class. At the same time, I fear the godfathers of new plants little think of the trouble and perplexity they are causing the gardener world by giving their floral children so frequently names hard to be pronounced. Even the French Rose-growers might show a little mercy to English gardeners in this respect.—WILTSHIRE RECTOR.

PRONUNCIATION OF GLADIOLUS.

In a communication which you did me the honour of inserting, at page 250, I attempted to justify your pronouncing *Gladiolus* with the accent on the second syllable; and the authority on which I grounded my opinion was a rule given in an edition of the *Eton Latin Grammar* by T. W. C. Edwards. The correctness of that rule has not been impugned by "D." nor by any other man that I am aware of. Will your correspondent undertake to prove its falsity, or that it is inapplicable to the word *Gladiolus*? Until that is done I must presume that the rule stands good, and that, according to it, the accent will fall on the antepenult, which is the second syllable in the word, and the word will be correctly accented as you have marked it, *Gladi'olus*.

For what reason does "D." throw the accent back on the first syllable? (By-the-by, at page 210, he calls it *gläd*, at page 296 he accents it *gläde*.) I infer that this is his rule: all derivatives follow the accent of their respective roots. Let us see. We will suppose he has a seedling *Rose*, the desire of every eye, and he names it "*Desiderium*." Now, this word comes from *dési'dero*, is he prepared to pronounce it *dési-dërium*? or in memory of a friend departed, he calls another "*memoriam*," will he pronounce the word *mem'oriam* because it comes from *më'mor*? Would he say *ex'üerät*, *hab'üerat*, *mü'lleris*? Would not most persons follow the rule given by Edwards, and, in each case, place the accent on the antepenult? Let us bear in mind that the question is not as to the quantity of each syllable in *Gladiolus*, but on which syllable shall the accent fall. My authority has been given, let "D." produce his, and if his prevail, I will cheerfully bow to it, and return to the pronunciation for which I stood corrected twelve years ago, and again say *Gladi'olus*. But the barbaric saddle is put quite on the wrong horse.

As you have some ambitious "*Latiners*" among your young gardeners (page 63), you may not think me out of place if I quote a few more sentences from Edwards' preface on Quantity and Accent. "By Quantity we are to understand the time actually devoted to the enunciation of a syllable—uttered quickly, it is said to be short; slowly, long. By Accent, a peculiar inflexion and stress of voice laid upon some one syllable of a word. In Latin, the accent falls either upon the penult or the antepenult of words: hence it follows that in all words of two syllables the stress must be on the first syllable. It would, no doubt, have been extremely amusing to the ancient Greeks and Romans to hear a word pronounced with the accent on the fifth or sixth syllable from the end, as it sometimes is in English, when in their respective tongues the antepenult, or third syllable from the end, was the very farthest from the terminational syllable that the accent was ever removed."

As I intend not to return to the subject, you might wish to ask me how I would pronounce the word, I say *Glade'olus*, not *Gladeye'-olus*. By this method, whilst the accent is correctly placed, the "i" is not made long in quantity.

I trust that at least Mr. Beaton (Is he an N.B.?) will forgive me for preferring the "ee" to the "eye."—S. D. S.

SELECT ORCHIDACEOUS PLANTS.—The sixth Part of this beautiful serial is now published. It contains *Acrides Williamsii*, *Dendrobium Dalhousieanum*, *Oncidium sarcodes*, and *Cattleya superba*. Four more contrasting plants, yet all lovely, could not be brought together from among the plants of the genus. The plates and the letter-press are all that can be desired.

THE APPLICATION OF GUANO WATER TO HOT-WATER PIPES.

WOULD your correspondent Mr. D. Thomson give more precise information as to the use of guano as recommended by him in his useful and suggestive article on "Insects and the Atmosphere of Hothouses" in your Journal of October 13th? He merely says, "I mixed up a small potful of Peruvian guano and applied it regularly to the pipes, &c." Is the guano to be mixed with water only or with water and soil, and in what proportion, in what quantity, and how often applied?—COUNTRY CURATE.

[In the case of the vinery, to which reference was made in my paper on this subject, the guano was applied at about the rate of 1 lb. of Peruvian guano to four gallons of water. There was no soil used. It was applied regularly for three weeks. This, as stated, was for the destruction of a terrible attack of red spider; but when the object is simply to impart strength to vegetation it is sufficient to colour the water with the guano.

In applying it regularly to our Pine-pits, where there are large old-fashioned pipes having a flat surface, saucers are set on the pipes and the water put into them instead of the pipes. The saucers are filled up with clear water frequently till the guano-charged water previously put into them runs over on to the surface of the pipes, and this is continued till guano is again added to the water in the saucers and the same process continued. In this case 4 ozs. to a gallon of water is perfectly safe.—D. THOMSON.]

FAILURES IN BLOOMING GLADIOLI, LILIUM LANCIFOLIUM, AND AMARYLLIS.

I HAVE to request your advice regarding some bulbs which I have failed in blooming this year. I have not seen in the *Gladioli* here the disease that has been so much complained of elsewhere; but having a number of them in pots I have found that a few of them have entirely rotted, and have left some quite healthy offsets. I have met with the same calamity in several classes of the bulb family. Can there be any fault in the treatment?

I should also like to know what can be done with some expensive *Lancifolium* Lilies and *Amaryllis*, which, though not yet beginning to fade, are yet showing no symptoms of bloom. Should I now let them become dry and go to rest, or, by keeping them moist and warm, can the season be prolonged with them?—A. W., Belfast.

[*Gladioli*.—We suspect the drainage in the bottom of the pots has not been sufficient, or that by worms or some other cause its efficiency has been destroyed, and that, as a consequence, stagnant water about the roots of your *Gladioli* has caused them to decay. The healthy offsets which have been produced are an effort of nature to perpetuate the plants, examples of which are often met with when the parent is from some fatal cause destroyed. It is, however, by offsets or by the production of fresh bulbs at the expense of the parent that the *Gladioli* perpetuates and multiplies itself. When *Gladioli* are grown in pots the drainage should be most carefully and efficiently performed, as all bulbous plants that make this fleshy root are very impatient of stagnant water. The soil in which they should be potted should be rich, but not grossly so, and rather light in texture than otherwise. They require during their growing and blooming season a plentiful supply of water, but they will never withstand with impunity a wet puddley condition of the soil arising from insufficient drainage or any other cause. After they are done blooming the amount of water must be gradually decreased till the soil becomes dry. This is to imitate as nearly as possible the wet and dry seasons to which the plant is exposed in its native habitat.

Lilium lancifolium.—It is presumed that these have shed their leaves by this time. The proper way to manage them after they are done flowering is to gradually withdraw water from the root till by the time they have shed their leaves, the soil in which they are growing becomes comparatively dry, but not mealy dry, so to speak; we have always found the bulbs in a more fresh and healthy condition when just kept a little moist all winter than when allowed to become very dry. They can be wintered anywhere where frost

is merely excluded. The time to shake out the bulbs and start them must be regulated by the time you require them to flower. However, unless your bulbs are strong and healthy, it will be best not to interfere with them till February; then shake them entirely out of the old soil, and repot them in soil consisting of two parts turfy loam, one part leaf mould, and one part well-decayed cowdung, with a sprinkling of sand mixed in along with these proportions. In potting them they may be put into their flowering-pots at once. Presuming that they are moderate-sized bulbs, you may put one in an eight-inch pot. Place the bulb deep in the pot—say 3 inches below the surface of the soil. The principal feeding-roots are thrown out ultimately on the stem between the top of the bulb and the surface of the soil; hence the value of deep potting in this case. Some start them in small pots, and then shift them, potting them deeply when transferred into larger pots. Either way does well enough, but the former is attended with least trouble. If you have a number of bulbs that are likely to flower and you desire large specimens, then you may put six or eight into a 12-inch pot. In the case of bulbs that are small and not likely to flower, by far the best way to get large bulbs quickly is to plant them out in a deeply-trenched, light, rich, loamy soil. Here they increase in size and multiply far better than when confined to pots, and are much less trouble. A greenhouse temperature is sufficient to start them in, and after all danger to the young stems from frost is over, place them in a sheltered but fully exposed position out of doors, and so that worms cannot find their way into the pots.

Amaryllis.—In the absence of more minute information than that which your letter contains it is impossible to say whether you may yet expect them to flower or not. If they have fully expanded their foliage, and have not yet flowered, they will not now flower till they have fully matured their growth and have had a season's rest. If your bulbs are in this stage you must now place them for a time in an intermediate temperature between that of a stove and greenhouse, and let them have as much light as possible, so that the leaves may be kept in vigorous healthy action, for on this depends the quantity of nutritive matter prepared and deposited in the bulb, which is essential to their flowering next season. Give just sufficient water to keep the leaves from drooping, and very little indeed will be required for that. There are a few simple points connected with the culture of the *Amaryllis* which if attended to will be certain to be followed with success. These are, to use for soil a rather adhesive loam that does not become powdery when dry, perfect drainage so that a puddled state of the soil never can take place, no more water should ever be applied than is just sufficient to keep the foliage erect and green when growing, full exposure to all the light possible during the growing season, complete rest by being kept cool and dry after they have matured their growth. By varying the season of growth and rest in different sets of bulbs these may be had in bloom every month in the year; and from their great beauty we are not surprised that they should have taken their name from a nymph of the ancient poets.]

AMMONIACAL GASES IN HOTHOUSES.

In reference to Mr. D. Thomson's article on "Insects and the Atmosphere of Hothouses," eight years ago when apprentice at Whittingham, Haddingtonshire, I, according to directions, had to fill the evaporating-pans, which were cast in the covers of "the rickety old blues," night and morning, in all the houses at work, with diluted liquid manure from the farm; but my master never liked it so strong as to affect the eyes, not even to smart in the nose. Once I remember having slightly overdone it, and next morning a few of the young leaves were black.

In houses heated with pipes, to fill the evaporating-troughs with the manure water, and siphon the latter from the former with a piece of old flannel on to the pipes, gives the desired effect to any extent.—A YOUNG GARDENER.

SALE OF JAPANESE PLANTS.—At the sale of the valuable plants brought by Mr. Robert Fortune from Japan, and which took place at Stevens's Rooms, Covent Garden, on

Wednesday and Thursday last, a sum of between £600 and £700 was realised. Among the lots were included the original imported plants of *Sciadopitys*, *Retinospora*, *Lonicera aureo-reticulata*, variegated *Euryas*, *Euonymus*, *Osmanthus*, &c., as well as of the true *Aucuba japonica*. The latter, from 2 to 3 feet in height, brought from £5 10s. to £9 each; *Euonymus radicans variegatus*, 18s. to £4 4s.; *Sciadopitys verticillata*, £2 10s. to £5; *Osmanthus ilicifolius* and its dwarf variegated form, from 15s. to £2; *Lilium auratum*, £2 4s. to £5 10s.; *Deutzia crenata flore pleno*, £1 5s. to £2; *Hex Fortuni*, 17s. to £1 7s.; *Eurya latifolia variegata*, £1 to £2 12s. 6d.; *Euonymus japonicus variegatus*, 17s. to £1 10s.; *Retinospora pisifera*, 14s. to £1 3s.; *Nageia japonica*, 12s. to £1 3s.; *Taxus Fortuni*, £1 4s. Lots of ten *Pinus densiflora* were sold at 10s. and 11s.; of six *Sciadopitys* at 14s. to 16s.; and larger ones, 6 inches high, at 23s. per pair. Altogether there were 628 lots offered for sale, and realised between £600 and £700.

HARDY AQUATICS.

(Concluded from page 313.)

APONOGETON DISTACHYON and *A. angustifolium* are pretty white-flowering, half-hardy plants, probably quite hardy in the south of England. They grow 6 inches high. They are from the Cape and Southern Africa generally.

SAURURUS (Lizard's-tail).—Very curious plants. *S. ceruus* grows 8 feet high, and is from Virginia; and *S. lucidus* grows 1½ foot high. Both are perennials, and have apetalous flowers in September.

POLYGONUM.—*P. amphibium*, a native plant, has pink flowers, and grows 1 foot high. *P. mite*, from North America, has red blooms. *P. salsuginum* is a pretty species from the Caucasus, with pink flowers. The last two are annuals, growing a foot high. *P. senegalensis* is an annual, from the Senegal, in Guinea. It grows 1½ foot high, and has red flowers in July and August. *P. coccineum*, with scarlet flowers in June and July, growing 1 foot high, is a very pretty plant. From North America, and a perennial.

ELATINE (Waterwort), are minute and curious annual plants. *E. hydropiper* and *E. tripetala* are the only representatives; both are natives of this country, and of Europe generally.

HERPESITIS.—*H. euneifolia* is a very pretty perennial, from North America, with wedge-shaped leaves, and blue flowers in August. *H. amplexicaulis*, *H. rotundifolia*, and *H. micrantha* have blue flowers in July and August. They grow but a few inches high, and are from the swamps of Carolina. The last three are half-hardy.

LIMOSELLA AQUATICA is a pretty little annual with flesh-coloured flowers appearing in July and August.

SIETHORIA EUROPEA is a pretty trailing plant, with yellow flowers in July and August. Useful as well as ornamental for covering rocks in moist shady places, and for that reason I have introduced it. It is not an aquatic.

CARDAMINE (Ladies' Smock).—*C. latifolia*, from Spain, grows 1½ foot high, and has purple flowers from June to August. *C. dentata*, from Russia, has white flowers from April to June. *C. pratensis* (Cuckoo-flower), and *C. p. plena* (double-flowered), are really very pretty perennial plants, growing a foot high, and having purple flowers in April and May. Britain. *C. amara* is also a British species, growing but a few inches high, and has white flowers in April and May. *C. uliginosa*, from the bogs of Tauria, is a minute and very pretty plant, with white flowers in April and May. They are all perennials, and require to be planted at the margin of the water.

SUBULARIA AQUATICA, with awl-shaped leaves, is a curious little annual with white flowers in July. It inhabits the lakes on both sides of the Tweed.

TYPHA (Cat's-tail).—*T. latifolia* grows in wide ditches and stagnant pools of water, is 4 to 6 feet high, and produces a close cylindrical head of brown inflorescence on a cane-like stem. A noble reedy plant, commonly known in the north as Bullrush. *T. minima* grows in marshes, attaining a height of 2 feet. *T. angustifolia* has narrow leaves, and a large, close, cylindrical cluster of catkin-like flower-heads in July; it grows 4 feet high. *T. minima* is a dwarf species, growing but a foot high; from the Swiss lakes. All are

perennials, and well worth cultivating for their reed-like habit. They grow in the water.

CAREX.—*C. Davalliana* and *C. dioica* are curious, dwarf, grass-like plants. *C. pulicaris* and *C. pauciflora* are also curious taller-growing Sedges; and *C. paniculata* attains the height of 3 feet, very commonly having stem-like crowns several inches high, from which the leaves droop gracefully. Sedges are a numerous family. Some of them are highly ornamental on the margin of water, the taller species especially.

LITTORELLA LACUSTRIS has oval leaves, and white flowers from June to August. It is a small, delicate-looking British plant, growing on the margin of sandy pools, and is a perennial.

ZIZANIA.—*Z. aquatica* (Canada Rice), is an annual, strong-growing, reedy plant with green inflorescence from July to September. It grows 6 feet in height. *Z. miliacea* has the habit of Millet, and grows 4 feet high. *Z. fluitans* grows also 4 feet high. All are annuals from North America.

NAJAS MAJOR is another curious annual. Europe generally.

MYRIOPHYLLUM (Water Milfoil).—*M. spicatum* and *M. verticillatum* are pretty native perennials, growing 1 foot high in ditches and ponds. They have respectively red and green flowers in July and August.

CERATOPHYLLUM DEMERSUM and *S. submersum* are perennials and natives, but of no ornament anywhere.

SAGITTARIA (Arrow-head).—Handsome plants, belonging to the natural order Alismaceae. *S. sagittifolia*, with arrow-shaped leaves, grows 2 feet high, and has white flowers from June to August. It is a native species, found in rivers. *S. rigida* grows a foot high. *S. natans* (Floating), and *S. latifolia*, with broad leaves, grow 1 foot high and have white flowers in July and August. They are from North America. *S. falcata*, from Carolina, grows a foot high, and has white flowers in July and August. *S. obtusifolia*, *S. graminea*, *S. heterophylla*, and *S. hastata* have white flowers, and are half-hardy perennials. The first is from China, the others are from North America. There is also *S. obtusa*, another half-hardy perennial from North America.

HYDROCHARIS MORSUS-RANÆ (Frog-bit).—A curious perennial, growing but a few inches high in our ditches. It has roundish leaves and white flowers in June and July. One of the handsomest of the small British aquatics.

STRATIOTES (Water-Soldier).—*S. aloides* has sword-shaped leaves, habit stiff and erect, with white flowers in June and July, growing 2 feet high. England; ditches.

ISOETES LACUSTRIS (Marsh Quillwort), is a curious cryptogamic plant, inhabiting the alpine lakes of Britain.

SALVINIA NATANS, a little floating plant from Italy, and **MARSILEA QUADRIFOLIA**, which is scarcely an inch high, but very curious, are both difficult to keep in a state of cultivation.

LYCOPodium HELVETICUM is an aquatic Club Moss, very curious indeed. It is from Switzerland.

OSMUNDA REGALIS (Royal Fern), is the noblest bog plant we have. It grows in shady boggy places, and does well on the margin of water. It frequently attains the height of a man. *Osmunda* is common throughout Europe.—GEORGE ABBEY.

TODMORDEN BOTANICAL SOCIETY.

October 5th.—the President in the chair. The table was strewn with numerous beautiful and interesting specimens; the following were noticeable amongst phanogams: *Hibiscus Rosa-sinensis* fl. pleno, *Vinca ocellata*, *Urtica biloba*, the marginally-variegated variety of *Serissa fetida*, from Japan, beautifully in bloom, the flowers being of a snowy whiteness, *Peperomia pulchella*, *Cyclamen europæum rubrum*, *Cyperus alternifolius variegatus*, *Rondeletia speciosa major* (a most beautiful orange-and-yellow-flowered stove plant), the curious *Dorstenia contrajerva*, and a fine example of the noble *Tritoma Burchelli*. Why is it that, in gardens, one so rarely meets with this splendid flowering-plant, so effective in summer for purposes of display out of doors, and so interesting in itself?

But at the table of the Botanical Society the *bonnes bouches* are reserved for the cryptogamic botanist. Fine specimens of the Filices named below drew general attention,—viz.,

Nothochlana trichomanoides, the very rare *Mohria achilleæ-folia*, the new *Gymnogramma Laucheana*, *Scelopendrium vulgare marginato-fissum*, *S. v. bimarginato-cordatum*, *S. v. sagittato polyeuspis*, *Athyrium Felix-femina coronans*, *A. F. f. grandiceps*, *Ceterach officinarum crenatum* (County Clare) and *Polypodium vulgare multifforme*, the last named plant having been gathered, in splendid examples, by the Secretary during a recent tour in North Lancashire.

Mr. H. Halstead, of Bacup, exhibited two new varieties of *Lastrea montana*, recently gathered by him in the neighbourhood of Luddenden.

The following communications, from honorary members and others, had been received by one or another of the officers since the last meeting of the Society:—From Dr. O'Brien, of Ennis (Ireland), in regard to the discovery of *Polystichum lonchitis* on limestone rocks in County Clare; from G. Martyn, Esq., Gregans Castle, Ballyvaughan (Ireland), on the pteridology of parts of Clare; from Mr. William Hobson, Philadelphia, U.S.A., giving a list of the North American Filices growing within twenty miles of Philadelphia; from C. J. Ashfield, Esq., of Preston, announcing his discovery, in the fens of Norfolk, of the very rare British flowering plant *Liparis Læselii*; from Mr. J. Sim, of Perth, in regard to British Mosses, &c.

APONOGETON DISTACHYON HARDY— WINTERING CANNA ROOTS.

IN the interesting papers you have lately published on the subject of "Hardy Aquatics," I see no notice of *Aponogeton distachyon*. I am aware that in Loudon's Encyclopædia it is mentioned as a greenhouse aquatic, blooming from May to July; but I have had it for more than ten years in a pond in my garden at Bath, where it generally blooms three times in the year. The blossom I enclose is one of the first specimens of its third blooming in this year, and it will continue to throw up its peculiarly-shaped, ivory-textured, and very fragrant blossoms until the frosts check it. It is planted in not more than 1 foot of water, it seeds freely, and sows itself in various parts of the surrounding pond, the severe winter of 1860-1 not having in the least injured it. I fancy it is not very common, as I searched for it in vain amongst the aquatics at Kew.

Could you give me any hints on the autumn and winter management of *Canna* roots? I have a bed of fine roots raised this year from seed sent me direct from India, and I shall be grieved to lose them now through mismanagement.—E. L. O.

[There are two species, *Aponogeton distachyon* and *A. angustifolium*, both hardy when planted sufficiently deep to be out of the reach of frost. One foot, however, is quite depth enough to plant them below the surface of the water. The flowers are white and very fragrant. Both are from the Cape of Good Hope. They seed freely, and soon fill shallow pools of water with self-sown plants. *A. distachyon* blooms from May to October, and *A. angustifolium* from April to October. I have seen these in no less than six places perfectly hardy, and our correspondent will perceive, on referring to the preceding page, that I have not forgotten them.]

After the first frost take up the *Canna* roots and store them away in sand out of the reach of frost, like *Dahlia* roots. Pot them in February, and bring forward in a gentle heat. Gradually harden-off after growth commences, and plant out in May. Six inches of leaf mould, spread over the roots in a half-decayed state, will usually protect them from frost; but unless your climate be very mild, the plants do not flower so freely as those wintered under cover.—G. ABBEY.]

GRAHAM'S AUTUMN NELIS PEAR.—We have received from Mr. Graham some fruit of this delicious Pear, trees of which are now for sale by Mr. Standish, of Ascot and Bagshot. The fruit is rather larger than the Winter Nelis, and for richness of flavour is not surpassed by any Pear of its season. The tree, which is as yet quite young, bore this year upwards of a bushel of fruit, which was so heavy that the branches required to be supported with stakes.

LIFTING THE ROOTS OF GRAPE VINES.

I HAVE a small house of Muscats, the Grapes in which, during their early growth, are very subject to the spot, and when ripe they rot. I am certain the evil arises from the border, which I intend re-draining and making of a lighter material. I should like to do it now; but the question is, Shall I injure my crop of Grapes, which is just ripe?—*M. W., Burnet.*

[The best time to lift the roots of Vines such as you describe is before the leaves cease their functions and when there is a certainty of the Vines making fresh roots before winter. This is generally in September. We would recommend you, now that the season is so far advanced, to leave them alone till about a month before you intend starting them next spring; and, as soon as you perform the operation, protect the border from cold rains, and if you can place a bed of leaves over them so much the better. The heat will assist root-action. Apart from the consideration of the fruit now on the Vines, which will suffer if the Vines are lifted now, the spring is a better time than winter to carry out your intentions.]

ROOTS AND LEAVES.

Roots in some points correspond with the mouths, and leaves with the stomachs and lungs of animals. Plants, however, differ from animals in having the principles of vitality and reproduction diffused throughout their structure: they can be propagated by several of their parts, whereas animals are solely reproduced by ova or seed. We may take away the limb of an animal in the same way as the arm or branch of a tree, and no fatal result will follow; but destroy or fail to feed the stomach of an animal and its existence terminates. This is equally true of plants in a general sense; but if we destroy the leaves no such immediately fatal results ensue. The plant has in store a quantity of dormant eyes, which are called into action when its existence is threatened. In some plants the powers of reproduction are so great that it requires nothing short of the complete destruction of every part to destroy vitality and prevent reproduction.

Although plants have such extraordinary properties of vitality and reproduction, there are two parts of their structure that must act in unison and be present in them or the subject loses its vitality. The two parts alluded to are the roots, and the stems and leaves of a plant. No plant can exist much less enlarge without them, hence their immense importance in the vegetable economy; but a plant, or some part thereof, may retain its vitality for a definite time without either. True, the leaf of a *Gloxinia* may contain the vitality necessary for the reproduction of the plant from which it is taken; but that cannot be called a plant, it being merely the germ of a plant, for until roots are formed nothing is present that constitutes an organic structure. The leaf, however, imbibes moisture from the atmosphere, and sends down a portion of matter which causes cellular matter to protrude from the bottom of the leaf, forming what is termed by gardeners the callosity, and, through this, ligneous fibre protrudes and appears as roots. Although the leaf has not become a plant as yet, it has, however, an organised system; the roots absorb moisture from the soil along with some of its chemical ingredients held in solution by water. The whole is transmitted upwards into the leaf, where it is exposed to the action of air and light; the crude sap is decomposed, carbon is added, and after it has become elaborated it descends and forms the tuber, or what would in the case of a ligneous plant become wood. Now that the plant has an organic system (for it has such immediately on the protrusion of roots), the removal of the roots causes the leaf to flag, and for a time delays the success of the striking. Presuming, however, that the leaf is again placed in the soil new roots will appear again from its extremity, but no enlargement of the tuber or stem (the roots of *Gloxinias* and *Cyclamens* are simply stems, and not bulbs as in the case of the *Hyalanthus*), takes place until root-action recommences. At this stage remove the leaf, and the equilibrium existing between the root and the leaf is at an end.

The existence of the part intended for a plant is now

dependant on the stage at which the tuber has arrived. If it has attained the state of a bulb the root and leaf will be of no further use to it: therefore, the removal of either does not destroy the vitality of the bulb, although this will not attain the perfection it otherwise would have done had neither of them been removed. If, however, the leaf be removed at an earlier stage, say immediately on the protrusion of roots, the death of the part beneath the soil follows as a necessary consequence. The roots will not absorb nutrition from the soil because the part in which it is to be elaborated is not present; and until there is a digestive system no enlargement of any part takes place, and if there be no eyes or matter to form them the death of the remaining portion is a necessary consequence.

Roots, then, are necessary to the formation of leaves, and leaves must be present or no enlargement of the stem or, the structure of the plant can take place.

I shall not pursue the philosophy of the roots any further, nor that of leaves, beyond giving a faint outline of their uses in the vegetable economy, for that will be found fully treated of in the "Science and Practice of Gardening."

Some years ago I received several Fig trees in pots from a nursery, and found on turning them out in order to repot, that the extremities of the roots were dead. Prior to this I had been led to attach great weight to the preservation of the spongioses, and could only account for their being dead by some injury, as frost or exposure to excessive dryness. Having some dozen plants to pot I found the same decayed state of the spongioses, and I put my Fig trees in their quarters with a presentiment that they would do little good the season following. The same season I took up a Peach tree and found that the greater part of the spongioses were dead, in some cases beyond the axillary fibres, and those that were found alive were situated at a considerable distance from the stem, and evidently were the growing points of the main roots. Those appertaining to the secondary or side branches of the roots were also incapable through decay of collecting nutriment from the soil had the condition of the plant required it. Although careful to retain as much fibres as possible, I found on spreading out the roots that there were not half a dozen fibres that had the extremities fresh or even capable of elongation. Shifting some Lime trees nearer spring, I found the fibres fresh and full of sap, though the extremities had the appearance of having been cut transversely by some sharp instrument, and beyond this point was found the skeleton of about 6 inches of the extremities of the roots. These little matters combined led to my paying more attention to roots than hitherto, and from reading an article in a contemporary, attaching great weight to the importance of preserving the extremities of the roots of deciduous trees in autumn or winter transplantation, I was led to oppose the teaching of the learned dictator in my humble way. The communication I need not say never saw the light of day, but from that time to this I have seen nothing to remove but a great deal to confirm my opinion that the spongioses are renewed annually, or the roots themselves die back for the most part between the fall of the leaf and the flow of the sap in spring. Nine out of every ten deciduous trees and shrubs with which I am acquainted, and I have seen them by tens of thousands in a nursery, have no spongioses ready to collect nutriment from the soil on the return of warmth and increased light.

There are exceptions to this rule, of which the Apricot is one; and I may say that the failure of Apricot trees in orchard-houses is more attributable to a too late top-dressing in autumn than any other cause. The Apricot emits fleshy roots in autumn, which run a long distance without sending out side branches or fibres. They remain active throughout the winter, and a quantity of small fibres are protruded simultaneously with the opening of the Apricot blossom. The Vine is another exception. It, like the Apricot, emits fleshy roots in autumn, which appear to serve no purpose beyond that of extension. Neither is their destruction of any extraordinary moment to the next year's development. Whether the Vine emits those fleshy protrusions to repair the waste that is continually going on by the stems being kept in a dry atmosphere, or for affording the means from which many minor protrusions or fibres can radiate in the succeeding summer is not for me to say, but if they are left alone they often traverse a great distance without sending

out any ramifications during winter; but simultaneously with the expanding of the foliage, all along their length at every inch and even less, a quantity of small fibres appear, and these, unlike the fleshy root itself, do not travel far before they become forked or branched, and then quickly branch again, penetrating through the soil like a piece of fibry network, the end of each fibre absorbing nutriment from the soil with great force. These fibres do not arrest the progress of the fleshy root, but it continues to lengthen, and it takes a direct course unless it comes in contact with a hard substance which it is impossible to penetrate, when it runs along the surface of the obstacle, and when clear of it again continues its journey outwards from the stem and traverses a great distance. I have found them 60 feet from the stem of a Vine.

The fleshy roots, then, are the prolongation of the main roots, and are distinct from the fibres. They do not die annually, nor even at any time unless injured or destroyed by a bad soil. From them secondary roots having the same properties as those from which they take their rise, branch at long or short intervals, and from these fibres are likewise emitted. These fleshy roots are more abundant in rich soil than in poor ground, whilst fibres are more abundant in the latter. In very rich Vine-borders the root-stems seldom emit anything beyond the thick fleshy roots, and the fibres that are sent out by them in turn are of short duration; but they rarely emit any.—G. ABBEY.

(To be continued.)

SOME GARDENS WORTH SEEING.

DERBYSHIRE.

Name.	Proprietor.	Gardener.	Station.
Sudbury Hall	Lord Vernon	Mr. A. Dick	Sudbury.

NORTHAMPTONSHIRE.

Finedon Hall	W. M. Dolben, Esq.	Mr. Archer	Higham Pencers
Moulton Grange	I. Nethercote, Esq.	Mr. Wells	Northampton.
Bulwick Hall	T. Tryon, Esq.	Mr. Kidd	Wansford.

—C. M. MARTIN, Northampton.

[We have omitted our correspondent's remarks because he had entirely lost sight of what we stated when we commenced publishing these lists—viz., that they are only the gardens which those who favour us with the lists consider will gratify if visited. Such lists may be added to by others, but are not open to criticism.—Eds. J. of H.]

YORKSHIRE.

Newton House	Mrs. R. Russell	Mr. Naylor	Leeming Lane
Thorpe Perrow	Mark Milbanke, Esq.	Mr. W. Culverwell	Bedale.
Swinton Park	Admiral Harcourt	Unknown	Bedale.
Brough Hall	Sir W. Lawson, Bart.	Mr. Burrows	Catterick.
Aske Hall	Earl of Zetland	Mr. Miller	Richmond.
Kiplin Hall	Countess of Tyreconnell	Unknown	Scorton.
Wood End	Earl Ca'heart	Mr. Law	Thirsk.
Sedburgh Park	G. B. Gilpin, Esq.	Mr. Duncan	Richmond.
Bolton Hall	Lord Bolton	Mr. Denning	Leyburn.

GARDENERS' BENEFIT SOCIETY.

Much has been said about a Gardeners' Benefit Society being established in various parts of the country. I think that it is an institution very much wanted, but I should like to know if it is to be a society for gardeners alone, or if a man who is both gardener and groom, and gardener and cowman, and he who has a small garden to look after, and clean knives and forks, and make himself generally useful as well, would be admitted into the Society as gardeners, or not admitted at all? I think that this ought to be thought over.

It was stated in your Journal the other week that some gardeners say that they cannot be admitted into the Society without breaking some of the rules, because they have not served a regular apprenticeship. If such is the case it would be a protection society, as well as a benefit society. Why not admit all who get their living by gardening, no matter whether they have been apprenticed or not, so long as they bear a good character, and are in a nobleman's or gentleman's garden as gardeners?—J. F. DAWSON.

[We know of no valid reason why any the classes mentioned by our correspondent should be excluded from participating in the Society's benefits. Certainly we never heard of any intention to confine its membership to gardeners who

have served an apprenticeship. A gentleman is now employed arranging for the formation of the Society, and we hope soon to see it announced publicly.—Eds. J. of H.]

CALCEOLARIA CANARIENSIS.

Will some of your correspondents be kind enough to impart their experience respecting the above-named plant? I was in hopes that Mr. Beaton's verdict would have made its appearance before this, but am afraid that his long illness has prevented him from going on with the trial as he otherwise would have done, and of which he wrote during last season.

I am sorry to say that the plant was anything but satisfactory here, and, so far from being an improvement on *Aurea floribunda*, it was quite the reverse. Perhaps it may be as well to state that we never knew what a failure was with *Aurea*, and during last winter a great many plants stood the weather without any protection whatever, and nothing could possibly look better or bloom more freely than the whole stock up to this present time; whereas *canariensis*, after much attention in watering and cutting off the flower-stalks for some time after they were planted out, has failed to produce anything like a good show of bloom, and the foliage looks almost as yellow as the flowers. But the worst is that, one after another, the plants died off, so that now we have large vacant spots instead of well-filled beds. I do not think it free enough in growth, or capable of standing the different changes of weather sufficiently to become a good general bedder. Nevertheless, I should like to hear from others who have tried it how it turned out with them before I discard it altogether.—JAMES HARRIS, Gardener to Rev. A. Morgan, Mechen Rectory, near Newport, Mon.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE October Meeting of the Entomological Society was held on the 5th inst., the chair being occupied by Francis Pascoe, Esq., V.P., F.L.S., &c.

Mr. W. W. Saunders, F.R.S., gave an account of the ravages committed by the caterpillars of the Dart Moth, *Agrotis segetum*, on his crops of Turnips near Reigate; the insects at first attacking the plant just below the surface of the earth, so that it is impossible to discover the enemy without removing the soil, and the mischief not being manifest by the leaves flagging and turning yellow until considerable damage has been effected. He had not been able to apply any satisfactory remedy, nor did he think those proposed by Mr. Curtis in his work on "Farm Insects" either practicable or available.

Mr. Stainton gave an account of the rare Moth *Anesychia bipunctella* and its transformations. He also exhibited specimens of a gigantic species of Tortricidae (*T. grandævana*), the caterpillars of which, when about to undergo their change to the chrysalis state, form tubular cases of silk with an outer coating of sand on the shores of the Baltic, and after strong gales of wind are left standing upright to the height of 2 or 3 inches.

Professor Westwood gave some further details as to the mode of preparing dried caterpillars by the German entomologists. He also exhibited specimens and drawings of the small stingless honey bee of Australia, first communicated by Major Sabine and more recently by Mr. Woodbury, together with portions of its waxen nest, and living specimens of the larvæ and perfect insects of a new species of Nitidulidæ which feed upon the wax of the nest. He also exhibited some of the curious cases formed by the caterpillars of the *Psyche helicina* of Siebold. These cases are small and spiral, being composed of silk with a fine external coating of particles of earth, so that they resemble minute spiral shells, or still more nearly the excrement of small birds. He also exhibited the cases formed by *Silo pallipes*, a small species of Caddice Fly, being a tube of silk with minute pieces of stone fastened on the outside so as to exactly resemble the finest mosaic work. From one of these tubes he had succeeded in extricating a parasitic Ichneumon, which proved to be the rare and singular *Agriotypus armatus*, which must possess the instinct of descending into the water in order to deposit its eggs in the tube of the

Caddice Fly, on the larvæ of which the Ichneumon larvæ subsist.

Mr. Bates and Mr. Cutter gave an account of the destruction of large quantities of the seeds of different species of Palms collected in Brazil, and sent to this country as articles of horticultural commerce, especially the nuts of *Maximiliana regia*, by the larvæ of several kinds of Bruchidæ of large size, belonging to the genus *Caryoborus*. In some instances the destruction had been so great that nearly the whole cargo had been destroyed, as many as five larvæ being found in a single nut.

Mr. J. Young sent a notice of the annoying habits of the House Ant, which had been found infesting a house in Guildford Street in great numbers. Some years ago the same insect had been brought under the notice of the Society, when it had been found that the most practicable manner of getting rid of the pest was to lay down small pieces of meat in its burrows. These were very soon covered with the ants, which might be easily destroyed by dipping the meat for a few moments in boiling water.

Dr. Baly read a memoir containing descriptions of a con-

siderable number of new species of phytophagous Beetles of different genera, natives of India, Australia, and the islands of the Eastern Archipelago.

Mr. Stainton gave a condensed account of the entomological portion of the proceedings at the recent meeting of German naturalists held at Stettin, under the presidency of Herr Dohrn; when Dr. Loew read a memoir on the European Trypetidæ, illustrated by figures of large size taken by photography. Herr Kraatz communicated a memoir on the European species of *Melolontha*, with the view of proving that many species found in different countries of Europe, hitherto considered as distinct, were only geographical modifications of the well-known Cockchafer *Melolontha vulgaris*. Dr. Suffrian read a notice of fungi parasitic upon insects; Dr. Hartig on a new genus of Aphidæ found at the roots of Fir trees, having the tibiae and tarsi united. An account was also given of the satisfactory results of the Prussian expedition to Japan, with the view to acclimatise the Japanese variety of *Bombyx mori*, the common Silk-worm, which was found to be much hardier than the Chinese variety.

ONCIDIUM SARCODES (FLESH-LIKE ONCID).

Nat. ord., Orchidacææ. Linn., Gynandria Monandria. Syn., *Oncidium Rigbyanum*.

Specific character.—Plant an epiphyte. Pseudo-bulbs something cylindrical, 3 inches long. Leaves 2 or 3 inches on the summit of each pseudo-bulb, erect, lanceolate. Flowers paniculate. Scape 1 foot long. Sepals and petals bright

lemon-yellow, varied in the centre of each, with numerous dark crimson spots. Labellum large, spreading, two-lobed, somewhat curled at the edges, bright yellow, spotted with dark crimson.

THIS ONCID was purchased by Mr. Henderson, of Pine Apple Place, London, at a sale of the nursery stock of the late Mr. Rigby, a plant-grower at Brompton. It was sent through a friend of Mr. Rigby's to Brompton in 1842, and is a native of

Brazil, but by whom it was first discovered, we regret to say is unknown. It flowers freely in March and April in a pot filled with peat, well drained, and placed in a cool part of the house, and requires the same treatment as other Orchids. 24, 4

WORK FOR THE WEEK.

KITCHEN GARDEN.

In this department proceed with such operations as draining where required, laying Box edgings, gravelling walks, and the trenching and surface-stirring of all spare ground. *Broccoli*, the laying down of this useful vegetable should be attended to at this season, and to be effectually done, no part of the stem below the leaves should be left exposed, because the green part of the stem close to the leaves is much more likely to be destroyed than any other part of the plant. Besides this, there are many other things to put in a state of security; a full supply of Endive, Cardoons, Lettuce, Cauliflowers, &c., for winter use, must have protection, and what has been already stored, whether roots or fruits, should be defended from frosty air. Young plants in frames, such as Cauliflowers, Lettuce, &c., require protection, but only against frost and too much humidity: if the temperature be never less than 32°, they should not be shut up at all by day. *Celery*, earth-up while the weather is favourable, if severe frost should set in some long litter should be laid over the most forward crops. Where Carrots, Parsnips, Salsify, and Scorzenera, are liable to injury from grubs, or from a low, damp situation, the sooner they are taken up and stored away the better. The Beetroot to be taken up without being bruised, the tops carefully twisted off above the crown, and to be stored away in any dry place, free from frost, in sand. *Onions*, the autumn-sowing to be hand-weeded, and the ground slightly stirred about them. *Shallots* and *Garlic* may now be planted in light and dry soils, otherwise they had better not be put in till February.

FLOWER GARDEN.

The approach of winter calls for much precaution, as well in defending tender things against its rigour, as in planting bulbs and tubers, and dividing herbaceous plants before hard frost suspends all out-of-door operations. The display of next spring and summer depends greatly on what is already done, or doing, at this season. The present is a most appropriate season for observing the different colours, shades, and tints, that the foliage of trees and shrubs assumes. A pleasing picture could be produced, when planting, by disposing them singly or in groups, either to harmonise or contrast with each other. *Chrysanthemums* against walls, fences, &c., to have their shoots closely tacked in, and mats to be in readiness to protect them from the first sharp frost, which generally lasts only for a few nights. Tree leaves to be collected at every favourable opportunity, and pitted in some convenient place to rot. Leaf mould is an excellent substitute where peat soil is not easily procured, and of great service when mixed with the soil in the flower-beds, and for the culture of plants in pots. Proceed with new arrangements actively, particularly if they involve the removal and planting of trees. Now is the time for planting-out a good stock of spring flowers, especially, if a gay spring garden is required, abundance of early Tulips, and *Crocus* in variety. Do not forget hardy Cyclamens, these planted near the edges of borders will have a fine effect. *Hepaticas*, too, should be remembered; the colours, red, white, and blue, form a pleasing variety, and when they are well established they flower most abundantly. Snowdrops, Winter Aconites, and Dog's-tooth Violets, play important parts in early spring, the bloom of these comes sometimes through the snow, reminding us that the spring is returning. Standard Roses to be gone over, and all the long shoots to be shortened, reserving the general pruning to the spring. The roots of Dahlias to be allowed to remain in the ground as long as they are free from danger. Polyanthus to be examined, and soil put to the roots which are emitted from the collar; seedlings to be gone over and fastened, for when small the large earthworm often pulls them up. Pansies to be divided and planted out for next season's bloom in richly-prepared ground. The beds for Ranunculuses to be ridged up. The sooner the Tulips are planted the better, for if planting is deferred till the bulb begins to elongate the leaf-spike the roots are injured.

FRUIT GARDEN.

The planting of fruit trees, either in the open quarters or against walls, may be commenced at once. In preparing new soil for planting fruit trees, endeavour to keep it as dry as possible, and choose a dry day for planting that the soil

may be in a favourable state to facilitate the growth of fresh roots during the autumn. The present is also the most favourable time for relifting and root-pruning such trees as are too luxuriant and require checking to induce a fruitful habit. It is preferable to lift the trees entirely, unless they are very large, to cutting off the roots as they stand. Most wall trees would be more fruitful were their roots confined to borders of very limited extent, compared with what is generally the case, and by which the balance between the roots and branches would be adjusted without the trouble and expense of lifting and root-pruning.

GREENHOUSE AND CONSERVATORY.

The period has now arrived in which the increasing scarcity of flowers in the beds and borders should be compensated for by those conservatory flowers peculiar to winter, and by retarded summer things—such as *Euphorbia jacquiniiflora*, *Gesnera zebrina*, *Achimenes picta*, *Gesnera oblongata*, *Linum trigynum*, *Plumbago rosea*, *Begonias*, &c., all of which should have a temperature of 60° by day, rising to 80° in sunshine, and sinking to 50° at night. The *Chrysanthemums* and *Veronicas*, with Scarlet *Geraniums*, *Heliotropes*, *Salvias*, &c., are now interesting and useful flowers. A little gentle forcing will bring the different varieties of *Epiphyllum truncatum* in bloom; and with the addition of late *Fuchsias*, *Pancratiums*, *Amaryllis*, *Mignonette*, *Neapolitan Violets*, &c., a tolerably gay appearance may be maintained until the time when forced plants will be more generally available. Some of the most useful plants during winter and spring when subjected to gentle forcing are the different kinds of *Rhododendrons*, Belgian *Azaleas*, *Kalmias*, &c. As these have now perfected their buds, plants well furnished with buds can easily be selected for the purpose. When selected, to be potted in peat in as small pots as the roots can be put into; to be then watered, and placed in a pit or vinery, to be brought forward as required, beginning with a gentle moist heat, and increasing it as they progress towards blooming.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Laid down *Broccoli*, taking out a spit or two of soil on the north side of the stems, pressing the stem down and covering with spits of earth from the south side, so as merely to leave the head of the plant exposed and that facing the north, which will prevent the flower-head within being acted upon by a bright sun immediately after a sharp frost. The keeping the head all the nearer to the ground affords an opportunity for placing a little clean litter over it, if the frost should be severe. Did much the same with a lot of Cauliflowers, but will most likely put some under protection, as after all there is scarcely any *Broccoli* that eats so sweet in winter as Cauliflower. We have sometimes kept it very well by taking up the stems of the plants when the heads were a little more than half-grown—that is, we cut the plants over just above the roots, removed all the leaves except a few small ones round the head, made the stems firm in damp soil, as thick as the heads would let them stand, in a dark shed, then put 3 or 4 inches of dry sand over the moist earth, and gave air except when frosty. The last-used stems would often have roots protruding from the sand and ground. When they had been in such a position some months, the heads that were at all advanced would be apt to open and spread a little; but this could be neutralised by placing them in cold water for a few hours before taking them to the kitchen. Even if a little open they make a nice dish when cut into bits, so as to resemble Sprouting White *Broccoli*; and if used before much frost has partly acted on the latter, and made it sweeter and more tender, the Cauliflower will generally be the better of the two. Planted out some Cauliflowers under glasses. Potted a few to be kept under protection. Pricked out more in readiness; also pricked out Lettuces for spring use, and will lift some to put in a frame for winter use. Took up most of the Carrots, the weather being fine and mild, and the sun very strong for the season.

Cleared out most of the Cucumber-beds, as we do not care about them now. Now is a ticklish time for those plants that are to bear all the winter. In such weather as

this they will bear very freely and show freely; but prudence would say, Allow hardly any fruit to swell as yet, for the more that do so the more exhausted will the plants be about the new year, when most probably they will be most required. A country and a metropolitan demand are also very different things. Amongst fashionable people Cucumbers may be often more in demand in the country in the winter than at any other time; and if wanted for home supply at that time they must be had, whatever the expense for fuel or heating material. It would be next to folly to grow at that season for the London market, as Cucumbers only come to be valuable when the parties are given in town after the assembling of Parliament—at least that used to be the case when we lived in London; and that is the answer to a correspondent who wished to supply the London market with Cucumbers in winter and lived 150 miles distant. We have no data by which to judge of the consumption of Cucumbers in winter in the metropolis; but judging from the price at which they then sell, and the high price in February, March, and April, we come to the conclusion that there must be only a limited demand in winter.

The fine sunny days that have taken place have swelled our late Dwarf Kidney Beans wonderfully, and there is now abundance under the protection of some old sashes and frigid domes, from seeds sown in the open ground. Cleared away a portion of the leaves from Sea-kale, to get it to rest more quickly, and moved down part of Asparagus that was getting brown. Artichokes (Globe) in over-stiff soil are still bearing freely, and before much frost comes we will put litter round the stems to make all safe. Several times during the season we have tasted these rough-looking customers and cooked in different ways, and the decision to which we came was that, though very nice, they were a good deal like flint soup that was none the worse for a little meat, rich gravies, and the best of spices. However, the Artichoke is more than ever becoming a fashionable dish, cooked in various ways; and if the gardener wishes to be sure, he had better protect his plants if not with litter, which we think advisable, at least by moving the surface of the soil and throwing some spadefuls of earth, in a crumbly state, round the stems. If the ground in which a plantation is to be made (and now is a good time, and the very moving will deprive the frost of its power), is well trenched and stagnant water prevented, the yield in summer will be greatly increased by giving abundance of manure water. When so treated the fruiting stems branch out with young fruit amazingly. We have seen recommendations to cut down the stems when the first heads are removed; but this we consider wasteful practice, as, with due nourishment, plenty of heads will come from every joint on the stems. Jerusalem Artichokes may either be taken up or left in the ground. We never yet knew them to be injured by frost. Now would be a good time to make fresh plantations in rows 1 yard apart, and 1 foot apart in the rows. We look upon them as most valuable as covers for pheasants. The heads make good cover, and the roots are dug up by the birds and relished in winter. The Mushroom spawn out of doors, covered with litter, is doing well, and will want moving in order to take out what is done and leave what is imperfectly done a little longer. Full details of making, &c., were lately given. The crops in the open shed are still good, and the spawn is running nicely in the first piece in the Mushroom-house, showing little bits like pin-heads. As we have put a lot of manure in the house for successions in winter, and the weather is so warm, the house at present is left open day and night. Our house is a very simple one. A bed on each side on the ground floor, or below the ground level, and a shallow bed on each side above. These make altogether some seven or eight successions. The upper shelves are generally filled first, and then the beds below them assist them with warmth before they are spawned. In the second and third succession there was about one quarter of lumpy friable loam incorporated with the droppings and rough litter, and when well beaten and spawned a thin casing of sheep-droppings was placed on the surface. The third piece is not yet soiled, but will be done in a few days. We find the small-bit system the best when manure is so scarce as with us.

FRUIT GARDEN.

Here the work has chiefly been confined to sweeping the

leaves from Cherries, Apricots, Figs, and Peaches, pruning roughly all trees on walls and bushes, as Pears, Apples, Currants, &c., finishing clearing Strawberry-beds, making preparations for planting as previously reported, giving plenty of air in fine days to late Grapes and a little at all times. Gathering the last of the fruit and looking after that in the fruit-room, and we are sorry to say that Pears are ripening too fast, and not keeping so well as we expected. Vines commenced forcing must go on slowly. Now is the best time to replant or lift the roots of fruit trees that are too luxuriant to be fruitful. Early Vines that had shanked fruit from deep borders should now have their roots raised nearer the surface into fresh soil and drainage be attended to. Figs outside will soon want a little protection. Routine much the same as previous weeks.

ORNAMENTAL GARDENING.

The flower garden would yet be beautiful but for the leaves, which no cleaning will prevent being spread over the lawn. There are beds of Excellence Geraniums as fine as ever a bed could be in August; huge rows of scarlet *Salvia fulgens*, some 3½ feet in height, and rather more across—dense masses of scarlet, than which scarcely anything can be more showy after August, but the tree leaves, yellow and all colours that strew the ground earlier this season than usual, spoil all the charm by their reminders of desolation and decay. We have as yet only taken up a few things, but will take up a few of the best variegated Geraniums, &c., without much delay. A few particular ones we will crum singly into 60-sized pots; but the great majority we save will be taken up, all the leaves removed that are larger than a threepenny-bit, and then we will stuff them as thickly as they can stand, like faggots, either in boxes or large pots. We rather prefer young plants to these, unless when the pyramiding of beds is resorted to. The only thing we have cleared off are several large groups of Hollyhocks. We have cut them down about 6 inches from the ground, and if we find time we will daub the cut parts with a little tar, to prevent the water entering and resting there, and so injuring the roots. Of stems we had several earldoms, and we need to char them, but as at present we are scarce of fermenting material (and what there was of it was chiefly short grass, a few leaves from sweepings of the pleasure grounds, and a little litter from whence the horse-droppings had been removed, for Mushrooms, which altogether would have heated too violently like a puff, and then cooled as rapidly), these Hollyhock-stems were cut with a bill over a block into lengths of about 9 inches, and well mixed with the short grass, &c., and the whole will make an excellent heap of fermenting matter, which will retain heat for a long time. Many things taken up will be the better of a little fermenting matter, to set the roots going. Some Scarlet and other Geraniums taken up are thus helped. All the earth is shaken from the roots, the roots trimmed a little if long and straggling, and then squeezed into a small pot, all the leaves bigger than a sixpence being picked off. The soil must be neither wet nor dry, but dampish, no water given, but the tops dewed with water in a sunny day, the pots plunged into a little heat, and air left on, except when frost comes. Such plants will generally be well rooted in a fortnight, and then may have even more air. Even those placed in the faggot style in bundles would be all the better of a little heat at the roots to encourage the making of new roots before winter. Unless very scarce and valued kinds of *Calceolarias*, it is of little use taking up the plants, we would far prefer taking cuttings of every little bit, and placing them in a cold pit or frame. Such old plants, however, are useful for cuttings in spring; but why not make them now, when the cuttings take up no more room than the plants, if so much, and hardly one will fail if time is given them? This last is the whole secret. A *Calceolaria* cutting will need as many weeks to strike now in a cold place, as it would need days in spring with a little bottom heat. A little bottom heat is all well enough in spring, but if much or any is given now, its tendency will be to enervate the constitution of the future plant, and those plants struck cool in autumn will be hardier, and bear more cold, and bloom earlier than those struck in spring, because they may be planted out much earlier. Spring-struck *Calceolarias* are best for autumn blooming.

As a proof of the mildness of the autumn, the *Calceolaria amplexicaulis* is the finest in bloom, as fine nearly as in

summer, whilst the rains have injured the others very much. This is the tenderest bedding *Calceolaria* we have met with. In some sunny days we just dusted the *Calceolaria* cuttings with a slight skiff from the syringe, making a quart of water, in the form more of mist than syringing, go a great way. In one very sunny forenoon, as Thursday, we gave a slight shade for a few hours. One rule is, to give no shade, if a cutting will stand light without flinching; but it is a good plan to prevent the leaves flagging, whatever plan be used. The error generally committed, is to leave shading longer on than it is required, and that tends to draw the cuttings upwards, and make them weak instead of encouraging them to root downwards.

Reotted a lot of *Pelargoniums* that were cut down late, and had broken nicely, shaking away the most of the earth, trimming the roots a little, and reotting in fresh soil, and into the same-sized, or smaller pots. Proceeded with potting other things as we could get at them, as *Cinerarias*, *Primulas*, &c., and gave the latter more room, as they were so thick as to lose a few of the lower leaves. Would pot some stove plants, but have not as yet a place for them.

We may here remark how circumstances frequently alter cases and the treatment to be adopted. A friend of ours generally beats us in beds of *Scarlet Geraniums* early in the season. We as regularly beat him later in the summer and autumn; in fact in the late autumn he will tell you he has no beds. The reasons are quite on the surface. We can as yet keep no reserve ground for stock, and until late in autumn we are chary in taking even cuttings from our beds so as to mar the outline, and this we wish to keep until the leaves will spoil the lawn do what we will. October then is pretty well ended before we take up any of the finer plants we wish to keep, and frequently in fine autumns it is November. Now our friend's employers leave him in August. A ton or two of pots is no object; and no sooner are they gone than smack goes the knife in the beds for large cuttings, and ere long lots of *Scarlet Geraniums* are taken up, potted, and put in the open air to grow, root, and be hardened before the end of autumn, and to be wintered so as to be turned out large plants by the 20th of May. We could not house enough of these large plants if we had them, and we could not get them at present if we wished it, without injuring the appearance of the grounds when visitors are the most numerous. Those situated like our friend may plant their beds early with bulbs after giving them every necessary preparation. Those who wish bulbs to follow after such late-kept flower-beds should plant the bulbs, as previously directed, as soon as possible in a temporary border in plenty of rough leaf mould, and lift with balls and plant when the beds are ready.—R. F.

ROSE REINE DE LA PAPE.—M. Eugène Verdier gives me the following reason of this name. There is in the neighbourhood of Lyons a little hamlet named La Pape. In this village M. le Maréchal Canrobert possesses a beautiful property, and M. Guillot desired to dedicate his Rose to Madame Canrobert; but perceiving that he had been forestalled, and that another Rose of M. Liabaud's bore this name, he decided to give it the name of "Reine de la Pape" in honour of M. Canrobert, but this fact unfortunately no one knows.

COVENT GARDEN MARKET.—Oct. 24.

But little change has taken place in the supplies both from home and abroad, which still continue amply sufficient for the demand, and the prices quoted are nearly the same as those of the two previous weeks. Fruit of all kinds, both hot-house and out-doors, is plentiful. Of Apples there is an abundance from the continent and the Channel Islands. Filberts are rather more scarce, but the prices remain the same. The vegetable market is well stocked, and some *Kidney Beans* are still to be had. Cut flowers mainly consist of *Orchids*, *Roses*, *Pelargoniums*, some *Camellias*, *Verbenas*, *Stocks*, *Dahlias*, *Ageratums*, *Violets*, and *Mignonette*.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

RIPENING GRAPES IN GREENHOUSE (A. B.).—No periodical makes greater efforts or incurs more expense than we do to give full and accurate answers to questions; but, if we remember right, though you forget, you wrote to us under the signature "W. R. J.," and we replied at page 238, giving some general suggestions, but adding that to answer all your questions would fill an entire Number of our Journal. If you will ask two or three questions on points in which you are still in doubt we shall readily return the best information we can obtain.

GLOXINIAS—TEMPERATURE AND VENTILATION OF PLANT STOVE (A Suffolk Subscriber).—If you wish the *Gloxinias* to flower next summer or early in autumn, the sooner their growing season is brought to a close now the better by drying them off gradually. If you do not mind their being late next season again you may keep those yet to flower in a dry stove heat and they will probably flower yet. As the bulbs become stouter you may expect larger blooms, all other things being equal. Keep the temperature of your little stove for tender Ferns, Begonias, &c., at 60° at night, and give air by day as soon as the heat rises to 68° or 70°; but do not open the ventilator and window in front both at the same time, especially on windy days, or you will create a cold draught, which such plants do not like. SIXTY degrees with fire heat is heat sufficient, and during severe frosts 55° is preferable to a high temperature from an over-heated flue.

PROTECTING CAMELLIA BLOOMS FROM WET—GRAFFS DAMPING OR MILDEWING (S. W. C.).—You may erect a temporary framework over your *Camellias* and cover it with calico steeped in oil. This will protect from wet and admit a good deal of light at the same time. It will be impossible for you to keep *Grapes* free from damping and mildew after this season in your vinery without any means for artificial heat. The fire in the adjoining house and leaving the door open will not be sufficient. It takes good management to keep *Hamburgh Grapes* in winter, even with a flue or hot-water pipes. Why not beat your horse? You will then obtain better *Grapes* and be able to keep them. The sooner *Hyalums* are potted now the better, especially if to be forced into flower early in spring. But you may leave them unpotted for two months yet and still get them to flower; but it is much better to pot at the earliest opportunity after this date.

PERPLE KING VERBENA CUTTINGS (E. B.).—From the appearance of the leaves you have sent there is no doubt you have a severe attack of mildew. With the management ordinarily pursued in the autumn propagation of *Verbenas*, this variety is almost invariably attacked with mildew more or less. Try what the effects of keeping them rather dry at the root and dusting them over with flowers of sulphur will be. This is your best remedy. It is now too late to strike cuttings of this sort to have any prospect of their being of much use to you. It is not too late, however, to lift some of your stubby plants and pot them in well-drained pots, using light rich soil and placing them in a cold but not damp frame. If you can lift with little bulbs of earth all the better. In striking it another year try it in a cold frame and begin early in August, and after the cuttings are rooted prick them off into light but rich soil in well-drained pans or eight-inch pots, and you will find mildew will not be so troublesome as when they are struck in hotbeds.

ROSES FOR PEGGING-DOWN IN A BED (M. & L.).—Most, if not all, the *Hybrid Perpetuals* do well this way, and the *Moss* and *Gallicas* particularly well, while the *China* and *Tea* do not answer when pegged-down, as the shoot often ceases growing after being thus laid down, and the plant supplies its place by pushing up fresh shoots from the collar. It is needless to mention varieties, as all the *Hybrid Perpetuals*, excepting those which strongly partake of the *Tea* or *China* origin, do well so treated.

MOSS ON A LAWN (M., Cliff House).—During the months of February or March scratch as much of the moss off the lawn as you can with a garden rake or light close-toothed harrow, carrying the rakings away. Then sift some good dry mould through a three-quarter-inch sieve, and mix up some *Grass* and *White Clover* seeds with the mould so sifted, give the ground a good sprinkling with it, not so much as to kill the *Grass* plants left on the lawn, but enough to partly destroy the moss and lay a foundation for a fresh growth of *Grasses*. The addition of a little soil to the mixture will, perhaps, prevent the small birds destroying the *Grass* seeds. When the growing season sets in your lawn will appear like a closely-sown corn field, and will waft frequent rollings to get a good bottom. In general a little moss on a lawn is advantageous, and in winter is preferable to the multitude of worm casts a turf on richer ground is often infested with.

STORING AWAY ACHIMENES (*A Country Curate*).—Allow them to remain in the pots they have been grown in, which may be placed in any dry place free from frost until the time for starting them again. This is better than keeping the bulbs in a drawer after shaking the earth from them.

KITCHEN GARDEN INFESTED WITH SLUGS (*Idem*).—As you say you have used lime and soot very freely with little benefit, a slight dressing of salt may be used, or an application of gas water may be of service, or, better still, burning or charring the surface will destroy the depredators. A very sharp winter is, however, a partial remedy, and if the ground were once or twice turned over during the prevalence of frost, it would tend to thin these pests. At the same time search out for them in all their haunts, as Box-edges and all other permanent plants afford them shelter.

WEED ON GRAVEL WALKS (*W. J.*).—Most likely the weed you complain of is *Sagina procumbens*, which is very like *Spergula pilifera*. Shady walks are sometimes troubled with it, but as you say your edgings are of Box, it is not prudent to use salt freely. A careful application of hot water might be of service, as that would kill the surface weed and would be so much cooled ere it reached the roots of the Box as not to be likely to do them much harm. If the walk is becoming discoloured and dirty, breaking it up and turning it will be of great service, and a fresh surface will be exposed which will be less likely to be infested with weeds for a time. Of course, a good rolling will be necessary at the time of turning the walk.

ANNOTT STOVE BOILER (*J. H. S.*).—Your letter was not prepaid. Upon the receipt of two postage stamps your queries will be answered.

NAMING PLANTS (*Alumnus*).—The best work to aid you is London's "Encyclopædia of Plants."

ALOCASIA LOWII (*J. G. Sim*).—Your question was answered last week. We cannot understand your question about *Cerastium tomentosum*.

BRITISH FUNGI (*Oederdesel*).—Dr. Badham's book is a good authority, and illustrated with coloured plates. We are making arrangements for publishing a series of cuts with descriptions in this Journal.

TRANSPLANTING COMMON FURZE (*Half-pay*).—This is far from being a good plant to transplant, as we have known more than one case like yours when the plants all died or only a small fraction of them grew. The best way is to dig the ground and sow the seed where it is to be grown, or if you did try a few plants let them be very young, sowing some seeds beside them as well.

FAST-GROWING HEDGE (*Idem*).—Nothing grows faster than Privet, and if mixed with Quickset, which maintains a greater amount of rigidity, it makes a tolerable good fence, and will grow in any situation.

HARDY PEACHES AND NECTARINES FOR A SOUTH WALL (*Idem*).—The Bathington, Royal George, and Noblesse are good Peaches, and the Late Admirable a useful one in the autumn. The Elruce, Newington, and Red Roman are good Nectarines, and will generally succeed against a south wall. You will, however, find more information on fruit-growing in the "Fruit Gardening for the Many" published at our office, which would be forwarded to you for six postage stamps.

GLASS FOR PITS (*Haildon*).—Hartley's rough plate is the best of all glass for horticultural purposes. It prevents scorching, does not obstruct light nor heat; but for ordinary garden purposes we prefer twenty-one-ounce sheet of good quality to any other. Fluted glass is often so bad in quality that it scorches all beneath it, but when the quality is good it is as good, but no better than twenty-one-ounce sheet glass, though one is double the price of the other.

CAMELLIA BLOOMS DROPPING OFF (*A. B.*).—Sometimes from excessive moisture, or extreme dryness of the soil in which they grow; at other times for want of sufficient heat and light. Sour soil occasioned by imperfect drainage will produce the same result. We rather imagine you have neglected to water your plants in summer, which would cause the buds to lose the tissue of their parts, and now that the sap is impelled into them the buds are thrown off, because their structure cannot admit the sap. Had the plants been duly supplied with water the buds would have been kept fresh and plump, and that is what is wanted. Too much water gorges the buds with crude sap, and that will cause them to be thrown off; the flower-buds being fed and formed by the descending sap after it has been elaborated by the leaves. Too much water and a too dry soil are studiously to be avoided in Camellia culture, the soil at all times being kept neither very wet nor dry, but healthfully moist. Perfect drainage and the avoiding of sudden checks, as keeping the air very dry or very moist, much ventilation at one time and none at another, watering with tepid water one day and cold a few days after, and extremes of heat and cold, are all baneful to the Camellia's expanding or retaining its buds.

SCALE ON AZALEAS (*Idem*).—You do not say which scale it is. Correspondents would materially assist us and get a more specific reply to their communications by giving full particulars on the question asked. If it be brown scale syringe the plants with water heated to 140°, laying the pot and the plant on its side so that the water does not reach the roots. Turn the plant and syringe the plant on all sides. Then whilst the stems are wet rub them with the fingers, and when that is done syringe them with the water as before. Repeat the dose if the first is not sufficient, and if the stems are much infested brush them with fish-liver compound at the rate of 8 ozs. to the gallon of water heated to 140°. Soft soap at the same rate is equally efficacious. If it is the white scale brush the parts infested with a solution of camphor four ounces, spirits of turpentine one gill (half a pint), soft water a pint, Scotch snuff a quarter of a pound, and half a pound flowers of sulphur. This will kill mealy bug as well as white scale, but it is not safe to apply it to the leaves. If they are much infested, pick off those infested, but do not rob the plants of too many leaves, and place the plants in a dung-frame prior to its being earthed for Cucumbers, taking care that the steam is not too rank. If the steam does not cause the eyes to water it is not too rank. In case of your having no such convenience as a dung-pit nor place to make one, drench the leaves affected with gum arabic, four ounces being dissolved in a pint of soft water. A few days afterwards wash the gum off. The gum kills the insects because it prevents their respiration.

SOIL FOR PEACH TREES IN POTS (*Dorset*).—It is not impossible that Peach trees may grow as you were told, in chalk and clayey gravel pounded-up together; but we would recommend in preference, strong clayey loam as the most likely to produce satisfactory results.

WINTERING GERANIUMS IN A ROOM (*An Old Subscriber, Dublin*).—A full answer next week.

ROSES FOR POT CULTURE (*J. R. M. C.*).—You will find the following kinds answer very well for the above purpose:—Anna Alexieff, Baronne Prevost, Baronne Haliez, Cardinal Patrizzi, Caroline de Sansal, Charles Lefebvre, Comte de Nanteuil, Compe d'Hébé, Duchess of Sutherland, Eugène Appert, Géant des Batailles, Général Jacqueminot, Jules Margottin, La Reine, Léon des Combats, Madame Rivers, Prince Léon, Sénateur Vaisse, Souvenir de la Reine de l'Angleterre, and William Griffiths. The same class will answer very well also as standards, adding a few more perhaps with a greater mixture of the Tea and China breeds in their strain, as Gloire de Dijon, Enfant de Lyon, Comte de Paris, and several others, omitting, however, many of this class if the situation be an unfavourable one.

FERTUOUS GRANDE LEAF DECAYING (*H. B.*).—We see nothing wrong with the leaf, further than that it seems to be discoloured by water dripping or standing continually upon it.

GERANIUM CUTTINGS IN SMALL POTS (*Cas*).—For the sake of economising room we should keep the plants in the pots until the beginning of March next year, when we would pot them singly into 48-sized pots. If you could spare the space they would occupy, they would make better plants by being potted into small pots now, and shifted into larger in the spring. They will keep quite as well in small pots as if you potted them into larger. All that is wanted is to keep them safely through the winter, giving nothing in the shape of heat beyond that necessary to secure their safety during the winter, or increased pot-room, until growth commences in the spring.

WINTERING CALCCEOLARIAS AND GERANIUMS (*Idem*).—Geraniums in a cellar must have the leaves removed, otherwise they damp the stems and cause their decay. Calcceolarias need all the old growths to be removed, those that come from the neck of the plants only being preserved. They require light, but Geraniums do quite as well in the dark.

RASPBERRIES ON A LIGHT SOIL (*A Constant Reader*).—What you have done ought to have made your Raspberries very vigorous but not fruitful, for what you have done this year will not be apparent in the fruit until next. We should manure heavily, doing nothing but merely pointing it in, for digging would only injure the roots, and make the soil lighter and more open, the last causing too quick evaporation of the moisture from the soil. When they flower water freely, and when that is past, give a drenching twice a week with weak liquid manure. This, we think, with not allowing the canes to grow too near together, nor too many from a stool, will give you a fair amount of Raspberries another year. The kind of Raspberry may have something to do with their unproductiveness. The Red Antwerp does well on light soils.

HORSE-RADISH CULTURE (*Idem*).—Horseradish should make first-class roots in three years after planting. It is a good plan to make a bed every year, no matter how small, and thus secure a bed three years old for one year's supply, so that four beds would be wanted. After three years it becomes woody and loses its pungency.

ANTS INVADING WALL FRUIT (*Idem*).—Dip some slater's laths in gas-tar and place these close to the wall at its bottom. Ants cannot cross this. The surest plan, however, is to kill them ere the fruit is ripe. Use arsenic and sugar in equal parts with sufficient water to make them of the consistency of cream when mixed. This will destroy them, but care must be taken to prevent other animals from partaking of it. Lime water will make them shift their quarters if it be poured into the nests, and so will guano. Boiling water poured into the nest kills all it touches, and ammoniacal liquor from the gasworks, diluted with four times its volume of water, will expel ants from their haunts if it does not kill them.

MILDEW ON VINES (*Signal*).—We thought the destruction brought upon your Vines was by burning the sulphur. Putting a pan of water near the burning sulphur would not have saved the Vines. Sulphur must never be burned where there is a plant with a leaf or unripened shoot upon it. If you treat the Vines as we directed in our last Journal, we think you will get rid of the pest. Any of the advertisers of hot-water pipes in our Journal would serve you well. Write and ask them about what you require.

HEDGE UNDER LARGE YEW TREE (*Dorset*).—There could scarcely be a more difficult position in which to get a hedge to grow and last for a length of time than that which you describe. Both the roots and the shade and drip of such old Yews are most formidable enemies to anything that you could plant, while the trenching that would be necessary within 5 or 6 feet of the trunk of the tree could not fail to be injurious to it. Your only chance is to plant something already a good size, such as Holly or tree Box, which will remove well at the height of 4 to 5 feet. We have lately been teased with a hedge under a lot of large Yews dying out, and the only way we have been able to establish a living fence is by erecting a paling and then covering it with Ivy, which thrives better in the shade and drip and among the roots of other trees than anything else we know. If such a contrivance be considered too expensive, you might try Hollies of a good size; but we do not think they will do much good.

IODINE AND STARCH (*H. H.*).—In what part of England can that chemist live who does not know what iodine is? He certainly cannot have read any book on chemistry published later than when acetate of lead was called Saccharum Saturni. You can obtain iodine of any London chemist. It is a greyish-black substance obtained from the ashes of marine plants, and when combined with starch gives it a fine blue colour. Its compounds are extensively used in medicine. We cannot tell you any more about the proceedings of M. Commandeur, for we published all the information we have. We should mix half a pound of starch into a paste with water, and add half a drachm of iodine in powder, mix the whole thoroughly, and put the mixture in pots under a cover in places where the slugs frequent.

HYBRID PERPETUAL AND BOURBON ROSES NOT FLOWERING (*A Reader*).—We suspect the bed of Roses to which you refer must have stagnant water about it. The phloëtic mildewed growth which you describe is indicative of such a state of things. If you find on examination that the soil is wet and soured, your best way will be to lift the Roses, renovate the soil, drain the bed thoroughly, and plant them again. Roses like a stiff soil, but will not thrive in any soil where there is stagnant water about their roots.

PROPAGATING CLEMATISES (*Idem*).—The greater number of the hardy Clematise ripen their seed in England, and are easily propagated by them. They should be sown as soon as gathered, and some will come up the following spring, and some will be in the ground twelve months before they germinate. They are easily propagated from layers. They like a dry calcareous soil.

OSMUNDA REGALIS.—This magnificent Fern, once very abundant in Chevington Wood, is now extinct in Northumberland, from destroying this natural forest and draining. A poor amateur would feel obliged by any of your readers, who may find this plant in their locality, sending a frond bearing seed. Address, "Mr. Frond, Post Office, Morpeth."

WINTERING GERANIUMS IN A CELLAR (De Foix).—Strip every leaf off from the Geraniums, and then tie them together in bunches by the roots, three or four plants in a bunch, and hang them up in your cellar. Keep the cellar as free from damp as possible by occasional ventilation. The temperature in which Geraniums keep best in such situations is about 40°. You may also try some of them with their roots put into dry earth in boxes. But in either case strip them of all their leaves and let them be housed before their points are touched with frost. Look over them at intervals through the winter, and remove all signs of damping or decaying shoots, and dust the wounds over with hot lime.

NAMES OF FRUIT (G. M. C., Hatfield).—Your Apple is the French Crab. (*W. Armstrong*).—1, Autumn Colmar; 2, Beurré d'Arenberg; 3, Marie Louise; 4, Marie Louise; 5, not known; 6, Napoleon; 7, Winter Nelis; 8, Beurré Bosc. (*G. F. & S. H.*).—Your Pear is Figue de Naples. (*T. G. H.*).—1, Old English Codlin, of which we should like to have a few gratts; 2, Golden Noble; 3, not known. (*E. C. W.*).—PEARS.—1, Beurré d'Anjou; 2, not known; 3, Passe Colmar; 4, not known; 5, Downton; 6, Triomphe de Jodoigne; 7, Duchesse d'Angoulême; 8, Beurré Diel; 9, White Doyenné; 10, Thompson's; 11, Swan's Egg. **APPLES.**—1, Blenheim Pippin; 2, La Fameuse; 3, Scarlet Nonpareil.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (*W. W.*).—1, Escallonia rubra; 2, Lonicera flexuosa; 3, some Hakea or Leopogon apparently. Brown's "Forester," last edition, will give you full instructions for managing woods and plantations. (*W. R.*).—Your Passion-Flower seems to be Passiflora ligularis. Your seedling Geranium, as a flower, is inferior to many; of course we cannot say anything about its merits for bedding, as that depends upon its habit. (*M. D.*).—A Solidago, and apparently *S. procera*. (*E. T.*).—Cystopteris alpina. (*A Four-years Subscriber*).—Isoplepis gracilis. (*J. P. A., Sirensbury*).—Thunbergia or Hexacentris coccinea. The Fern is Polystichum aculeatum lobatum. (*L. E.*).—1, Adiantum formosum; 2, Cyrtium falcatum; 3, Asplenium Veitchianum; 4, Pteris hastata; 5, Pteris erecta albo-lineata (*Rusticus*).—Your Orchid is one of the Odontoglossums, but we do not recognise which. (*E. Shepton*).—What is called in gardens Pteris crispata, a plant of continental origin. (*W. N.*).—Rudbeckia Neumannii. (*Norfolk*).—Your plant is Euphorbia lathyris. The fruits you want are Late Admirable Peach, Red Roman Nectarine, Coe's Golden Drop or Reine Claude de Bavay Plum, and Florence or Belle Agathe Cherry.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

RELATIVE ENTRIES AT POULTRY SHOWS.

YOUR correspondent from Yorkshire completely bears out my letter to you after the Islington Show, as regards Brahmas in the north. Indeed, there can be no question that many of our "established" breeds do not enter nearly as well as the "cross-bred mongrels," as the Brahmas have been frequently styled. When I entered on my calculations as regards the Islington Show, I did not fancy I could have made out so good a case for them, and I am now going to test the patience, perhaps, of a few of your readers, whilst I analyse the entries of the late Sydenham Show.

At the close of the winter show last year I wrote to the Secretary, urging them, in future, to give greater encouragement to Brahmas, alluding then only to the addition of a third prize. Meantime, the Agricultural Hall Company issue their liberal prize list, in which Brahmas were most liberally treated, and it cannot be denied that they responded well to the invitation. The Sydenham authorities, however, have determined to remain "as they were;" no third prize, no fresh classes. Let me, however, first prove my case by figures, which, in this place, prove only the truth. I alter the order in which the various breeds are arranged in the Crystal Palace Schedule, and place them in the order that they have proved most profitable to the Crystal Palace Company.

Breed in Order of Value.	No. of Entries.	No. of Exhibitors.	Amount offered in Prizes.	Amount realised by Entries.	No. of Classes.
Dorking.....	166	47	£ s. d. 22 10 0	£ s. d. 31 16 0	4
Brahma.....	24	11	8 0 0	7 4 0	2
Bantams.....	65	41	22 0 0	19 10 0	7
Pencilled Hamburgh...	39	26	15 0 0	11 14 0	3
Cochins.....	54	34	21 0 0	16 4 0	4
Spangled Hamburgh...	35	25	15 0 0	10 10 0	3
Game.....	69	36	30 10 0	20 14 0	6
Spanish.....	36	28	17 10 0	10 16 0	3
Malay.....	4	2	3 0 0	1 4 0	1
Polish.....	17	10	15 0 0	5 12 0	4
Other breeds.....	19	12	5 0 0	5 14 0	

Here, the Dorking is undoubtedly much the most profit-

able to the exchequer, and evidently does not get its due allowance of prize money. The Brahmas, the only other breed that nearly approaches a repayment of the prize money, have, however, only £8 offered them in two classes, whilst the former breed has nearly three times the amount, and has four classes.

There are breeds long established, well encouraged, the Polish and Malay for instance, which very miserably repay the exchequer. The latter deserve, and must expect, unless their admirers come forward more thoroughly, to be sent back to the cold shades of the "Any other variety" class, from which limbo the Black Hamburgh ought as certainly to be rescued. At Sydenham five competitors showed five pens, a greater number of entries, than in classes 18, 26, 27, and 30, and equal to Class 32, in all which classes £3 was offered, and in some a larger amount as prizes. Birmingham has this year set aside a class for them, but though apparently alive to the demands of this breed, it offers no greater inducements to Brahma-breeders than heretofore—no fresh class, no third prize, whilst the opening regulation in a spirit of self-laudation, considers "any departure from the extended prize list unnecessary."

It is impossible to say how the entries may tell there, but it is certain that as far as the Sydenham Show is concerned, justice is not meted to the Brahma, and I feel convinced that any impartial observer will bear out my judgment, if he study the catalogue. I have not taken the single cock classes separately, but there Brahmas follow the Dorking, although in the case of Cochins and Game, the prizes offered are larger. In my remarks I do not desire to detract from the merits of other breeds. Indeed, I am very interested, and showed in classes which I have here shown to be weak, numerically, both at Islington and the Palace. To see them docked of some of their offered prizes would be rather a tender spot with me, yet it would be but justice to the breeds that enter numerically stronger.

Our two large metropolitan Shows distinctly prove that the Brahmas are No. 2 as payers, whilst the experience of most who have kept them is, that in utility they are A1, being hardy, easily restrained by fences, rapid-flesh producers, early layers, and, to my eyes, but I may be partial, very handsome.

In conclusion, may I venture to say, that in your hints about selecting birds for show, you have urged points of feather, which I was sorry to see? Making large birds as the Dorking and Cochin, birds of feather, has in past years, done much injury to those breeds, and I would willingly save my pets from such a fate. I consider shape, size, and colour, to be the order of merit.—Y. B. A. Z.

JUDGES SHOULD BE ALONE.

I was given to understand that the public, and particularly exhibitors, are not admitted at poultry shows while the Judges are making their awards. Yet I noticed at the Poultry Show held at Crewe in connection with the Cheshire Agricultural Society on the 30th of September last, that whilst the Judge was making the awards an exhibitor entered the tent with catalogue in hand and went round the different pens with the Judge. When the public were admitted that exhibitor met the owner of a prize pen, and the following conversation took place:—

"Well Mr. — has got the first prize, and we have given you the second, and all the rest have got 'highly commended' or 'commended,' so you must consider it an honour." Now I think if he had omitted the word honour and substituted favour he would be nearer the mark. I do not doubt the Judge, but I do not think that he can perform his duty with satisfaction to all parties during the presence of any exhibitor.—A LOVER OF FAIR PLAY.

MANCHESTER POULTRY SHOW.

"I HAVE received a very good list of prizes to be given at Manchester, but there is one very great drawback, the Show is exactly at Christmas, and the fowls will have to be there during Christmas-day—a very objectionable arrangement, which, I should fancy, would deter many from sending

their poultry. I do not intend to do so unless it is altered, but it struck me when you noticed the prize list, which you generally do in *THE JOURNAL OF HORTICULTURE*, if you concurred with my opinion, you might make some remark upon the unsuitableness of the time. I should have thought the week after would have done as well, as there does not seem to be any great show advertised then. My apology for troubling you must be, that it seems a great pity for such a good Show, that the Committee have chosen such a time for holding it."

[We have not seen the Manchester prize list, but we publish the foregoing extract from a letter written to us by one of the most successful, and most extensive exhibitors, and add our opinion that any arrangement whereby poultry, and, consequently, their attendants are kept away from home at Christmas, is most objectionable. We hope that other exhibitors will coincide with our correspondent.—*Eds. J. of H.*]

CRYSTAL PALACE POULTRY SHOW.

OUR anticipations were fully realised, and amateurs supported this Exhibition in every way. We know not that we ever went to any show where all things were as comfortable as they were here. The two great elements of light and air abound, and with a double row of pens on each side, the whole space of the centre was open to spectators. In our opinion this is preferable wherever possible, to a row in the centre dividing the promenade, as it enables spectators to see the birds without effort or inconvenience, and also allows them the air they need. Experience is not thrown away on so good a general as Mr. Houghton, and accordingly rather than interfere with the *coup d'œil* of the whole, or the comfort of the visitors, he placed the Ducks out of doors, and he did wisely. Ronen Ducks, and still more Buenos Ayrean, require a strong light, and were never shown more favourably than last week at Sydenham. It was a clean and pleasant Show, and as our friend the Bloomer says in "Sponge's" celebrated tour, "May we have to record many such in our imperishable columns." The notice of the classes will, by their length, prevent any further remarks by way of introduction.

We must speak in terms of commendation of the *Spanish*, and here we shall have to notice that which will occur again—the success of a new name. Mr. Parsley was first-prize-taker in every class of Spanish. It need not be inferred from this fact that his victory was an easy one—he was well run up by the second and third prizetakers.

"They conquered all but Parsley;
Parsley, them."

It is unnecessary to say that *Dorkings* were strong. They live on the threshold of the Show. They may be at home at five in the morning, and judged in the Show before nine; add to it that those most acquainted with Dorkings in the Dorking country, have made this their show and tilting ground; yet, on this occasion they were beaten, and a gentleman from Berkshire beat one pen which took first prize. Good names followed. Capt. Hornby was second; Lady Holmesdale third; and Mrs. Fergusson Blair fourth. This says as much as a page of writing. The Rev. Mr. Hodson, Lady Lerge, and Messrs. Priest and Wilcox showed excellent birds. Lady Holmesdale showed some beautiful Buff chickens, which deservedly took first prize. Many most excellent birds were disqualified by bad combs. There are curiosities in these things.

The combs of the White *Cochin* pullets were perfect throughout the class. Those of the Grouse were very good; those of the Buff very faulty. Mr. Stretch was strong in Grouse; and Lady Holmesdale showed beautiful White, beating Mr. Chase. In the *Single Cock* class both prizes were taken by Grouse birds. It is worthy of remark that the Buff was the weakest in point of merit of all the *Cochin* classes.

The *Brahmas* were very beautiful, and formed a strong and attractive class. We had here another new name—Mr. Barclay—who took first prize, but very hard run by Mrs. Fergusson Blair. Mr. Priest's cocks were very good.

We never recollect seeing better *Brahma* classes.

The Black-breasted Reds were the best among the *Game*.

The Piles came next, the Brown Reds were not as good as we have seen them, and Duckwings do not show as well as chickens as they do as adults. The prize birds belonging to Messrs. Stubbs, Rev. G. S. Crawys, and Mr. Matthew were perfect. Messrs. Wood, Pares, and Dawson also deserve especial mention, as do all the prizetakers in these classes. The *Single Cock* class brought the same names to the fore as the others—Messrs. Stubbs, Matthew, and Cock.

It is another of the curiosities of poultry and poultry-showing that the *Hamburghs* are never good alike. Sometimes the Golden, sometimes the Silver are the best. We had on this occasion a show of Silver-pencilled equal to the best days of the class; but the Golden, that have for some time been the perfection of pencilling, were many of them inclined to mossy plumage. Lady Holmesdale took two out of three prizes in Silvers, and is likely, we think, to repeat her victory. Mr. Robinson will also be hard to beat. The Golden-spangled were quite as good as the Silver-pencilled. They formed a truly remarkable class full of good birds, and the competition was a hard one. Messrs. Ellis and Brook may be proud of their birds. In the Silver-spangled, although they were not without merit as a class, yet there were important points that remained desiderata. The hackles of the hens were too light, and some of the cocks were almost white. Even Mr. Collinge's first-prize hen, which had many good points about it, was not free from these defects.

With the exception of the Golden, all the *Polands* are looking up. The Black and the Silver were perfect. In the former well-known names were obliged to be passed over, and in the latter Mr. Adkins showed matchless birds, easily taking both prizes. The *Single Cocks* also called forth the strongest commendations.

The *Melans* were not as numerous as usual. This should not be at the Crystal Palace. These birds are associated for many years with Wapping, Rat-liffe Highway, and the river's side, yet they only sent four pens. Mr. Sykes took both prizes.

We always think the *Various* class a sort of thermometer, giving the height or otherwise of the poultry pursuit. It may safely be said it is at blood heat, if varieties are to tell for anything—Black *Hamburghs*, La Flèche, Houdans, Crève Coeurs, Silkies, Chamois, Foudans, Poule du Mans, Japanese, and many others. It is fair to notice the increase, numerically and in merit, of the *Crève Coeurs* and the Black *Hamburghs*.

The Golden and Silver *Sebright Bantams* were not so good as we have seen. Many of them had the *Cochin* fault of indifferent or faulty combs. The Whites were excellent, the Blacks good, the Game beautiful. Mr. Munn was very deservedly successful, being first and second with excellent birds; Mr. Crawford third. We here venture to repeat that which we wrote so recently: A Game Bantam should not droop its wing like a *Sebright*. There was a time when any Bantam that had the plumage of a Game fowl was a marvel, but that is no longer the case. When twenty good pens compete, Judges look for an approach to perfection. The Duckwings and varieties formed a very interesting class; seven pens figured deservedly in the prize list. Mr. Forrest's Duckwings and most excellent feather-legged White ones called for notice. But the most curious and, we must add, meritorious and attractive pen was one of Buff *Cochin Bantams*—*Cochins* in every respect but size. Mr. Herrick may be proud of his success. The cocks were also very good.

Mr. Fowler was first with *Aylesbury Ducks*, three birds weighing 22½ lbs. The second prize went to a new amateur, Sir St. George Gore, Bart., the weight 20½ lbs. The Rouen class was a perfect one, and here Sir St. G. Gore performed no mean exploit—he beat all competitors, even Mr. Fowler; his birds weighed 18½ lbs., half a pound more than Mr. Fowler's. The highly commended birds weighed nearly 17 lbs. per pen. A beautiful class of Buenos Ayrean brought honours to Mrs. Wolferstan and Mr. Ballance. It is impossible to imagine anything richer than the plumage of these prize birds. They were out of doors, and with the sun shining on them they were the perfection of the breed.

Mr. Fowler took both the prizes for White *Geese*, but they did not weigh so well as they have sometimes done, the heaviest pen 46½ lbs. The same may be said of the Grey, Mr. Dolby's first-prize pen was 54 lbs., Mrs. Seamons' 50 lbs.

Mr. Wright's Turkeys weighed 41½ lbs., Mr. Fellowes 39½ lbs.

The Ornamental Water Fowl all belonged to Mr. Baker—Black Swans, Berwick Geese, and Bahama Teal.

There was the largest show we have yet had of Golden and Silver Pheasants. Mr. Yates and Master Welsh took the prizes. Among the Various Pheasants were Chinese, and some good Kaluges. It would be unfair not to notice, among the Extra Stock, some Jungle Fowls belonging to Mr. Baker, very beautiful and perfect birds.

All went off well, and we congratulate Mr. Houghton on his deserved success. Nothing can exceed his painstaking and his anxiety to do his duty strictly. The number of entries and the quality of the birds shown prove that amateurs appreciate the Exhibition, and have entire confidence in the management.

The following is the list of commendations:—

SPANISH CHICKENS (Cockerel and two Pullets).—Highly Commended, W. R. Hall, Newport Pagnel, Bucks; J. Clews, Walsall, Staffordshire.

SPANISH (Cockerel and one Pullet).—Commended, J. W. Smith, Oundle; J. Barry, Wandsworth Road.

SPANISH COCKS.—Highly Commended, R. Wright, Archway Road, Highgate.

DORKINGS (Coloured, Cockerel and two Pullets).—Highly Commended, C. H. Wakefield, Malvern Wells; J. Smith, Parnham. Commended, A. Stanford, Eatons, Steyning, Sussex; Rev. M. A. Appleby, Church Lench Rectory, near Evesham; R. P. Rivett, Parnham; Mrs. F. Blair, Calbayock, Inchmattine, Inchture, N.B.; J. Ashby, Capel, near Dorking.

DORKING (two Pullets).—Highly Commended, C. H. Wakefield; Right Hon. Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Commended, Right Hon. Viscountess Holmesdale; J. Ashby.

DORKING (White, Cockerel and two Pullets).—Highly Commended, H. Lingwood, Suffolk. Commended, Lady Mary Legge, Holmewood Lodge, Dorking; Mrs. Beardmore, Uplands, near Fareham, Hants.

DORKING COCKS (Coloured and White).—Highly Commended, Rev. J. G. A. Baker, Old Warden, near Biggleswade; Right Hon. Viscountess Holmesdale. Commended, Sir J. Paxton, M.P., Rockhill, Sydenham; C. Smith, Salisbury; Rev. J. G. A. Baker.

COCHIN-CHINA (Cinnamon and Buff, Cockerel and two Pullets).—Highly Commended, Rev. C. Spencer, College House, Attleborough, Norfolk; E. Musgrove, Ormskirk. Commended, J. W. Kelleway, Isle of Wight; S. Statham, Forest Row, Sussex.

COCHIN-CHINA (Brown and Partridge).—Highly Commended, E. Tudman, Whitechurch, Salop. Commended, C. H. Wakefield.

COCHIN-CHINA (White).—Highly Commended, F. W. Zarhorst, Dublin; Mrs. F. St. John, Oakley, Basingstoke. Commended, J. Biggar, Northampton; W. Dawson, Hopton, Miffield, Yorkshire.

BRAMHA FOOTKA (Cockerel and two Pullets).—Highly Commended, J. K. Fowler, Prebendal Farm, Aylesbury; J. Pares, Chertsey; J. Wright, Woodbridge; C. Priest, Muntham Court, Wortham. Cocks.—Commended, Mrs. F. Blair; J. Clark, Chiswick Mall.

GAME (White and Piles).—Highly Commended, Rev. G. S. Cruwys, Tiverton, Devon.

GAME (Black-breasted Reds).—Highly Commended, J. Stubbs, Stafford. Commended, Sir St. G. Gore, Bart., Derbyshire; J. Fletcher, Stoneclough, near Manchester; A. B. Dyas, Madeley, Shropshire.

GAME (Black-breasted and other Reds, except Black-breasted).—Highly Commended, W. Pares, Ockbrook, near Derby; J. Wood, Haigh, near Wigan.

GAME (Duckwings and other Greys and Blues).—Highly Commended.—A. B. Dyas, Madeley, Shropshire.

GAME COCKS.—Commended, G. W. Rawwell, Portsea, Hampshire; J. Fletcher, Stoneclough, near Manchester.

HAMBURGH (Silver-pencilled).—Highly Commended, J. Holland, Chestnut Walk, Worcester; C. Moore, Poulton-le-Fylde.

HAMBURGH (Gold-spangled).—Highly Commended, Sir St. G. Gore, Bart.; H. E. Emberlin, Leicester; H. Carter, Holmfirth. Commended, T. May, Wolverhampton.

HAMBURGH (Silver-spangled).—Highly Commended, Sir St. G. Gore, Bart. Commended, J. Leech, Newcastle, Staffordshire.

HAMBURGH COCK (Gold or Silver-spangled).—Highly Commended, C. Priest, Mearham Court, Worthing.

POLENAS (Black with White Crests).—Commended, T. P. Edwards, Lyndhurst, Hants.

POLENAS (Silver).—Highly Commended, J. Wright, Woodbridge; Countess de Flabault, Tulliball Castle, Kincardine-on-Forth.

POLENAS COCKS.—Highly Commended, G. C. Adkins, Birmingham; H. Carter, Holmfirth.

MALAY.—Highly Commended, Master C. A. Ballance, Taunton.

ANY OTHER DISCREPANT BREDS.—Highly Commended, Mrs. D. Haig, Lichfield (Maggie Partridges); W. Bowly, Cirencester, Gloucestershire (Siskies or Japanese). Commended, C. Coles, Fareham (Andalusian).

BANTAMS (White, Clean Legs).—Commended, Sir St. G. Gore, Bart.; Rev. G. S. Cruwys.

BANTAMS (Black, Clean Legs).—Commended, Mrs. H. Freke, Highworth, Wilts; F. Potts, jun., Newport, Isle of Wight; Rev. G. F. Hodson, North Fetherton, near Bridgwater.

GAME BANTAMS (Black or Brown-breasted Reds).—Highly Commended, Sir St. G. Gore, Bart.; J. K. Fowler, Prebendal Farm, Aylesbury; T. H. D. Bayly, Biggleswade, Beds. Commended, E. Musgrove, West Tower, near Ormskirk.

BANTAMS (Duckwings, or any other variety of Bantams).—Highly Commended, T. Walton, Daventry; W. Lawrenson, Ailceetree, Derby; O. Nicholson; Rev. P. W. Story, Daventry.

BANTAM COCKS (Any variety).—Highly Commended, T. H. D. Bayly, Commended, J. W. Kelleway, Isle of Wight; M. Leno, jun., Dunstable, Beds.

DUCKS (Aylesbury).—Highly Commended, J. K. Fowler.

DUCKS (Rouen).—Highly Commended, W. H. Denison, Woburn, Beds; Mrs. F. Blair. Commended, W. J. Verner, Ryde, Isle of Wight; T. Shaw.

DUCKS (Black).—Highly Commended, Rev. P. W. Story; G. Botham, Slough; Mrs. Beardmore, Uplands, near Fareham, Hants.

DUCKS (Any other variety).—Commended, T. Walton, Daventry (Wild Ducks).

GESE (White).—Commended, A. S. Yates, Bishop's Sutton, Alresford, Hants (Chinese).

GESE (Grey and Mottled).—Commended, Mrs. F. Blair.

TURKEYS.—Highly Commended, Mrs. A. Guy, Grantham (Cambridgeshire); T. Hollis, Reading (Cambridgeshire). Commended, Right Hon. Lady Hawke, Womersley Park, Pontefract.

PHASANTS (Gold and Silver).—Highly Commended, C. Baker, King's Road, Chelsea (Gold).

PHASANTS (Any other variety).—Commended, C. Baker (Chinese Ring-neck).

PIGEONS.

POWTERS OR CROPPERS (Cocks, any colour).—Very Highly Commended, E. L. Curker. Highly Commended, R. Mackley. Commended, E. Body, Portsmouth. Hens.—Very Highly Commended, R. Fulton, Deptford.

Highly Commended, T. H. Evans, Lambeth Walk.

DRAGONS (Blue).—Highly Commended, J. Owens, Walworth Common. Any other colour.—Highly Commended, W. A. Bacchus, Stockwell.

ALMOND TUMBLERS.—Highly Commended, F. E. Elze, Westbourne Grove, Bayswater.

SHORT-FACED BEARDS.—Commended, G. R. Ellenden, Greenwich; J. Owens; W. H. C. Oates, Newark, Notts.

JACOBS.—Commended, M. E. Jobling, Newcastle-on-Tyne; — Esquiant, Oxford Street, London.

OWNS (Blue or Silver).—Highly Commended, Rev. G. F. Hodson; F. G. Stevens, Barnstable, Devon. Commended, C. Eulpin. Yellow or any other colour.—Highly Commended, H. Yardley, Birmingham; H. Morris, Forest Hill.

TURBIS.—Commended, H. Yardley; J. Percival, Rye Lane, Peckham.

FANTAILS (Black).—Highly Commended, F. E. E. Elze; J. Owens. Commended, R. F. Jarvis, Holmesdale, near Dartford, Kent; H. Yardley; H. Morris, jun.

BARBS (Yellow or any other Colour).—Highly Commended, Mrs. Craigie Woodlands, Chigwell, Essex.

TRUMPETERS (Black Mottled).—Highly Commended, F. G. Stevens. White or any other colour.—Highly Commended, W. H. Denison; F. G. Stevens.

HUNTS (Spanish and Leghorn).—Commended, C. Baker, King's Road, Chelsea.

ANY NEW OR DESERVING VARIETY NOT BEFORE MENTIONED.—Commended, C. Baker, (Wonga-wonga, Bronzewing, and Californian Quail).

RABBITS.

BLACK AND WHITE.—Highly Commended, G. Booth, Nottingham (Buck). Commended, Miss Hawksley, Edgware Road, London (Buck); H. Hudes, Norwich (Buck and Doe).

YELLOW AND WHITE.—Highly Commended, H. Handford, Nottingham (Doe); H. A. Silvester, Springhead, Gravesend (Buck); Messrs. Hall and Co., Plumstead, Kent (Buck). Commended, H. A. Silvester (Doe); J. Hinks, jun. (Buck and Doe); G. Jones, Birmingham (Buck); W. C. Boorer, Woolwich, Kent (Doe).

TORTOISESHELL.—Highly Commended, W. C. Boorer (Buck). Commended, G. F. Greensill, Birmingham (Buck); C. Sellen (Doe); H. Hudes, jun. (Buck and Doe).

BLUE AND WHITE.—Highly Commended, J. Morris, jun. (Buck).

GREY AND WHITE.—Highly Commended, J. Harris, Brighton (Buck). Commended, A. Stedman, Oxted, Surrey (Buck).

SELF COLOUR.—Highly Commended, Messrs. Hall & Co. (Buck). Commended, C. F. Pentecost, Kensington, London (Buck); C. Sellen (Doe).

FOR WEIGHT.—Highly Commended, G. Eridon, Chesterfield (Doe). Commended, J. Harris, Brighton (Doe).

FOREIGN.—Highly Commended, Master J. de la S. Simmonds Chilcomb Rectory, Winchester (Buff Silver Grey Doe). Commended, G. Buchanan, Port Vale, Hertford (Angora Buck); Master G. de la Simmonds (Silver Grey or Chinchilla Buck); Master J. Archer, St. Ives, Huntingdonshire (Silver Grey Buck); C. Young, Gipsy Hill; J. Bailly, jun., Mount Street, Grosvenor Square, London (Belgian Doe).

MONMOUTH FARMERS' CLUB POULTRY SHOW.

This was held on the 14th inst. The following is the list of awards:—

GESE.—First, Mrs. A. Jones, Priory Farm. Second, Miss Price, Trewan Goslings.—Prize, Miss Price, Whitfield.

DUCKS.—First, Mrs. Elliott, Tretire. Second, J. Pearce, Wyesham. Ducklings.—Prize, R. H. Nicholas, Malpas.

SPANISH.—Prize, J. Heckley, Wyesham. Chickens.—Prize, J. Pearce, Wyesham.

DORKINGS.—First, Mrs. A. Jones, Priory. Second, R. H. Nicholas, Malpas. Chickens.—Prize, W. Hall, Rockfield.

COCHIN-CHINA.—First and Second, R. H. Nicholas, Malpas. Chickens.—Prize, R. H. Nicholas.

HAMBURGH (Gold or Silver-pencilled).—First, Hon. J. F. C. Butler, Llantilio. Second, R. H. Nicholas, Malpas. Chickens.—Prize, Hon. J. F. C. Butler.

POLENAS (Gold or Silver-pencilled).—First, R. H. Nicholas, Malpas. Second, I. Freyer, Walford Court.

GAME.—Prize, G. Pritchard, Llanvihangel. Chickens.—Prize, J. Jones, Llwynygat.

BANTAMS.—First, G. Aldridge, Monmouth. Second, J. Jones, Redstreak. Chickens.—Prize, W. Hall, Rockfield.

ANY OTHER VARIETY.—First and Second, R. H. Nicholas, Malpas (Silver-spangled Hamburgs, Chinese Silkies).

GUINEA FOWLS.—Prize, Mrs. A. Jones, Priory Farm. Young birds.—Prize, Mrs. A. Jones.

PIGEONS.—Carriers.—Prize, R. H. Nicholas. Tumblers.—Prize, R. H. Nicholas. Fantails.—Prize, R. H. Nicholas.

RABBIT.—Himalayan or Ermine.—Commended, G. E. Bond, St. Leonards.

TWO QUEENS AT LIBERTY IN THE SAME HIVE—LOSS OF THE QUEEN.

MR. WOODBURY has mentioned the death of the young queen which he discovered at liberty in a stock possessing a fertile queen. A few words on the history of the affair may not be unacceptable to apiarians.

Mr. Woodbury having kindly presented this young queen to me, she was added to an artificial swarm on the 20th of August.

September 7th.—A considerable quantity of brood on one comb.

Sept. 16th.—Ditto on three combs. Queen is of a beautiful colour.

Sept. 18th.—Drove the bees of one of my stocks, killed the queen, and united the bees to the artificial stock. With the exception of securing the Ligurian queen, every care was taken. No fighting whatever took place the first day, but on the following one there was considerable, and the queen was destroyed.

Sept. 21st.—Royal cells making. The young Ligurians out in large numbers, proving of first-rate colour.

Sept. 23rd.—Royal cells sealed. Added a common queen, but the bees destroyed her directly.

As it is so late in the season the young Ligurian queen is probably by this time at liberty, but cannot be of any service, and as I do not want to have any except drone-breeding queens, she must be destroyed, and the bees united to an adjoining hive.

This disaster is the more vexing, as I have been in the habit of uniting bees with impunity, having never before experienced such a catastrophe as the loss of the reigning queen, where the precaution was taken of removing the stranger. Probably there is an antipathy between the two varieties, which makes the operation more dangerous. The swarm was populous enough to go through the winter, and I ought to have been satisfied in leaving well alone. It will be a lesson to me never to risk such an operation where a valuable queen's life must be placed in jeopardy.—S. BEVAN FOX, *Esq.*

FOUL BROOD—AN EXPERIMENTAL APIARY.

I REALLY must unite with "B. & W." the Hon. and Rev. W. C. Ellis, and many others who have protested against the tone and style of Mr. Lowe's recent communications.

It may, as he says, amuse old-fashioned as well as modern apiarians to peruse his account of what we may of course imagine to be his own doings, in the character of "the Enigmatical and the Experimentalist," and it may certainly throw some light on the nature of the so-called experiments—save the mark!—which have misled him in the matter of foul brood.

Although I have never done so, I will not deny that it may be possible by means of mismanagement, so to paralyse a colony of bees by an overwhelming quantity of chilled brood, as to simulate some of the evils and not a little of the appearance of actual foul brood. And this is what Mr. Lowe has evidently done. He first crushes the energies of his unfortunate bees by an overpowering mass of chilled brood, and when they sink desparingly under the incubus, he declares authoritatively that "decayed and abortive brood in all stages are not removed by the bees, and consequently must remain a permanent evil in whichever hive they are unfortunately found." Having arrived at this satisfactory conclusion, our experimentalist proceeds to relieve his miserable bees from the intolerable evil he has himself inflicted on them; and when with the indomitable spirit of their race they set to work to repair the ravages he has made, and possibly even ultimately prosper in spite of his ill-treatment, he triumphantly announces that foul brood "is an evil with which I have long been familiar," and "I have found that excision of the affected parts is sufficient." That he is mistaken with regard to the general indisposition of bees to remove chilled and therefore abortive brood I shall presently show; that he is equally in error with regard to foul brood being amenable to any such half-measures as he describes has already been abundantly proved; he will also

in due time find this out for himself, whenever it may be his misfortune to meet with the true disease in his apiary.

On the 19th of August, I perused Mr. Lowe's reprobation of my proceedings in allowing brood to remain a dozen hours in a warm kitchen, coupled with the assertion that under such circumstances foul and abortive brood would follow as a necessary consequence. There is something almost provokingly absurd in gravely experimenting for the purpose of establishing a fact already so well known, and one which in a few months' time the merest tyro in apiarian matters may verify for himself by a cursory examination of the ground in front of a good stock after a sharp spring frost; but it so happened that I had by me a large piece of comb crammed with brood in all stages (principally sealed), which I had cut out of a hive in the North of Devon, four days previously, and which I had brought home and left uncaressed for in a fireless apartment. Here, then, was an opportunity for an experiment—not certainly in Mr. Lowe's slashing style, but quite sufficient for the purpose—and I accordingly placed this comb—this mass of chilled and abortive brood in all stages—in one of my colonies which had only recently been cured of foul brood by the means described by me in pages 97 and 98, and sneered at accordingly by Mr. Lowe. What was the consequence? The re-appearance of foul brood? No. Was the comb suffered to hang a putrefying and corrupt body in the midst of an inert and despairing population? Not a bit of it. The bees at once set to work and dragged out every defunct embryo; a few of the younger ones were, I believe, even hatched after all this neglect. The queen deposited an egg in every cell as soon as it was emptied, and all hatched out in due course; and the comb now worthily maintains its place as part and parcel of the furniture of a thoroughly healthy stock. So much for Mr. Lowe's dictum so authoritatively laid down.

Having, therefore, refuted Mr. Lowe's singularly erroneous assertions, the question of *cui bono?* must necessarily arise; and I would ask him in all seriousness, whether he believes such proceedings as he has portrayed are likely to advance the cause of apiarian science? I care not whether it be, as I have shown good reason for believing, a more or less accurate description of his own manoeuvres, or whether he intended it as a caricature of what he imagines to be the proceedings of others; but I would ask if such an epistle as his last is at all likely to aid in developing the true principles of apiculture?

It is also to be regretted that Mr. Lowe has not responded to his own appeal and been "candid for once." In page 304, I took leave to correct one of his misstatements of my words and meaning. These are again so numerous in his last article, that it would be tedious to particularise them. I will, therefore, merely notice a couple of specimens. First, then, I stated in page 97, that "Dzierzon declares that every hive that has contained a foul-breeding colony should be exposed to the sun and air for two years before being restocked." This period Mr. Lowe has enlarged to "four years," apparently for no other purpose than that of enabling him to ask ironically "Would not three years and a half do?" A few lines further on, he quotes, or rather misquotes a sentence in inverted commas. Need I say that a great part of that sentence was never written by me, and, that as misquoted, it distorts and exaggerates my meaning?

I have, I believe, conducted my share in this discussion with fairness and moderation, and if Mr. Lowe will follow my example, I shall be at all times ready and willing to exchange with him, in the pages of THE JOURNAL OF HORTICULTURE, the results of our mutual observations and experience. If on the other hand he prefers endeavouring either to snatch a questionable advantage, or to conceal a defeat by resorting to misrepresentation and sarcasm, he will neither be imitated nor again replied to by—A DEVONSHIRE BEE-KEEPER.

ACCLIMATISATION OF HONEY BEES.—Dr. A. Gertsäcker, in concluding a very extensive memoir on the distribution of the honey bee, observes that the most valuable form for Europe would be the Egyptian, partly on account of their beauty and partly because of their unwillingness to use their stings, which appears to be common to all African bees,

and is also one of the recommendations of the Italian bee. The Syrian bee agrees so closely with the Egyptian that it may prove equally valuable; and next to these in value are the bees of the coasts of Asia Minor.—(*Annals of Natural History*.)

LIGHT-COLOURED POLLEN.

My bees, like Mr. E. Fairbrother's, are busy collecting large quantities of light-coloured pollen, no part of which can possibly be drawn from fuchsias, as these are now totally bereft of leaves as well as flowers, having, along with the dahlias, been cut down by the sharp frost of the 5th inst.

Being curious to ascertain from whence the bees obtained the supply, I traced them to the yellow weeds called "Skillochs" (specimen herewith), by the country people in this quarter, and blooming abundantly at this season on some soils, and very possibly the yellow flowers to which your correspondent refers.—A RENFREWSHIRE BEE-KEEPER.

[The "Skillochs" sent by our correspondent is the charlock, *Sinapis arvensis*.—EDS. J. OF H.]

BEEES IN FRAME-HIVES.

We are obliged to the writer of "Apiarian Notes." Will he kindly say if his bees attach his frames to the sides of the boxes, and what he considers the best distance between a frame and the box—top, bottom, and sides, so that they may not be joined together by the bees? Mine have done better this summer, I only lost my stock in the way referred to in my former communication. I do not think this was from foul brood; nevertheless, I have always found some few decayed and stinking larvæ, but I can hardly yet believe this was the cause of their leaving their hive. I have always been of opinion that the bees leaving was the cause of the foul brood. The subject deserves very close attention, and I for one am deeply interested in the lively manner in which it has been discussed, and the gentlemen engaged in it deserve our best thanks.

I have taken great pains this summer to weigh one stock and its swarms day after day when practicable, but I fear it would not be found of sufficient interest to your readers.—EDWARD FAIRBROTHER.

[1st. I have never found my bees attach their combs to the back and front of the boxes in a line with the frames, and in only a very few instances have they united the outer combs to the sides of the boxes. Where this has been done it has almost invariably occurred to frames of comb too wide for the space in which I have inserted them. In shifting frames from one hive to another, the combs will often come in contact with each other and the sides of the box. All that is requisite is, within a day or two to remove each frame and pare away the parts of the combs which have been united by the bees. This plan is constantly followed by those apiarians who desire, for scientific and practical purposes, to have complete control over the frames throughout their apiaries. Without this facility frame-hives possess little if any advantages over ordinary boxes; but with it the pleasure and interest in the observation and management of bees are incalculably increased. It may appear strange that the bees do not bring the combs outside the ends of the frames so as to attach them to the box, and at first I supposed that they would frequently do so, but the bee-master prescribes the form and shape of the comb he wishes them to construct; and I have found that, like some human individuals, they are content, to use a well-known phrase, "to accept the situation."

2nd. The distance I allow between the frames and the box in every part, top, bottom, and sides, is exactly three-eighths of an inch. This will be found near enough to prevent elongation of the ends of the combs, and distant enough to allow of easy removal of the frames without crushing bees between them and the box. The only place where bees will construct their combs outside the frames is on the top, and here they are rather fond, in a good honey season, of filling up the space between the cover, or adapter, and the tops of the frames. When the cover, or adapter, is thus fastened down, a little force in a twisting direction is necessary. The

broken comb attached to the cover must be always scraped away. My first frames were not sunk in separate notches, but rested on a rabbet three-quarters of an inch in depth, which extended the whole length of the back and front. Although this plan possesses some advantages in the removal of full frames, yet I found the force occasionally necessary to remove the top would shift the frames from their places, and have, therefore, latterly adopted the plan of sunk notches below a three-eighth-inch rabbet. The dimensions I have adopted for my boxes are larger than those recommended by my friend Mr. Woodbury, but I consider his hive to be of the size likely to be most generally useful. The Woodbury-hive, as sold by Messrs. Neighbour, of 149, Regent Street, is a first-rate article, and is made either of straw or wood. The excellence of the work in the square straw hives must be seen to be appreciated.

3rd. I will not now enlarge upon the subject of "foul brood," as I hope before long to fulfil my intention of making this the theme of a separate paper.

4th. I should be very glad if Mr. Fairbrother would favour us with the table of the daily weights registered by his hive and its swarms, giving the hours of the day or night when the observations were taken. Having had a suspended hive in operation during several months of this summer, I should like to compare the results in the two localities.—S. BEVAN FOX.]

FERTILE WORKERS.

HAVING brought our bees home from the heather on the 26th of September, I looked at the hive whose bees were laying drone eggs, which I noticed in a communication appearing in your Number of Oct. 6, and found eggs just laid, and certainly no queen. There were only 220 bees altogether, as we counted them; so that there is not the least doubt whatever that bees with no apparent difference to the eye are still capable of laying drone eggs. I introduced a queen to the bees, thinking they might fight when the rival egg-layer came in; but instead of this they would have taken the queen to reign over them. If it would be of any use I would very gladly send the bees to Mr. Woodbury that he might make a microscopic investigation of them, and find out the bee or bees which were laying.—ALEX. SHEARER.

[I am much obliged by Mr. Shearer's kind offer, but the detection of the actual egg-layers is far beyond my skill as a microscopist. Although I have had several such cases (two during the present year), I never could succeed in distinguishing fertile from ordinary workers. In reply to a private inquiry I may add that I esteem breeding an advantage at any season whether late or early.—A DEVONSHIRE BEE-KEEPER.]

FOUL BROOD.

In answer to Mr. Woodbury's remarks in No. 133, Oct. 13, I have to state that the isolated sentence he quotes should have been given *in extenso*, in its entirety, and considered in connection with the context. The language I did use was this:—"If it is to be termed a disease at all, let it be described, as Mr. Taylor described it in last Number, an entirely 'artificial one.'" The words, "an entirely artificial one," are Mr. Taylor's, and all those in italics Mr. Woodbury has thought proper to leave out. The sentence is put hypothetically, "if it is to be termed a disease," if writers persist in calling it so, if they will have it so, if, because the evil is produced frequently, and principally, by ill-timed and wrong-directed artificial processes, then "let it be described as Mr. Taylor described it, &c." But to show what my own views really were, and that I did not choose so to designate it, I immediately added "abortive brood, however, can never be classed under the category of bee maladies." I illustrated my views. The embryo chick in the chilled egg dies, but in common parlance we do not say of disease; and so of a great number of accidental and other kindred deaths among the old and young of all creatures, we do not designate these as produced by disease, properly so called, and so, also, of foul or abortive brood.

In other parts of the same article I say, "If foul brood be a disease, I should like to know by what it is caused?"

Again, "I know of no writer who has, in my estimation, satisfactorily accounted for the presence of foul brood in a hive on the supposition of its being a disease." And, again, "I am not disposed, therefore, to view the presence of foul brood in a hive as a disease, properly so called, at all." And, lastly, to prevent any misconception of my views, I said, "Let me here anticipate any objections which may be urged to the evils in question being produced only artificially," and went on to show that foul brood may be frequently produced "from purely natural causes," and without any interference or meddling whatever.

These quotations will show that I repudiated the doctrine of foul brood being considered as a disease at all. Indeed, I was scrupulously careful not to designate it as such in any of my papers, and, consequently, I must repeat that I did not treat the subject on those principles.

I can assure Mr. Woodbury that I have no intention of "withdrawing from the discussion."—J. LOWE.

BEE-KEEPING IN STAFFORDSHIRE.

I RECEIVED the following letter some time ago from a gentleman in Staffordshire, to whom I am personally an entire stranger, and upon my acceptance of his extremely liberal offer, it was followed by a truly magnificent stock of bees. I, of course, lost no time in returning my warmest thanks; and as my esteemed correspondent is pleased to express himself indebted to me for information on bee management, I solicited and obtained permission to publish his letter, which shows that although he has adopted my hives and experimental system, he has entirely escaped the evils which have been so erroneously described as the natural consequence of the experiments of—A DEVONSHIRE BEE-KEEPER.

"DEAR SIR,—If a stock from a prosperous apiary is likely to assist in stemming the downward torrent, I shall have great pleasure in presenting you with one of my swarms containing a young queen which has proved herself very prolific.

"My own bees have done wonders, as the following statement will show:—

"May 9.—I made my first swarm. In ten-frame hive nadired and bell-glass.

"May 20.—Ditto second. In nadired ten-frame straw Woodbury-hive.

"May 23.—Third swarm came off naturally. (This I will send you.) Is nadired in thirteen-inch bar-hive.

"May 26.—Fourth swarm came off naturally (my best queen). Nadired and bell-glass in Bevan-box, eight bars.

"These are all from one hive, but the first swarm was peopled by placing it on the stand of another hive.

"June 24.—Swarm of May 9th, sent out a strong swarm, although it had been transposed on the 16th with swarm No. 2, in large straw hive.

"July 3.—No. 1, of May 9th, sent out a large second swarm. This I returned but had to nadir their hive to prevent clustering, although they were in a ten-frame hive and surmounted with a large bell-glass.

"July 10.—Maiden swarm of June 24th, sent off a good swarm which was unfortunately lost, having taken refuge in a church roof three-quarters of a mile off. I had transposed on or about the 7th this swarm with one from a storified-hive of June 23rd, which began to cluster outside, and this made them swarm. By this transposal the two swarms changed their working population almost entirely, as they were hived within a day of each other, and brood had matured in both hives. Notwithstanding this misfortune both these hives are very populous, and I have had to nadir the swarm of June 23rd containing the population of the maiden swarm to prevent hanging-out. The other hive, the maiden swarm, is well filled with bees, and if we have a few more honey days will stand the winter without feeding.

"I have thus unfortunately lost my two best queens from last year. The one was cast out of her hive dead, and the other, the mother of these numerous colonies, went off with the maiden-maiden swarm.

"I made a hole in the roof of the church and arrived close to the cluster of bees, and having cut down the combs

which they had constructed after an occupancy of only three days, so as to fall on a shallow paper tray, drew them forth in hopes of obtaining the queen, but she and the bulk of the bees crawled higher up under the roof and baffled my attempts. I have made several unions this year in the method recommended in THE JOURNAL OF HORTICULTURE with the most perfect success and without the least fighting. The smell of the peppermint effectually prevents the bees from recognising each other, or discriminating between friend and foe.—J. E. B."

AGE OF QUEENS.

I AM afraid that "A DEVONSHIRE BEE-KEEPER" has been rather too precipitate when he says that the one case decides the question as to the age of queens.

For example, a number of years ago, while examining my hives in autumn to ascertain their state for stocks, my attention was particularly drawn to two of them from the immense quantity of brood they possessed, and which was apparently in good condition and promising well for a future year, and, as a matter of course, carefully covered up for the winter. Having passed inspection I looked no more after them till spring, when I noticed a dwindling-away. My suspicion was at once aroused that there was something wrong. An examination of No. 1 took place, and thinking there was no queen from the fact of there being no brood in the hive, I turned out the bees to satisfy myself; and to my astonishment I found the very same queen that had already proved herself so prolific the autumn before, actually producing no eggs whatever though scarcely two years old, and the worker bees paid no attention to her any more than if she were an ordinary worker bee. No. 2 had also ceased to produce bees. The only things in the shape of brood or young in this hive were one drone and one working bee, and thinking there was some chance of their doing well, I allowed them to remain; but ere many days they left the hive, leaving nothing but the queen bee and drone in the hive. This queen was three years old. Although this appears to corroborate "A HANTS-IRE BEE-KEEPER'S" opinion, I am sure it is only an exception.—A LANARKSHIRE BEE-KEEPER.

[This is almost the only case in which I cannot support my opinions by my own experience. It does appear to me, however, that Mr. Lowe's evidence, as well as that of "A LANARKSHIRE BEE-KEEPER" himself to say nothing of all other authorities on the subject, prove most conclusively that seven years is a very exceptional age for a queen bee to attain—so exceptional indeed, that I am still inclined to fancy it, in the language of our police courts, "a remarkable case of mistaken identity."—A DEVONSHIRE BEE-KEEPER.]

OUR LETTER BOX.

SPANISH COCKERIL MOULTING (*Subscriber*).—The cause of the appearance you name is a little weakness at the time of moulting. The cure is patience. If you remove the false quill, or case, that covers any of the feathers, you will find it perfectly formed within.

ACCELERATING MOULTING (*Vesicarius*).—Let the bird roost and be housed as usual. Feed him well, but not on stimulating food. Let him have ground oats mixed with milk. If he has no grass run give him lettuce. Avoid meat and tomatoes.

DORKINGS FOR BIRMINGHAM SHOW (*G. P.*).—Let your Dorkings run about. Feed them well on soft food, bread soaked in milk, oatmeal, or, failing that, barley-corn mixed with milk. Be sure they are fed at day-break. If they have far to travel give them some bread and ale before they go. Wash their legs and feet before they go, and let them have some clean straw at the bottom of their basket.

ROUPEY TURKEYS (*M. R. D.*).—The disease your Turkeys are suffering from is roup, and the remedy you have adopted is for gapes. Give the patients bread and a freely. Let their faces be washed with vinegar and cold water, and let them be kept in a dry place. Change their ground if you can, and separate the unsound from the sound. Use Bailey's pills.

SPANISH COCK'S COMB PROOFING (*R. A. G.*).—If the cock's comb was quite erect before moulting, you may fairly hope it will be so again. We cannot say as much for the chickens. It is useless ever to keep a Spanish cockerel with a falling comb. He is useless for exhibition, and worthless for sale. Falling combs have been remedied by being tied in an erect position with silver wire, but few birds are worth the trouble and expense, as no one would be bred from such.

SILK-WORM'S EGGS (*S. L. L.*).—You can purchase them in Covent Garden Market. They only require to be put into a box strong enough to avoid being crushed during the voyage.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 52.1°, and its night temperature 36.7°. The greatest heat was 63°, on the 5th and 6th, 1834; and the lowest cold, 18°, on the 9th, 1843. The greatest fall of rain was 1.02 inch.

GARDENERS' BENEFIT SOCIETY.

ALLOW me to thank the Editors for the interest taken, and the labour bestowed, in perfecting some part of the scheme which I so sanguinely propounded in the spring of the year. Permit me also to congratulate my brother gardeners on the fact, that the Editors were placed in a position to announce "that steps were taken to form the Society." I

would also thank those that have already given their support to the measure, more especially Mr. F. Clitty, for it was he only that had any critical remarks to

offer upon it. Whilst doing so I cannot forbear noticing the reserve with which the members of the profession have treated the question, nor can I help expressing my astonishment at the little interest we gardeners take in all measures proposed or established to further our advancement. We seem as if we had no Saxon blood within us, nor any of that brotherly sentiment which strives to mitigate those infirmities and calamities that befall humanity in one shape or other. Other members of special occupations have had their unions, and other working men (I would like gardeners to feel that they are dependant on their own endeavours), have been banded together as one man to mitigate and relieve each other's infirmities, and to bear each other's burdens. This is, indeed, charity, a brotherly feeling, and something more. They have periodical meetings, when all meet together, congratulating each other on their general well-being, or sympathising with their sick brethren, to whom they administer relief according to their regulations. What a gap is there between us and them! We have long had a society for our disabled men and disconsolate widows, but what support have we given it? Some have given a mite; others, and by far the greater number, could not spare a yearly contribution of £1 to provide against those infirmities that disable them or their brethren. They would do nothing to benefit others, nor have anything in store for themselves against the day when it is needed, nor feel the pleasure of giving others what they are blessed in not needing.

The greatest drawback, however, to gardeners subscribing to the Gardeners' Benevolent Society, is the circumstance of non-subscribers being placed on the pension list in preference to the subscribers to its funds. That this admirable institution has done much good must be patent to all, and that it is worthy of every gardener's support few will deny; but that it contains anything in the way of gardeners supporting their own sick, or even the majority of the "worn-out," is not presumed: therefore, the Society newly proposed is not framed out of antagonism to it, but to supply a want it does not deal with. I think it prudent to state this, for after the new Society was proposed, it was said in my hearing, that the

new one was got up in opposition to the "Gardeners' Royal Benevolent Society." Since that the scheme I proposed has been framed on what I may term, an amended and more popular basis. Instead of being an improvement, annuity, and benefit society, it is to be a benefit or friendly society only; and as in matters of this kind when a bill is brought in by a private member, and the government offer a counter proposition, or take the question into their hands, the member gives up all care of it. So with the question now before us. When the Editors took the matter in hand, I fell into my private position. I was glad to do this, for it must be evident to all that the matter could not have fallen into better hands.

Although thankful for the small slice of the reform, they (the Editors) think we are at present entitled to. I am not the less convinced that the whole scheme as propounded by me will ultimately be carried out, nor the less certain that what I then said will hereafter be said with the unanimous voice of the gardening community. Men have been more sanguine than I am over many greater things, and I could name in proof at least a thousand.

It would appear pretty certain, from what I learn, that we are to have a Friendly Society: therefore, the following information relating to such societies may not be uninteresting to the general reader, whilst acting as a sort of preliminary to the discussion of the proposed Society.

Daniel Defoe, author of "Robinson Crusoe," in his "Book of Projects," published in 1696, was the first to propound the scheme which has resulted in the formation of friendly societies. Some writers, however, were of the opinion that the ancient guilds of our Saxon and Norman ancestors were identical with our friendly societies. This, nevertheless, could not be the case, for it was only after the extinction of serfdom that workingmen became dependant upon their own efforts. There certainly was no such society in Defoe's time, for in his "Book of Projects; or things desirable to be done," was a scheme for the formation of societies, the contributions from the members of which would provide for relief in sickness and old age, and not only for the members but their widows and orphans. He stated that "if such societies were formed, it would do away with pauperism, shut up poor-houses, and close the jails."

Nine years after, or in 1705, the first society was formed. Two years prior to this, or in 1703, the first bill was introduced into the House of Commons. It passed the Commons, but was thrown out in the House of Lords. Another bill was introduced afterwards; and the renowned Mr. Pitt, with his customary forethought, could so far see the benefits likely to accrue to the country by the formation of friendly societies, that he gave his support to a bill brought in by Mr. George Rose. The bill passed both Houses of Parliament, and became law in 1793.

After the passing of the bill, friendly societies became general; but owing to the careless manner in which the early societies were conducted, and there being no sound data to found them upon, some of them collapsed at the

very time when the benefits promised were required. Declamation upon declamation has been poured forth against working men on the score of ignorance and imprudence in this respect. Their failures were more due to the want of sufficient experience on which to found such societies. Most of the greatest blunders were made by the actuaries, who were really incapable of framing tables for the safe guidance of these societies; but after long experience sufficient data have now been obtained, showing the exact basis on which such Societies should be founded. The data furnished by long experience seem to point to four laws, which it would appear ought to be borne in mind and acted upon, if the Society formed be expected to meet all demands upon it, and remain prosperous:—

1st. The rate of contribution should be graduated according to age. The young, because less liable to sickness and death, should pay smaller contributions, as they are likely to contribute much longer than the old. Others, because more liable to sickness and death, therefore not likely to contribute so long, must pay larger contributions.

2nd. The contributions should be such as to leave an annual surplus, which, being invested on good security, would act as a guarantee fund in times when disease and death are unusually prevalent.

3rd. Such societies ought not to consist of few members in a lodge, for the expense connected with a small lodge would be equal to that where the lodge was four times its numbers. The strictest economy ought to be rigidly enforced in regard to the management of these societies.

4th. The invested capital should be laid out at a reasonable rate of interest, for when the rate of interest is high we may be sure the security is bad. High rates of interest on questionable security (of which they are indicative), are to be avoided.

When societies are framed on the conditions named, with an efficient staff of members as officers, wholly or mostly unpaid, a suitable meeting place, and the whole governed by rules made or confirmed by the whole of the members at a general meeting, there is no fear of the society not working satisfactorily.

Friendly societies, to take a retrospective view, have greatly assisted in raising the social and moral condition of working men. Since their formation the working classes have made great progress in the arts and sciences. They have also promoted habits of sobriety and industry, and better than all, frugality, and been a direct means of diminishing the poor rates. Mr. Tidd Pratt, I think, calculated that no less a sum than £2,000,000 sterling is annually saved to ratepayers by the formation of friendly societies. This sum is, no doubt, somewhat in excess of the real amount saved; but when we consider that three millions of working men belong to these societies, that their contributions amount to £5,000,000 sterling annually, and that they have invested capital to the extent of £11,000,000, we cannot but be pretty well sure that a very large sum is annually saved to ratepayers, for many families that are now relieved by friendly societies would otherwise be obliged to claim parish relief when the head of the family was prostrated by sickness.

Lord Bringham has calculated that working men have in these societies a reserved capital of not far from £20,000,000 sterling, and in the saving's-bank £40,000,000, or between £50,000,000 and £60,000,000 in all, which is demonstrative of the saving habits and self-reliance of British workmen. The men who contribute to these societies are just the men that seek to render poor rates unnecessary. They strive to keep away from the last refuge of the prodigal and unproviding. But all these benefits are nothing when compared with the moral influence exerted on society by these saving habits, which not only benefit the members individually, but the community generally, by teaching the young self-reliance or dependance upon their own endeavours, all being taught the value of law and order. They also fit men for more important positions in society, and further man's moral and intellectual advancement.

Thus much good they do, but they might do much more. They might make a special provision for the widow and the fatherless children of a deceased member, not so much to render permanent assistance, but temporary relief in special cases. I allude to those members cut off in early manhood, leaving, perhaps, half a dozen children totally unprovided

for. It is very productive of misery when it occurs, and the removal of a widow with half a dozen helpless children to the workhouse is a sight that has few equals in amount of sorrow.

Now, supposing a fund raised by entrance fees and private donations were specially set apart for this purpose, would not the interest resulting therefrom afford relief to these especial cases, and the capital itself form a guarantee fund in addition? I think it would, and I should like to see a fund, in connection with the Gardeners' Benefit Society, specially set apart for the relief, temporary or otherwise, of fatherless children and distressed widows of deceased members. If members under twenty gave 10s., above that but under thirty years of age £1, and so on, with the donations likely to flow into the exchequer from the many amateur lovers of gardening, I am persuaded that we could raise a fund that would do even more towards the object in view than the most sanguine amongst us could credit. I do not see the propriety of adding invested capital to invested. I had rather see the interest devoted to a good purpose, than derive any pleasure from the thought "we are becoming rich." What is the use of money hoarded up to meet the wants of the next generation? Secure your solvency by a guarantee fund at the commencement, and nothing short of the grossest and most wanton negligence in the administration of affairs can affect your solvency thereafter.

Allow me now to go into committee on the Gardeners' Benefit Society, it being my object to sift it, and to debate the whole question as if I were able to attend the preliminary meetings of the Society.

I think the rate of contribution is too high for the benefits promised. The Foresters, Odd Fellows, &c., give the same pay in times of sickness as the Society proposed for the same contribution; and also £10 at the death of a member, and £5 at the death of a member's wife, and yet these Societies have an invested capital to the extent of several thousands sterling each; the Foresters being the richest, and the Odd Fellows the strongest numerically of all societies of the kind in this country.

The examination-board, I think, is objectionable. Being connected with gardening gives men no claim to act as examiners unless otherwise fitted for the office; and if they are to be gardeners, I would just as soon stand before a Chinese interpreter and be examined in that peculiar language. Examiners should have certificates of a high order themselves, or I certainly could not expect anything like justice to be done.

On Rule 3 I beg to propose that "Benefit members shall be those who contribute for themselves," omitting the words, "or others." Sir John —, or her Ladyship, might contribute for her gardener; he might leave, another come, and they both be ill during the time they lived under Sir John, and derive in that way more benefit from the Society than those members who were not so niggardly as to let their masters do what they ought to do with pride themselves. Employers' contributions ought to be given for the general benefit of the Society.

On Rule 18 I move to insert after the words, "Any person wishing to become a benefit member of the Society, shall satisfy the Directors as to his character," these words, "Give proof of his having been a gardener for the last seven years, if above twenty-five years of age, &c."

A conservative or protective scheme this! Decidedly. We want something to distinguish who are and who are not gardeners. We must draw a line somewhere. If all men that work in gardens are gardeners, we must be strong numerically, and ought to have had at least 10,000 names by this time.

On Rule 19, I should like to see a clause inserted for gardeners when out of employment, relieving them from contributing at such times, providing always that their non-employment is not caused by carelessness, idleness, or culpable negligence. I have known many gardeners out of employment for two years, twelve months, and between that and six months very commonly, through no fault of their own—I have myself been unemployed for nearly six months. This, when a man has a family, and the low wages we receive when in employment, prevent our laying by much against rainy days; and such small savings will hardly enable a man to keep his family from starving, much less to contri-

bute to a benefit society, when out of employment. A member thus exempted from payment when unemployed would have his contribution carried to his account, which he would be required to pay—i.e., the arrears as well as his regular contribution—on his obtaining full employment. It would be highly mortifying to members to be discarded the Society because misfortune hindered their being able to meet the contribution required by the Society. The Odd Fellows are acting upon this principle during the prevalence of the cotton famine, and are now relying on the accumulated funds of the Society.

I have only to add that I am one of those most likely to derive great benefit from the establishment of such a Society. There are some that have no apparent necessity to join societies of this kind; but I would ask such, Are you prepared to avow that you are not inclined to strive to alleviate the suffering of your fellow men? We rely on your aid, your counsel, and good wishes for the furtherance of the general well-being of the infant Society, not only on account of the great benefits to be derived from it by our unfortunate and afflicted brethren, but to uphold the character of the craft, and to bring out the philanthropic qualities which other men abound in, and for which we have been too long undistinguished. Also, remember, we want those most unlikely to need relief to become benefit members; but at the same time honorary members will give such donations and subscriptions as will place us on a sure foundation, and be the means of our occupying the position we ought long ago to have held. It cannot be expected that the Society to be established will suit all; but whatever it be, so long as it is the decision of the majority, I pledge myself to act and abide by that decision.—G. ABBEY.

WINTERING GERANIUMS IN A SPARE ROOM.

The successful wintering of Geraniums in a sitting-room depends so much on the previous treatment to which they have been subjected in propagating and managing them up to the time that inclement weather renders it necessary to house them, that we think it necessary, in answer to "AN OLD SUBSCRIBER," to enter somewhat into details on these points, as well as on the treatment most likely to insure success after they are placed in the room for the winter.

It is taken for granted that the "Pelargoniums," from the number of young plants which "AN OLD SUBSCRIBER" is anxious to preserve, are not what are commonly called Pelargoniums, but the varieties of Geraniums now so much used for planting-out in summer; but should we be mistaken in this matter, the treatment that is best for the one section is very applicable to the other, as far as their successful preservation in winter is concerned.

Keeping in view the object in which our correspondent is more immediately interested—namely, success in keeping her plants robust and healthy through the winter, we will first speak of the propagation of the plants, and in doing so we would point out several errors into which amateurs of limited experience very generally fall. In the first place, the operation of propagating is delayed till much too late in the season, and then the cuttings selected are far too small; the tips of the shoots, about 3 or 4 inches long, being chosen. Now the successful wintering depends to a very great extent both on the size of the cuttings and on the time they are put in. Under all circumstances, and more particularly when they have to be wintered in spare rooms or any similar place, the cuttings should be put in before the middle of August; and instead of taking the mere soft sappy points of the shoots for cuttings, these should be taken sufficiently large from the plants to have that portion of them, at least, which is to be inserted in the soil of well-consolidated wood, and altogether they should be from 6 to 9 inches in length, according to the size of the respective sorts, instead of three and four-inch cuttings, as commonly used. These strong well-organised cuttings root more speedily and with scarcely any failures, they give far less trouble in winter, and in spring make finer plants. So much for the nature of the cuttings and the time of putting them in.

To preserve them, after they are struck, with the greatest possible success we recommend pots instead of wooden boxes. Although we have wintered hundreds of thousands of cut-

tings in boxes with great success, yet it has always been most evident that those in pots were always in the best condition in spring; and for convenience in wintering them in sitting-rooms pots are most desirable, and those known as 24's or eight-inch pots are the most serviceable. But in whatever vessels they are propagated these should be well drained to begin with, and then filled up with a compost consisting of equal proportions of loam, leaf mould, and sand, and when these three constituents cannot be conveniently had, as not unfrequently happens, the next best to use are equal proportions of common light garden soil and road drift, two elements which are easily obtained by most people who attempt gardening. The cuttings should not be inserted thicker together than at the rate of twenty to the square foot, and strong-growing sorts not so thickly. There is nothing gained by the crowding system, especially in the case of such as our correspondent, who wishes to winter her plants successfully in a spare room, and who has no glass house in which to push on in spring plants that have been injured by being crowded in winter. After the cuttings are all in, the best place to set them to root in is the hottest possible spot out-doors—that is, where they can get most sunshine, and be freely exposed to air. We never find Geraniums struck under glass or anywhere else thrive so well as those rooted out of doors—they are so hardy and stubby when housed as compared to those struck under glass or in room-windows. When the cuttings are made, all the big leaves should be removed except a few at the top of the cutting, and ever afterwards they should not be allowed to become crowded with superabundant foliage. The air should play freely through them, so that the young plants may become solidified and hardy. They should be left out-doors till danger from frost or the heavy rains of autumn render it necessary to protect them: and if this can be done in some temporary way, so as to shield them from both rain and frost, and at the same time expose them freely to all sunshine and dry weather till near the end of October, it will be preferable to putting them into a sitting-room, unless the trouble be taken to put them out-doors every fine day, which is better still if the labour would not be too much.

By carrying out the treatment indicated by the foregoing directions the plants will be stiff rustling "stuff" that will be much more proof against damping and mildew, the great enemies of soft, flabby, coddled cuttings that are put in late, and struck in some confined shaded position. After housing them for the winter, no more water should be given than is necessary to keep them from flagging, and that will be very little indeed. We often look with something akin to pity on Geraniums which are struck late, and placed in sitting-room windows with barely a root to them, to be gorged with too much water—treatment which ends in a large per-centage of death and a miserable remnant of wretched-looking plants. On the shelves of our vineries we winter thousands of Geraniums, and from the beginning of November till February we seldom give them a single drop of water, and if this is considered good treatment on the shelf of a dry vinery fully exposed to all the sun and light that such a position can afford, it will readily be inferred that we recommend them to be kept very dry at the root, more particularly when they are to be wintered in a sitting-room, always a dark place as compared with the shelf of a vinery. It is much preferable to allow them to flag a little than to aim at making them grow in such a position; and by being kept dry at the root they multiply their feeders and acquire an amount of irritability which insures rapid progress when repotted in spring. We, therefore, recommend "AN OLD SUBSCRIBER" to give just water enough to prevent much flagging, and that will be very little indeed.

They should be looked over frequently, and all decaying leaves removed, and when the weather is mild and not foggy air should be admitted to the room. Unless they become very dusty it will be best not to moisten the foliage at all, as moisture is just one of the evils to be contended against. The best way of cleaning the leaves is to take a moderately moist sponge and wipe them with it. Geraniums in this hardy and dry condition will stand 2° or 3° of frost without injury, but it is not advisable to subject them to a lower temperature than 32°. At the same time they will be all the better in spring if never warmer than 40°

through the winter. As all cannot be set close to the window, the best way is to keep those which show the palest hue next the glass, or treat all alike in this point, letting them have time about in the best position.

With regard to the use of guano, in the case of *Geraniums* in a sitting-room there is no necessity for any artificial application of the sort. The power of plants to decompose ammonia depends on the amount of light to which they are exposed; and to apply any such stimulant to plants resting, as your *Geraniums* ought to be for the next three months, would be akin to the feasting of an individual, whose liver was clogged up and congested, with roast beef and brown stout. If you keep your young *Geraniums* cool, dry, and exposed to as much light as possible, these are the matters on which their hue and health depend.

All the fire that should be applied is just enough to prevent the temperature from falling below the freezing-point; and instead of vessels of water to keep the air moist, it should be kept as dry as possible, and when any of the leaves show signs of damp a fire might be kindled occasionally during drier weather.—D. THOMSON.

HARDY FERNS.

As certain diseases become epidemic, and many persons who had not hitherto suspected that they were in any way predisposed to them find out that such is the case, and oftentimes to their great trouble and danger; so in horticultural matters, diseases become epidemic there. Horticultural constitutions, which seemed at one time impenetrable to anything of this kind, are suddenly attacked. The eruption assumes a most violent form. The patient becomes restless, dissatisfied, evinces strong acquisitive tendencies, and is altogether a somewhat troublesome neighbour. His friends are sure to think him "daff." He talks either bad Latin, or declares his acquaintance with the highest aristocracy in the land—yea, even with royalty itself, and talks about the "Prince of Wales" and the "Princess" as if he were their confidential friend; indeed he, somewhat rude and personal in his remarks, has no hesitation in saying that the Prince is goggle-eyed or that the Princess "is weedy." I never believed, for instance, that I had the least tendency to Filicomania. I had cut many a peg, for layering *Carnations*, from Ferns, had waded through them in earlier days, when shooting had more charms for me than floriculture, but never, beyond admiring their feathery looks, gave them more than a passing glance; but when I had seen them petted and admired I felt that there was, there must have been, some predisposition in me towards them. The disease was increased by the kindness of some friends who gave me some to grow; and was materially aggravated by my friend Mr. Ivery, of Dorking, consigning to my care and protection some of the British varieties; and now with his and Mr. Sim's catalogue lying before me, I wish to say a few words to encourage the growth of our native species and varieties, of which we may say the name is now "Legion." Mr. Sim's catalogue comprising 315 species and varieties; Mr. Ivery's being more select, but still containing a goodly number. As to the mania itself, I think that it is uncommonly sensible, mainly because the charm of Ferns arises from form entirely independent of gaudy colouring. So much do I think of this, that few in my opinion can really study (I don't mean botanically), their varied and beautiful forms without having their taste improved, for correct taste has its foundation far more in the form than in colour. It is not the colouring of the old Etruscan vases or the Pompeian lamps that makes them so invaluable, but their correct and beautiful shapes; and when masses of colours, distinguishable at a great distance from their brilliancy, have become so much in vogue, I think it is well that colour should be toned down now and then by resting amidst the beautiful forms and livery verdancy of the fernery.

And now a word or two as to the fernery itself. I am not speaking of Fern-houses but of the hardy fernery. Of the two requisites for a perfect one I am, alas! unable to command one—viz., freedom from wind. Shade I can command to a certain extent, but the wind baffles me. It whisks into my narrow garden, twists the fronds all about, scorches the edges of the leaves, and destroys their beauty to a con-

siderable extent; so my best varieties must be grown in pots kept in a pit during winter, and under the friendly shade, not of a "wide-spreading Beech," but of a tiffany house; but still, withal, I try to keep up the semblance of a hardy fernery. This structure must be a matter of taste; and there is one rule that I think is worth while remembering—viz., Avoid everything that partakes of what is commonly called "cockneyism"—all shells, whitewashed flints, and such like abominations. Use good honest stones, or, what I think as suitable as anything, "burrs" from a brick-kiln. I suppose that all do not think so; for a good old friend and neighbour of mine, seeing my fernery in process of formation, asked "What I was doing with all that brick rubbish? Was I going to make a drain?" These materials have as ruinous an appearance as possible, and exposing the rough portions of the bricks to the outside, while convenient spaces should be left for the introduction of the Ferns. Some persons use roots of trees; but they breed such a quantity of fungi that they are, I think, very objectionable, though their appearance is very much in their favour. Any one who has seen the positions in which Ferns most delight to luxuriate will at once see that a light sandy soil is the most natural one for growing them in, and this must be compassed if possible in the fernery. I have tested the cocoa-nut refuse, and find it answer admirably. Mixed with an equal portion of peat and some silver sand, it forms to my mind the very best material for them. Where peat cannot be readily obtained leaf mould mixed with it would be an excellent substitute. The refuse retains a considerable amount of moisture without soddening, and the roots of the Ferns positively luxuriate in it. It is equally useful in the pot-culture of Ferns.

Some excellent remarks are made by Mr. Sim in his preface relating to the planting of the Ferns in the fernery, and I cannot do better than quote his own words:—"In arranging the plants generally, the evergreen and deciduous kinds should be so planted that when the foliage of the latter dies off for the winter, there may still be abundant objects of interest throughout the whole. To this end, pre-eminently valuable is the winter verdure of *Scelopendrium vulgare*, *Blechnum spicant*, *Polystichum aculeatum* and *P. angulare*, *Polypodium vulgare*, *Lastrea amula* and *L. dilatata*, *Lastrea Filix-mas*, and the very numerous, beautiful, and distinct varieties of most of these species."

And now what kinds would be most suitable for the purpose? Of this part I can only speak from my own limited experience; but having grown some of the species and varieties through Mr. Ivery's kindness, I will mention what seem to me most desirable; and, first, I would say, give place to royalty, and plant *Osmunda regalis* in a suitable and commanding position. In my own little spot I have a pipe which is supplied with water from the waterworks, and to this a fine rose, so that I can, whenever I like, have a miniature fountain at work. Close to this I have placed the *Osmunda*, which delights in a moist soil, and by slightly turning the tap there is, whenever the water is on, a continuous moisture, so that I hope my plant of it will flourish well if the cruel winds allow it to do so. Then we must have the Lady Fern (*Athyrium Filix-femina*), and some of its many beautiful varieties. Let me name a few out of the fifty-seven, which Mr. Sim places in his list.

apiculiforme, a curious and small-growing variety.
corymbiferum, handsome largish variety, with fronds from 1½ to 2 feet.
depauperatum, curious and distinct.
Fieldiae, a very remarkable and beautiful variety.
Frizelliae, a very elegant and curious sport.
laciniatum, remarkable lance-shaped fronds. A very pretty variety.
multifidum, the fronds are curiously and beautifully tasselled.
plumosum, a very graceful and beautiful Fern.
thyssanotum, very neat and pretty.
Of the Male Fern (*Lastrea Filix-mas*), itself very beautiful, there ought to be added the following:—
Bollandiae, a distinct and beautiful sort.
cristata, one of the very noblest and best of our British Ferns. It makes a fine head, and ought to be in every collection.

Of the common Polypody (*Polypodium vulgare*), there are also many varieties. Of these select
cambricum, the Welsh Polypody.
crenatum, a fine and stately variety.
marginatum, a curious and not by any means common Fern.
 Of *Polystichum angulare* there are also a large number of varieties—upwards of forty—and of these some must be had.
crisatum, a beautiful crested variety.
depauperatum, very small and curious.
proliferum *Woollastoni*, a most beautiful, slenderly-cut, and distinct Fern.

Others may be selected; and it must be borne in mind that the evergreen character of this Fern makes it a most desirable addition to the hardy fernery, and when used with the varieties of *Scolopendrium* it will impart a fresh appearance to it even during the depth of winter.

The *Blechnum spicatum*, or common Hard Fern, is also indispensable. Of the numerous varieties of it perhaps the most desirable are

imbricatum, a strikingly handsome and distinct variety.
ramosum, somewhat crested, and very beautiful.
Scolopendrium vulgare is another evergreen species, of which there are no less than seventy varieties, and of these several might be selected.
crispum, edged like a frill.
digitatum, a very beautiful crested variety.
marginatum, curious and handsome variety.
ramosum, exceedingly handsome.

Then there are other Ferns which may be added, such as *Woodsia ilvensis* and *Cystopteris fragilis*; nor would I be without the *Pteris aquilina*, the common Brake, from whence I have flushed in former days many a partridge, for its fine noble habit well entitles it to a place amongst its congeners; and others might be added as the fancy or pocket of the cultivator may suggest. I have not recommended rare species, or varieties merely curious in a botanical point of view, but such as I think would make a good beginning for a hardy fernery. I would, however, repeat what I have formerly said, that from what I know of our principal Fern-growers, any one may safely put himself into the hands of such men as Mr. Ivery and Mr. Sim, and if well inoculated I have no doubt that the virns will be sufficiently strong to spread, so that he will, by-and-by, be looking to add to his present small collection; or it may set him off at once upon the pursuit; and I am quite sure that the ladies of the family, if not altogether wedded to "King Croquet," will rejoice in the cool and fresh-looking appearance of the hardy fernery.—D., *Doat*.

P.S.—May I here correct an absurd sentence in my paper of last week on new Roses, arising from my wretched habit of fast writing? After enumerating the Tea Roses, I am made to say these all "succeed" well; it should have been "sound" well. There are other trifling little inaccuracies of grammar, to which not I but my bad writing must plead guilty. The note, too, on *Rose Reine de la Pape* ought to have been as a note to the paper, and not have been separated to another part of the Journal.

DEATH OF MR. DONALD BEATON.

It is very painful to us having to announce the death of MR. DONALD BEATON, which took place at his residence at Surbiton, Kingston-on-Thames, at seven o'clock on the evening of Saturday last, at the age of 62.

For a considerable time past, since his last illness, Mr. Beaton had been in an unusually good state of health, and had become as active and vivacious as ever he was in his best days. He was constantly engaged in attending to his plants and in reading up the latest horticultural information; but on Thursday evening last he was suddenly seized with an attack of paralysis, which entirely deprived him of the use of his left side, and from six o'clock on the morning of Friday till the time of his death he was perfectly insensible.

There are none who knew Mr. Beaton personally, and few who knew him only by his writings, who will not regret to hear of this event. For upwards of thirty years he was in the van of English horticulture, and for many years the leader of that branch of it which more immediately

concerns the flower garden. To Mr. Beaton we are mainly indebted for the direction that has been given to the modern style of English flower gardening, saving that part of it which is distinguished as "the polychrome style," and it is generally allowed that through his articles, as published periodically in the pages of this Journal, his fine taste and skill in the harmonising of colours have exercised an influence which has operated in all the best garden establishments in the country.

It was not in the practice of gardening alone that Mr. Beaton excelled. Although he has not taken a position among botanists, he was no mean proficient in that science, and there is, perhaps, not another example on record in the history of our British gardening of one who applied that science more skilfully and beneficially to the practice of horticulture. His knowledge of botany was not of that common order which consists in running over the names of plants; but whether on questions affecting the alliances, the structure, or the physiology of plants, he was equally acquainted with them all, and he possessed an originality of thought, a keen perception, and a strength of intellect that enabled him to step aside from many of the received opinions, and to promulgate views which some of the most eminent physiologists of the day were not slow to accept. Even as a botanist, however, his name will always be on record, the late Hon. and Rev. Dean Herbert, himself an accomplished botanist and one who could well appreciate the talents and worth of such a man as Mr. Beaton, having founded the genus *Beatonia* in honour of him.

As a friend Mr. Beaton was sincere, cordial, and constant; as a neighbour, generous, benevolent, and kind; and as a man, he exemplified, in all his relations in life, the strictest integrity, a scrupulous sense of honour, a forgiving disposition, and a charitable feeling to all with whom he was brought in contact. His playful humour, with which all our readers are so familiar, was perhaps the most prominent feature of his character, because it was that which he had the most frequent opportunity of exercising; but no other of the characteristics we have mentioned were less developed, although there were not the same opportunities for exhibiting them.

The Editors of this Journal feel acutely the final loss of their esteemed friend and fellow labourer. Fourteen years of daily intercourse knitted them and him closely together, and enabled them thoroughly to appreciate his sterling worth and to know full well the benefits they derived from his aid. In him they had an able coadjutor. And what though at times he was hasty in his assertions?—he was always hearty; if he chafed occasionally at opposition, in good time he made amends by proofs of his correctness or acknowledgment of his error; and he never depreciated the merits or undervalued the attainments of those who were students or labourers with him in the same field.

To the last he devoted himself to his favourite pursuits; he literally died in the midst of them, for it was when in the act of providing protection for his favourite flowers for the winter that he was seized by the disease which so soon proved fatal.

As soon as intelligence of Mr. Beaton's attack reached us, Dr. Hogg, whom he has left as his executor, and to whom he had previously entrusted the entire management of all his affairs, hastened to his house, but too late to receive from him a word of parting. The fatal symptoms had already set in; and, after two days of much apparent suffering and entire unconsciousness, our lamented friend breathed his last.

Mr. Beaton was a native of Urray in Ross-shire, where he was born on the 8th of March, 1802. For his portrait and a more detailed account of his career we must refer our readers to our Vol. 13, page 153.

GROUND VINERIES.

No more successful or interesting mode of growing Grapes in small gardens was ever invented than this. Black Hamburgh Grapes have ripened well in them as far north as Manchester; and Trentham Black and Black Hamburgh at Sawbridgeworth in Mr. Rivers's ground vineries.

It is a most remarkable fact that Vines trained on slates

under glass ridges, to which the above name is now applied, although never syringed or watered, never have red spider or oidium. For their immunity from the former the constant radiation of moisture from their "mother earth" sufficiently accounts; but why oidium does not visit them I cannot quite make out. These most simple of all vineries are now very common in the south of England, more particularly in Berkshire. A clergyman stated to me last season the almost-incredible fact that he had sold Grapes from his ground vineries to the amount of £20, which he had devoted to charitable purposes.—*Vitis*.

CONSERVATORY AND PALM-HOUSE CONNECTED WITH THE RESIDENCE.

I ENCLOSE a sketch of a conservatory and Palm-house I propose erecting, attached to a house I am now building. The drawing-room will open into the conservatory, 30 feet by 19, and 18 feet high, by two French windows, and the billiard-room into the Palm-house, 19 feet in the square. I have arranged the boiler-house so that the pipes pass under the billiard-room floor, so as to prevent injury to the table in cold weather. I wish to ask your opinion on the plan, and should be further obliged by your advice how to arrange the interior for the best. Also, what plants you would recommend, more especially for the Palm-house, which can, if necessary, have a height of from 30 to 35 feet.—*PERSEVERE*.

take a flow and return pipe right beneath the billiard-room floor on to near the west end of the Palm-house, and along to the north end of the conservatory, joining the flow and return there. If the pipes should be sunk enough below the billiard-room floor—say 3½ to 4 feet, then these main flow and returns could also be sunk beneath a path, out of sight, only by this arrangement there would always be a little heat in the conservatory when heat was not wanted in the Palm-house, and this with plenty of air would never do any harm. If deemed advisable, however, to keep all artificial heat from thence except when wanted, the pipes may go on as proposed, but a connecting bend should join the flow and return at the division between the houses, and a valve shut in the conservatory part would prevent the flow in that part when not needed. Keep in mind that this main flow-pipe should never fall from the time it leaves the boiler until it takes the bend to return thither. If that pipe at the north end of the conservatory is 3 inches higher than where it started from the boiler it will be better than if on a dead level; and at that highest point a small gas-pipe should be left open to prevent air accumulating, the open end of that pipe standing higher by a couple of feet than any other pipe in the house. From these two pipes other pipes can be taken to heat the houses, the one in the conservatory to be shut or opened with a valve.

5. The position of the pipes would much depend on the plan of arrangement. Such houses could not be kept at their best without other preparatory houses. Suppose, for instance, in the case of the conservatory, that you have some 18 or 24 inches next the drawing-room for steps, and then 3 feet of walk; the same in front of fruit-wall, some 18 inches in height, and a three-feet walk there, and two walks across opposite the two French windows; you would have a bed in the middle, and a bed at each end, and a bed or border in front and back. The common plan would be to take the pipes on the sides and ends, place a stage over them, a stage also in the middle, and supply with plants in pots in the usual manner. Now, if we wanted to make that conservatory an elegant affair, we would not have a pot seen, nor yet a pipe either. We would take two four-inch pipes right round the house (or three in front and north end, and two at back and south end would be better), and we would place them in a shallow trench beneath the pathway—the sides of pathway of stone, the centre over the pipes of iron grating to walk on. We would fix on as many places as we wanted for creepers—say, two at the back of the house, and six in front, preparing brick pits well drained for them, about 2 feet square, and as much in depth. We would have no stages at all, but would surround all the beds with kerbs of stone or slate 6 inches deep, and instead of planting-out the plants in the beds, we would plunge the pots in fine sandy soil, and cover with moss. All the inconsistency of glowing red pots and ill-assorted stages so near a drawing-room would thus be avoided, and the majority of the plants in the beds might be so managed as never to be much above the eye, but rather below it, whilst flaunting creepers and suspended baskets would amply fill up what space could be spared above head, so as to let plenty of light come in. What could be more beautiful in winter than a bed of Camellias fronted with Daphnes of kinds, and these with edgings of Hyacinths, Narcissus, Tulips, &c., and yet not a pot of them all seen to disfigure the chaste effect, with Acacias, and Habrothamnus, Passifloras, &c., depending from the roof? These creepers with a little rich mulching or manure-watering would grow strong enough, and the contracting of the roots in the small brick pit will cause them to bloom more freely than when the creepers are planted out in the house.

6. The same principle will apply to the Palm-house. A walk may go all round, and the pipes may here also be beneath the pathway; but if the same nicety need not be observed, the principal pipes might go under a wide shelf on the south side and west front. These shelves could then be supplied with stove flowering plants in pots, whilst the centre bed might be partly planted out, if such a plan were deemed advisable. If much were to be done in that way, as the bed in the centre would be about 10 feet square, it would much assist such plants as *Musa Cavendishii*, and others, if there were three four-inch pipes beneath the bed in which they were grown. Few Palms could be grown satisfactorily

[1. We believe that any of the builders who advertise in our columns would give you rough plans and specifications, and it is always best to have a clear understanding on these matters before commencing operations.

2. We see nothing objectionable in the position of the contemplated houses. We presume they will be span-roofed, or ridge-and-furrow-roofed, which will divide the rays of light more equally, as the main front of the houses will be to the west.

3. The position of the boiler is all right enough, provided you go deep enough down with it. The idea of taking the pipes beneath the billiard-room floor is good, but we notice that from the steps from the billiard-room into the proposed Palm-house, and the steps from the drawing-room into the conservatory, the floor of these places respectively will be from 18 to 24 inches below the level of the billiard-room floor, and, therefore, if the heating-pipes are merely to be on the surface of these houses, the flow and return must be sunk all that deeper under the floor of the billiard-room.

4. The simplest plan of heating such houses would be to

in such a house. Four pipes connected with the flow would be needed for top heat round the south and west ends, and one or two as returns, and joining the main return, could go round the division between the houses.

To make the most as to appearance, the beds should be arranged as in the conservatory, a pipe taken round beneath the warm borders, three beneath the central bed, and the plants planted-out, or seeming to be so from plunging the pots. That such attention to elegance is not often met with is just a reason why a man of taste should set the example. Then, likewise, the pipes for direct top heat would go beneath the pathway. One advantage this mode would have is, that no shelves or stages would be wanted. As in the conservatory, basket Orchids, trailing stove plants, and the climbers, would do all the work above head. Who will break in on the dismal monotony of shelves, and all the rest of it?—R. F.]

VINES IN POTS.

A FRIEND sent me packed three well-ripened Black Hamburgh Vines, seemingly only a year or two old (judging from the size of the wood), but as I have not much room, I would prefer them in pots. A line from you will meet my difficulties, which are—1st, Size of pot they will fruit in; 2nd, Soil; 3rd, When to prune.—A. G. J.

[If our correspondent had informed us whether he has received the Vines in the pots in which they have been grown and established themselves, or whether they are Vines that have been planted-out in a border for a time and then lifted, we would have had no difficulty in giving directions which would have met his case precisely. But as the Vines may have been received in either of the two conditions named, it will, therefore, be necessary to give directions bearing on both cases, in order that what shall be said in answer to the first question will meet the case. It would save a deal of perplexity and waste of words, if in such special cases more minute and explicit information were given as to the state of various plants and fruits about which information is required.

1st. If the Vines are in the pots in which they have been grown, it will not be necessary to repot them into pots of larger size, if those they are in are not less than 16's, or 10-inch pots. In the size named they will ripen a heavy crop of fruit, all other things being equal, with proper attention to watering and feeding with manure water. Presuming that they are now in pots not larger than the size named, they should not be shifted into larger pots at all, unless the Vines are wanted to fruit for several years in pots. In that case it will best to shift them into pots a size or two larger. And were it not from the danger of breaking their tender shoots, we would not shift them till they had developed a good many leaves, and had begun to make fresh roots, which, unless plunged in an unnaturally and injuriously strong bottom heat, they never do till they have made considerable growth.

In the hands of a novice it will, therefore, be safer to shift them just as the buds are beginning to swell in spring. The pots should be well drained; the soil used should consist of three parts turfy loam, and one part well-rotted manure, with a sprinkling of bone dust. The balls should be moderately damp when shifted, and the fresh soil should be rammed firmly round the ball in potting. A 12-inch or 14-inch pot will keep a Vine 6 or 8 feet long in a fruiting state for a good many years with proper feeding and rich top-dressings.

2nd. If the Vines have been received without pots or ball, as is just possible, the size of pot must be regulated by the object in view. If it be intended to keep them in pots for years, and the Vines are strong and well rooted, then put them into 14-inch pots at once. Drain the pots well, and use the same soil as already named. Distribute the roots nicely among the soil, and pot firmly. In this case there must not be so sanguine a hope of a crop next summer, unless the Vines are thoroughly well ripened, and a little bottom heat can be supplied when they begin to move in the spring. But even in this case, and with the best management, lifted Vines are apt to do what gardeners call "run," or "wire"—i.e., they show fruit well enough at first, but when the

stored-up sap is exhausted the bunches run away into claspers instead of being developed into bloom.

They should be pruned immediately, and kept in the coolest part of your greenhouse for the next three months at least.

The want of room is that which appears to have led to the determination of keeping the Vines in pots. But we would suggest and recommend, if the position of the greenhouse will admit of it, to make a border and plant one or two of the Vines out. They can be pruned and trained to occupy any desired amount of room, and will give far less trouble, and be much more likely to give better fruit, and more of it, than in pots.—D. T.]

STYLES OF GARDENING.

It is but natural that opinions should vary on almost every subject, and it is well that it is so, since without difference of opinion there would be no controversy; and as it is by controversy that useful facts are often elicited, I see no reason to fear a provocation of it, if the question at issue is likely to be of interest to those engaged in gardening pursuits. We have been favoured occasionally with various opinions as to the comparative merits of the old and new style of gardening, as regards the planting of flower-borders; but mere opinions, unsupported by statistics, do very little towards settling the question either way. What we want is a few old hands to give their experience and their views in a plain practical manner, divested of anything like prejudice, or even sentiment; for it is unquestionable that there is a great deal of the latter quality exhibited in the lucubrations of those who pursue gardening merely as a source of gratification and pleasure. The only correct estimate, I should think, is arrived at by the thoroughly experienced and practised gardener, who has served his time from his youth upwards, passed through every grade of his profession, and performed his full share of hard work both of hand and head, so that when a piece of workmanship is set before him, he is able to weigh both cause and consequence, and give an opinion at once both correct and impartial. Whether he would say that the old style is better than the new, or the new better than the old, is doubtful; but most probably he would take into consideration the progress of the times, and assert that as nothing in nature or art is stationary, it is little to be regretted that the old style of gardening has followed the natural course of things in general, and has passed, or is passing away; and if the new style does not possess such varied or agreeable features, it would be better to modify the old style, and adapt it to the times in which we live, than to indulge in vain regrets that what has passed away apparently possessed greater charms than what we have opportunities of more closely inspecting.

Having from my earliest boyhood been familiar with some of the old-fashioned border plants, and learned very early to distinguish such ones as the Spiderwort, the Catchfly the Soapwort, the Speedwell, the Livelong, the Bee Larkspur, the Bachelor's Buttons, the Golden Rod, the Starwort, the pretty Sun Rose, the Snapdragon, the Willow Herb, and many similar plants with their true English names, it is but natural that I should preserve some little regard for them. Still, viewing them in their true light as subjects for border planting, it is impossible to be blind to the fact, that among all the old border plants there is not one that I could name that gives the brilliancy of colouring, combined with the dwarf, compact habit, and continuous blooming of the ordinary bedding Geranium—that it would be impossible to find among them plants to supersede the common bedding plants of the day, and obtain from them such brilliant masses of colouring for four or five months continuously.

It is all very well for your sentimentalist to dream of the old-fashioned mixed border, where he might cull his Daffodils in March, his Wallflowers and Cowslips in April and May, his Pinks in June, his Cloves in July, Phloxes in August, perennial Asters in September, and Chrysanthemums in October and November. Certainly there is variety, every object has its peculiar interest. Each month also brings its own peculiar flora, and this to some persons

possesses great attraction; but there is not, and cannot be, that striking display of beauty which the bedding-out system presents. In this latter system the effect is sudden; it breaks full on the eye from the first, but if well managed the eye does not weary, for every bed, or part of a bed, will bear a separate inspection. There is much more in it than the mere gratification of the organs of sight, for the taste of the designer in handling the materials, the quality of the workmanship, &c., may all be discussed, and form as much a subject for comment as a painting or a piece of sculpture.

Now one of the chief objections to the bedding-out system put forward by its opponents is the sense of dreariness that is produced at the close of the year, when the shortening days show their natural effects on the masses of plants, or when an autumn frost changes the whole scene in a single night and necessitates their hasty removal, suddenly converting what were rich beds of flowering plants into a barren waste. I, for one, do not agree that this natural process, which has many analogies, ought to produce any such feeling. No sense of dreariness is produced at the approach of night after enjoying the light of the sun during the allotted time. Neither do we dread the approach of the time of rest after a day of toil. Nor do I see why the falling of the leaf should be suggestive of melancholy thoughts. When the trees have been clothed with verdure their allotted time winter itself comes and changes the whole aspect of nature, and by the contrast we are enabled to see tenfold the beauties that the summer brings forth—not that the winter leaves the garden entirely devoid of attractions. If it has been laid out and furnished with a view to winter as well as summer decoration, the change of seasons merely produces a relief, and leaves no cause for depression.

If we cannot have the gay flower-beds in winter, what can be more really beautiful than the habit and style of growth of many of the Coniferous trees? A judicious planting of these alone will give an interest to any garden. Evergreens of any description will make a garden look lively during the winter—that is, when they are well arranged; and the arrangement is, perhaps, the main point, for this alone will make all the difference between a mere mass or collection of shrubs and a scene calculated to excite interest. Again: I consider that, supposing the flower-beds to form the principal feature of the garden, and that they are duly proportioned and neatly made either on grass or on gravel, if kept neat and tidy when otherwise bare, there is nothing about them suggestive of barrenness, for they must always be associated with their summer occupants. In fact, an old gardener once told me that it was his decided opinion that at no time of the year did the garden look so well as when put in order for the winter. With the edges trimmed, the beds and borders turned up, the grass and gravel in the best possible order, not even the gaieties of summer made it more attractive. Without going quite so far as that, we may satisfy our minds that each season brings its own peculiar aspects, none of which need be dreary or unattractive, unless we are determined that one or the other shall be so. In this case the fault does not rest with the garden or the season. Then, again, there are ways and means of clothing the flower-beds with verdure during the winter, and of having spring flowers on the same ground that we expect to have summer and autumn gaiety. The method I have myself adopted has been effectual in securing this object. The process, I believe, is well known among gardeners, and has been objected to on account of the extra time and labour required, and the fact of few being able to appropriate a piece of reserve ground sufficient for the purpose. But as regards the time and labour, these are much less than are required by the bedding plants themselves; and as to the reserve ground, no garden ought to be laid out without some provision of the kind. It is as necessary to the garden as the scullery is to the dwelling-house, and quite as useful in the small garden as the large one. Besides, I happen to think that in gardening, as in other things, for every effect there must be an adequate cause. I would have our flower-beds as attractive in winter and spring as in summer and autumn. The labour and necessary appurtenances must be proportionate. There is this much to be said, however, that plants used for winter and spring decoration must be hardy, consequently they do not require to be protected in expensive structures.

But to the method referred to. Some spring-flowering evergreen herbaceous plants—as the white and yellow Alyssum, Cheiranthus Marshalli, Evergreen Candytuft, and above all Primroses and Polyanthus—are divided or propagated in August. They establish themselves before winter, and would flower the following spring, but are prevented. They are planted in the reserve ground a foot apart each way; and having one clear season and plenty of room to grow, they make fine large tufts for planting in the following October or November, having been in nursery quarters about fifteen months. When the bedding plants come off, the ground is dug and manured, and these herbaceous plants put in. Being large a few make a good show, and they may be placed 2 feet apart, so that a few dozen plants will crop a large space. Gardeners who understand these matters will see that this is very different to putting in little plants that must be set 6 inches apart to produce any effect. Plants raised in this way will often flower all the winter and most abundantly, even closing together with the quantity of bloom in April and May; after which they may be taken up and kept for stock, the ground being again manured for the summer bedders. It will be necessary to have two stocks of these plants—one for the current year's planting, and one to follow in its place. Cheiranthus Marshalli and Candytuft should be struck from cuttings early in the summer, to be ready to plant out in August. The others may be divided at that time, and planted for good until fit for bedding-out. By this process, which I will not deny takes up much time, the flower-borders and beds may be kept gay winter and summer; and those who are in a position to try it, need no longer complain of the dreariness brought on by the loss of the summer flowers.—F. CHITTY.

REVIEW.

The Scarcity of Home-grown Fruits in Great Britain. By CHARLES ROACH SMITH, Hon. Mem. R.S.L., &c.

WE do not know whether this suggestive pamphlet has been published; but it was read before the Historic Society of Lancashire and Cheshire, and the author has obliged us with a copy.

There are no two truths more certain than that "Nature intended that fruit and vegetables should constitute the chief support of man," and that in the British Islands "There is a great scarcity of fruit, and consequently it is high-priced."

That man was intended to be chiefly a vegetarian is demonstrated not only by his physical construction, but by the results to him of long deprivation from vegetable food. Scurvy among long-voyaging sailors is well known to be only preventible by a liberal supply of vegetable substances, either fresh or preserved, and Mr. Smith thus records another evidence:—

"Some years since the boys in Christ's Hospital were so infected with cutaneous diseases that they were compelled to be sent home; and so general and bad was the malady that a medical inquiry was instituted. The evil was proved to have resulted from the want of fruit and vegetable diet. Now, if a school such as this, richly endowed and watched over, is liable to be infected with loathsome disease from the absence of natural food, can we be surprised that millions of our fellow creatures, steeped in poverty and ignorance, and of improvident habits, are the victims of a neglect or misunderstanding of one of Nature's primary laws?"

That fruit and vegetables are scarce in our islands needs no further proof than a visit to and noting of the prices in the markets of London and other large towns. But go to the pettiest huckster and purchase the commonest of garden produce, and you will have to pay 2d. per lb. for Apples, and 8d. per dozen for Cabbages. This is a price which places them among luxuries seldom to be indulged in by the labouring classes, and these high prices are maintained despite the very large importations from France, Spain, and elsewhere by increased steam navigation. It is difficult, now that fruit is imported free of duty, to ascertain the quantities brought from abroad; but we are quite sure that those quantities are quadrupled since 1844;

yet from a return now before us we see that in that year duty was paid upon 182,590 bushels of Apples, 28,624 bushels of Chestnuts, 101,801 bushels of Nuts, 33,298 bushels of Walnuts, and on Grapes valued at £25,278.

That the deficiency and costliness of fruits and vegetables might be reduced admits of no doubt, and Mr. Smith thus points out some of the modes by which this most desirable result might be attained.

"If well-meaning noblemen and gentlemen, who take so much pains in constructing what are called 'model cottages' for labourers, would see that these labourers are industrious and provident, a well-stocked garden would be insisted on; but at present this grand accessory to the cottage, this vital source of half the year's subsistence, is left out of consideration, or it is made a matter of little consequence.

"There are enormous tracts of ground tenanted by thousands of persons less blessed than the class I have just alluded to, which, with just as much trouble as would be an amusement, might be cultivated, and would be cultivated if the masters of these men did their duty. The better-regulated French, even when encamped for a short time upon waste ground, will soon convert the waste into gardens, which occupy their leisure time, find them wholesome food, and keep them sober, cheerful, and contented. But in the districts of England to which I allude (take for example those of the brick-makers), squalor and wretchedness, drunkenness and high wages, go together. Neglected by their masters, who only look to the work to be done, their gardenless hovels are the picture of misery. Gaining wages enough to keep them with provident care through the winter, their only solace is the beer-shop; and for most of the winter months they subsist by begging or stealing, or live in the workhouse. I make no doubt that gardens would be books of instruction to them, and induce habits of foresight, industry, and sobriety, to which they are at present strangers.

"But how are we to provide Apples on an extensive scale to make them of general utility? Nothing is more easy. Be ever planting trees. I will give you a notion of what might have been done, and could yet be done, by the directors of our railways. Who will calculate the exact number of the thousands of miles of unoccupied land by the sides of our various lines? It is an easy task, and I here supply an estimate of what may be produced in a single mile. One mile would require about 250 trees, the cost of which, and the labour of planting, would be about £15. As good strong trees should be selected, in three years they would pay their expenses, and in a few years more we may calculate that out of the 250 about 200 would produce five bushels each, which, at 3s. per bushel would be £150; and, of course, if both sides of the mile of railway were planted the returns would be £300, and for one hundred miles we may calculate £30,000. But make yet a deduction for contingencies and the profit would be enormous. There is no reason, moreover, why our highways and byways should not be planted with fruit trees (especially the Apple), and also the vast tracts of land which surround hospitals, fortifications, and other public buildings.* One of the most absurd objections that has been opposed to my suggestion is that the fruit might be stolen. A highly intelligent friend of mine who keeps a large and respectable school, has, or had, a considerable space of unoccupied wall, the advantage of which for fruit trees I pointed out to him. He met my persuasion with the common objection—a fear of stealing. I observed, 'Your boys must eat something. Let them steal, or consider the fruit their own; and if you want any get up in the morning early and steal from them.' But where such large quantities of fruit as I contemplate would be grown, stealing to any extent need not be apprehended. How is it that in France we see the road-sides for miles lined with Apple trees? Is it that the French are more honest than we? If so, let us endeavour to rise to their standard of honesty."

Orcharding is now too much neglected, yet might most profitably be pursued, especially in the south of England

* Since writing the above I have had an opportunity of laying my views on this subject before the Chairman of the London, Chatham, and Dover Railway, and I have hopes that, in consequence, my suggestions will be, at least, partially adopted. If so, it is probable we may soon see the waste ground of our lines of railways yielding the shareholders a good profit from an unlooked-for source.

and Ireland; and we go further, now that glass and timber and other building materials are so cheap, for we know that they enable any one who will devote the money and time to the pursuit to grow the rarer fruits very profitably. We are acquainted with several persons who have erected very extensive orchard-houses, and sell the Black Hamburgh Grapes from them very remuneratively. We would go even further, and observe that in hundreds—nay, in thousands of instances, similar extensive glass structures might be erected against parts of some of our manufactories and heated by their waste steam or waste hot water. Such structures by ripening still earlier the Grapes and other fruits grown within them, would be proportionately more highly remunerative.

DRESSING FRUIT TREES WITH GISHURST COMPOUND.

As the season approaches when gardeners begin to think of winter-dressing their fruit trees, and as Mr. Rivers and other authorities have recommended the use of Gishurst compound for this purpose, I now ask permission to give the result of some trials with Gishurst on my trees last winter and spring.

For several years past all the orchard-house trees when fully at rest—say in December, have been drenched with a solution of Gishurst, eight ounces (8) to the gallon of soft water, without any after-washing with water. This occasionally caused a few buds from weakly trees to fall, but left more than sufficient for any crop, and made the trees look very healthy. However, last year I heard several accounts from thoroughly good authorities, of many buds having been destroyed, in some cases owing to too strong applications of Gishurst. I wished to test whether this had been caused by the dressing having been applied too late, when the trees were no longer at rest, so, when giving most of my trees their usual eight-ounce solution, I left a few for experiment later, when the buds should have begun to swell. Some of these were washed with eight-ounces strength of solution, and a few minutes afterwards the trees washed with water; others with four-ounces strength with no after-water-washing. The results were, that some buds were injured by the strong solution, notwithstanding the after-washing, which was not the case (except in the case of some half-dozen buds), with the weaker solution without water-washing.

The conclusions I have come to are, that eight-ounces solution to fairly strong trees thoroughly at rest is the best strength and safe for buds except, possibly, those of early Pears. That if this strength be applied after the wood begins to grow, some buds may be injured. That 4 ozs. to the gallon is safe even when buds have begun to swell, and is, perhaps, the best strength for not strong trees and Pears, especially early ones.

These remarks apply only to pot trees in orchard-houses, of which only I have any considerable experience. For fruit trees on walls I believe a pound to the gallon, drenched over the tree and wall by means of a plasterer's brush, to be the best strength. Last year I was allowed to experiment on some trees on an old wall, which year after year had been so eaten up with blight that their fruit came to nothing. I operated on three of the trees, Plums, with strong solutions of Gishurst, with the result that the trees so treated were much improved in appearance, and bore some fine fruit. The good summer may have helped, but they looked healthier than their unwashed neighbours, and now the whole wall has been abandoned to me to have a strong Gishurst treatment, the result of which I will communicate on a future occasion.—GEORGE WILSON, *Gishurst Cottage, Weybridge.*

AMMONIA IN AIR OF PLANT-HOUSES.—I quite agree with Mr. D. Thomson as to the beneficial effects produced by the introduction of ammonia into our forcing-houses. I have for several years been in the habit of using in the evaporating-troughs a small quantity of liquid manure from the farmyard. I have used it during the past season for Pines, Vines, Peaches, and Figs, and I consider it one of the best preventives against red spider.—J. CROSS, *Gardener to Lord Ashburton, the Grange, Alresford.*

TRENTHAM.

(Continued from page 328.)

The garden-house, in the Elizabethan style, is, for size, conveniences, and arrangements, what it ought to be for such a place. It is so situated that some windows will receive the full rays of the sun during the day—a great matter so far as health and cheerfulness are concerned. The sight of such a home ought to lead to the thorough relinquishing of all back sheds as residences, either for gardeners or their assistants. No rooms can be cheerful into

which the rays of the sun never penetrate. The walls are chiefly clothed with the Virginian Creeper. As already intimated, a wide piece of gravel with Ivy-beds separates the house from the range of houses to the west with its back buildings, the nearest of which to the house is the business office, followed by fruit-rooms, root-rooms, assistant gardeners' rooms, washing and bath-room, furnished with hot and cold water, &c.

Almost in a line with an eastern window of the dwelling-house is the back range of the upright Trentham-case, and farther southward is the front range. The space between these ranges on the west side, next the garden-house, is filled-in with a colonnade of three elegant stone or composition arches, and on a square block of stone is inscribed the name of Mr. Fleming, with the date of 1841, placed there by order of the late Duke, as a mark of respect and acknowledgment of the services of him, who for so long a period had been the presiding genius that devised and conducted so many improvements to such a successful termination. Between this colonnade of arches and the line of the garden-house, is a raised oblong bed filled chiefly with the white and purple Zelinda and the Yellow Titian Dahlias, all in bands and in full and massive bloom, and on a bank close at hand was a dazzling mass of the *Saponaria calabrica*, which is never more at home than when clambering over or dangling from a knoll. Here, too, was a cluster of raised Ivy-beds, the largest and highest in the centre, and surrounded with less ones, and all filled with *Geraniums* and centered with fine *Humeas*. Some of these beds appear in the engraving of the garden-house, close to which, after looking for each other in the early morning, we first had the pleasure of shaking

hands with our new friend Mr. Henderson, and receiving from him such an amount of courtesy and kindness as we could only barely expect from one, with whom in our boyish days "we had run about the braes," paddled in the same burn, knew all the same wondrous secrets about bird's nests, and quarrelled and fought only the more to cement our friendship as we carried our satchels to the same school.

Between that bank and beds on the east, and the end of the forcing-houses on the west, the main walk, from north to south, crosses the garden in a line with the garden-house porch; that walk extending beyond the south wall into what is called the nursery grounds, but which is the position for the famed ribbon-borders, &c., of which more anon. The sides of this walk are bordered with Ivy, about a foot in height, and rather more in width, which looked extremely well, especially as it was not close-trimmed. The sides beyond the Ivy were margined with Musk, Forget-me-not, Asters, &c., but the size of the fruit trees would prevent, if there were not other reasons, the close ribboning which they at one time received. Even now the quantity of bedding plants used must be most enormous. The sides of these walks are planted with Pear and Apple trees, trained umbrella or bell-shaped, and pyramidal or cylindrical-shaped

alternately, and all the trees seemed to be in the finest order and full of bloom-buds, from a regular system of stopping, though, from the frosts in May, the crop was much thinner than usual. All the lean-to houses, and some of the upright ones, are on the west side of this walk. Another walk nearly divides the garden from east to west, and has an arch thrown over it 10 feet in height, with a width at base of from 6 to 7 feet. This arched walk, now well filled with Pear and other fruit trees, must be a pleasant promenade in a hot summer's day, and the fruit can also be easily seen and examined.

By the side of other walks we found narrow arched trellises 2½ feet at base, and 5 feet in height, as we noticed at Keele the other week, and whole quarters filled with various devices as to training Apple and Pear trees, &c., with beautiful standard and pyramidal Currant and Gooseberry trees, that produce fine fruit, whilst the ground can be worked comfortably about them. Close to the Pine-ground vinery we noticed also two rows of upright Pear trees, that might be called rope-of-onion trees, being from 8 to 10 feet in height, and the branches or spurs not more than a foot through, and regular in width all the way. The appearance of the spurs indicated that by such training and good management a great quantity of good fruit could be obtained in little room.

With this glance at the kitchen garden we will accompany our readers through its ranges of glass houses, taking the east side first, and beginning with the upright Trentham-houses, in the back range, in line with Mr. Henderson's residence. This range consists of four houses, each 66 feet in length. As the ground rises to the eastern boundary, there are ramps with proportionate steps from one house to another, these ramps averaging 24 inches in depth, some being less, and some more. The whole of the upright houses are similar in size, and all are placed against walls. There can be no doubt as to the elegance of their appearance, and as little question that in the hands of Mr. Fleming, and now under the management of Mr. Henderson, they thoroughly answer the purpose, so far as plenty of good fruit is concerned. At first I believe they were chiefly intended for protection, as orchard-houses now are, but now they are mostly heated by hot water. They are all furnished with neat, narrow slate paths in the centre, are 6 feet in width, 10 feet high at back wall and front glass, the span-roof being about 15 inches higher at the apex, and one side of the span opens with lever rod. The upright front sashes are wide, with large squares of glass, and move easily behind each other by wheels running in a groove, so that abundance as well as little air in front may be given. In several of the houses there are also louver boards beneath the plate on which the sashes rest.

The back wall is covered with fruit trees trained either to a trellis, or oftener to nails as studs driven regularly into the wall. Trees are also planted in front, and trained to a trellis from 15 to 18 inches from the glass, and 4½ feet in

height. At that height it is found there is abundance of light to colour the fruit at the base of the back wall; in fact, Grapes in very shady places were exceedingly well coloured. Besides this upright trellis in front, an arch a foot in width is taken across from it to the back wall at every 12 feet, which gives these houses an elegant appearance as you look along them. It is also almost uniformly the case, that whatever the tree, Cherry, Plum, Peach, or Vine, these arches produce the very best fruit. The dotted line in the section will give some idea of these arches as we recollect them. Mr. Henderson has tried them nearer than 12 feet, but then he considered the back wall suffered. Having proved conclusively that the front trellis and these arches at 12 feet apart do no injury to the back wall, I would be glad if Mr. Henderson would set apart one house entirely to the front trellis, and arched all the way along to the back wall, which would then be useless for fruit, and report the result, not merely as to appearance, but as to the question of profit and loss, a matter which in all its bearings is nowhere more rigidly studied than in these gardens.

The outside borders of these houses, besides being drained, slope considerably to the walk. The first house is filled back and front with Plum trees, from which the fruit was all gathered in June; the short-jointed wood, the prominent well-swelled buds, and the leaves now turning yellow, being everything that could be desired. The second house was filled with Peach trees, the crop all gathered, this being the fourth house, and the wood getting in excellent order. The third house was a vinery. One rod is taken along the front at 4½ feet from the floor, and the bunches hang down from it, but the side shoots from the Vines help to fill up the space, and there is the arch across at 12 feet apart. At one end the front was thinly covered, and yet there were some huge bunches of the Marchioness of Hastings against the back wall. Against the wall were fine bunches of Lady Downes' as black as black could be, and there was also a fine crop of the White Tokay, which Mr. Henderson prefers much to the Trebbiano and Raisin de Calabre for late keeping, having frequently had it fine from late houses in April and the Lady Downes' in March. In this house the wood was strong, short-jointed, with large round prominent buds. The fourth house was devoted to Cherries, the leaves browning, the wood hard, and the buds strong and prominent; this house bore a heavy crop in April. On examining the short stubby shoots we found that nipping and stopping had very seldom been resorted to, the heavy crop having rendered such care and attention unnecessary. In these houses no part of the ground is ever seen all the winter, the bottom being filled with bedding plants; and there, until the houses are regulated for their respective crops, abundance of air can be given in mild weather, and a little heat in the pipes keeps them all right in winter. Even in this splendid place the most is made of every bit of glass at all times.

In the front range, beginning again at the west end, next to the garden residence, we come first to a Peach-house, the third in succession, from which all the fruit had been gathered. The next was an early vinery, also in a state of rest. The heating being insufficient, pipes were placed along the back as well as in front. The Vines at the west end of the house not doing so well as Mr. Henderson wished, owing chiefly, as he believed, to a great accumulation of moisture, the front ones were raised and planted in fresh material against the back wall. The outside border was removed, and well drained, and we saw the process going on for raising the border much higher than before. For this purpose the front pipes were elevated fully 20 inches higher. A slate was put down to separate the inside from the outside border, and prevent the roots in the meantime mingling together. Fresh Vines will be planted in the outside border, and when these are well established the inside border and the back pipes and floor will also be raised; and thus, whilst securing the best treatment for each, both back and front, the house will never be destitute of a crop. The third house was a Cherry-house; and here much the same method will be followed, as it is to be made into a late house for Lady Downes' Grape. The new border for the Vines is making in front in much the same way. The Vines will be left pretty much to themselves until established, so as not to have more heat than will suit the Cherries, so that a

crop may be had from the latter for a couple of years or so, when the Cherry trees will be removed either to another house or a wall, and the Vines be allowed to occupy the whole house. One great lesson to be learned at Trentham is, that nothing is done and no change effected without the matter having previously been looked at in all its bearings, and especially those having reference to economical and prudential considerations. The fourth house was a Peach-house, also empty, and having only this peculiarity—that the back wall was studded instead of trellised; and the trees at the back, instead of going merely to the top of the wall, were bent over at the top, so as to form a curve of 2 feet or so under the span roof.

We now step out, and find the west side of the east wall covered with Pears, and fronted also with these upright cases, but without any heat as far as we recollect. Here the crop was excellent, and the collection of Pears very fine, there being frequently many sorts on one tree and bearing profusely, as shoots with fruit-buds had been used frequently for grafting, and the scions were chiefly inserted on the sides of the main branches—a good plan, too, for rendering unfertile trees fertile. The only difficulty was in keeping the sorts distinct in the gathering. The fruit was much larger than usual, and some of them attain an extraordinary size under glass; but as a rule Mr. Henderson does not consider them quite equal in flavour to those grown on the open wall.

The north aspect of the south wall is appropriated to Cherries, Plums, &c., and the south side is covered with these upright cases from end to end, the length being from 630 to 640 feet. These are devoted to Peaches and Nectarines, and I think in part to Apricots, and at the end of August contained a great number of most excellent fruit, among which the Barrington and Walburton Admirable Peaches, and the Elruge and Pitmaston Orange Nectarine, were the most conspicuous for their size. Many splendid ones had been gathered for the Crystal Palace Show, on the 1st of September, where they stood in the first ranks of honour. Many fruit trees in pots are grown in front of these houses, where there is not a trellis.

In front of this fine wall is a large space of ground, even now called the "long nursery," but having nothing of the nursery about it, except the fact that thousands upon thousands of nursery bedding plants are turned out here every year to contend with the weather, and, if possible, thrive and show off all their perfections to the very best. The post of honour amongst these is assigned to two ribbon-borders about the same length as the wall—the one next the houses, and the other on the opposite side of a fine gravel walk between them. Beginning at the Box edging the back border is thus filled—3 inches from the Box is kept clear, then a foot wide of *Cerastium*, followed by Golden Chain, Scarlet Geranium, Feverfew, Trentham Rose Geranium, tall brown *Calceolarias* and *Pentstemons*, mixed; *Gladiolus*, in full bloom at the crest, the plants having been forwarded in pots; and then mixed Stocks, *Cineraria*, and an edging of *Thrift*. The opposite bed was in span-roofed shape, and thus the rows run from the Box:—*Cerastium*, *Lobelia speciosa*, *Manglesii* and Brilliant Geranium, mixed; Prince of Orange *Calceolaria*, and Purple Nosegay Geraniums, mixed, or alternate plants of each; tall brown *Calceolaria*, and Shrubland Rose *Petunia*, mixed, which made the centre row; the other side, skirted by grass, being just a counterpart of the above. The rains had lashed these borders very much, and the *Calceolarias* had been greatly injured; indeed, Mr. Henderson said they had not been quite up to the mark this autumn, but, nevertheless, the borders looked well, greatly enhanced by the beautiful walk, and the artistic manner in which the *Cerastium* was managed, regular and flat throughout, and yet nothing stiff about it, and greatly relieved by the three-inch space of dark earth between it and the green Box edging. If we had not seen these borders we might have left the *Cerastium* to come to the Box edging, but now we are convinced that the open space of 3 inches left, gives to the whole an artistic charm. Beyond, to the south of this front border, is a grass avenue, on which are placed oblong beds filled with flowering plants, the beds being edged alternately with Holly, Yew, *Berberis aquifolium*, and *Cotoneaster microphylla*. These beds are backed with groups of Hollyhocks, and these again by

massive shrubberies, through openings in which peeps are obtained of the pleasure ground scenery.—R. F.

(To be continued.)

GLADIOLUS.

I HAD not intended to add another word to this controversy, but as your correspondent somewhat appeals to me I must perform answer.

I. I did not say that derivatives followed the rule of the words from whence derived, but that diminutives did.

II. I did not intend to say in one place that the first syllable was glad and in another glade; but that as it was derived from *gladius*, I should throw the accent, whatever there was, on the first syllable.

III. I did not say it was a barbarism to say *Gladiolus*, but to make it *Gladius*, as if no "o" was in the word, which is Mr. Beaton's pronunciation.—D., *Doal*.

PROPAGATING VINES FROM EYES.

HAVING a wish to propagate Vines from eyes in the spring, would you favour me with your advice as to the best method of doing so? I have a vinery which I intend to start at the end of January, and a circular flue of fireclay runs up through the house. Would a pit made on the top of the furnace with 6 or 8 inches of sand or rubble stones at the bottom, with about 2 or 2½ feet of tan above the stones be a suitable place for the purpose?—D. P. B.

[The plan which you propose for striking your Vine-eyes would answer very well. There are, however, two or three evils which are likely to require being guarded against in forming a pit immediately over your furnace, by which it is presumed that the pit is proposed to be made over the part of the flue next the fireplace where the greatest heat is invariably to be found. In the first place, you must guard against too great an amount of heat, which would cause the buds to break weakly. The bottom heat, should not exceed 80°. A thermometer plunged in the tan will, therefore, be necessary. It is also to be feared that the position of the pit which you propose forming will be too far from the glass, which in conjunction with a high bottom heat would be the very worst position possible for Vine-eyes after they had broken into growth. But if you can raise your pit so as to be within a couple of feet or so of the glass and not under the shade of other Vines, your plan with ordinary attention will do very well.]

We do not, however, consider bottom heat an indispensable requisite in raising young Vines from eyes, and never practise it ourselves unless when very early ripened Vines are the object, and which, of course, requires that they be pushed on rapidly early in the season. In ordinary cases the method we adopt with success is, to put the eyes to the number of about thirty into an eight-inch pot well drained and filled with equal parts of loam, leaf-mould, and sand. The pots are then placed on a shelf near the glass in a vinery, which is to be started in February. Here they just get the temperature which is usual in starting established Vines, and they always break strongly and do well. As soon as they have made roots about 2 inches in length they are potted-off into four-inch pots, using a compost composed of half loam and half leaf-mould. We prefer potting them off thus early, as there is less danger of their receiving a check by the roots being broken in potting-off; and they are put into eight-inch pots at first to save trouble in watering, crocking pots, &c., which when they are put singly into small pots is required to a greater extent.

If convenient we put them into a little bottom heat after potting them off, but are not very particular on this point if we can place them near the glass in any light structure where the night temperature ranges from 65° to 70°. In a bottom heat of 80° they will, however, come into growth sooner than otherwise; but Vines should not under any circumstances be left longer in strong bottom heat than is just necessary to give them a start after being potted-off. From this it will be inferred that the pit proposed is not necessary, and if far from the glass, would, therefore, be objectionable, and that, if a shelf in the warm end of the vinery near the

glass is available, or can be put up, bottom heat is not considered necessary unless when it is desirable to push on Vines early in the season, with the view of ripening them early for the purpose of early forcing in the following season.

To grow your Vines well after they are well rooted in four-inch pots, shift them into eight-inch pots, and keep them in a light place with a night temperature, after the middle of May, of 70°, with a moderately moist atmosphere. If required for planting purposes as permanent Vines, eight-inch pots are quite large enough, a well-ripened cane with plenty of fibry healthy roots being what is required, and not thickness of growth. For fruiting in pots they should be shifted into 12-inch pots, in which with feeding by liquid manure they will make splendid canes.—D. T.]

SOME GARDENS WORTH SEEING.

DURHAM.			
Name.	Proprietor.	Gardener.	Station.
Grindon Hall	John T. Alcock, Esq.	Mr. J. Archer	Sunderland.
Ashburn	E. Backhouse, Esq.	Mr. Hardey	Sunderland.
Undercliffe	James Allison, Esq.	Mr. J. Cain	Sunderland.

SALE OF CHINESE PLANTS.—The following prices were realised at the sale at Mr. Stevens's on Tuesday and Wednesday last. *Abies Kämpferi* from 10s. to £1 10s. each; *Woodwardia orientalis*, 15s. Lots of six *Pinus Bungeana* brought from 11s. to 17s. per lot, of *Bambusa variegata* 19s. and £1, of *Torreya grandis* 5s. to 19s.; of twenty-five *Chamærops Fortunei* 9s. to £1; of twelve *Lastrea opaca* and *atrata* 10s. and 11s.; of ten *Deutzia crenata flore pleno* 6s. to 9s.; similar lots of *Iris laevigata* 5s. to 9s.; of five *Woodwardia japonica* 11s.; and of twelve *Lonicera aureo-reticulata* 5s. to 7s. per lot. Altogether the proceeds of the two days' sale amounted to upwards of £350.

WORK FOR THE WEEK.

KITCHEN GARDEN.

KEEP the heaps of compost well turned over, as the time is approaching when every advantage must be taken of frosty mornings to wheel it over the land. As a general rule, ground that is very deeply trenched should be manured after the trenching, and the manure forked in, except in the case of tap-rooted plants, which will require the manure to be trenched in at the bottom, and not incorporated with the surface soil. *Cabbage*, earth-up those planted for Coleworts, for winter and early spring use. Look over the principal plantations frequently to see if slugs attack the plants; if they are numerous lay a quantity of *Cabbage* leaves on the ground, and examine them daily; a pail of hot water or some lime may be taken round at the time they are examined, and slugs shaken into it; thus many thousands may be destroyed at this season. *Celery*, earth-up that intended for winter use a good height. As soon as the soil becomes a little dry it will be necessary to attend to this as early as an opportunity offers, as the frost may set in shortly and do much mischief. *Endive*, continue to blanch it by tying up. *Potatoes*, the whole of the main crop should now be taken up and carefully stowed away. *Peas*, a few of these, and also Broad Beans, may be sown in a warm, dry part of the garden. If any esculent roots, such as Beet, Carrots, *Scorzonera*, *Salsafy*, &c., remain in the ground they should be taken up immediately. Dress *Asparagus*-beds; manure, trench, or ridge all vacant ground, bearing in mind the spring crops, for which each portion of the ground is to be prepared.

FLOWER GARDEN.

During the present month more than common attention is required to preserve this department from the desolating

effects of the weather, when the sweeping-up and cleaning of one day may be effaced by the storms of the next. Badly-drained or ill-constructed walks will suffer from depositions of mud, which should be corrected as soon as possible to allow of what may be called the enjoyment of fresh air and exercise in favourable weather. The weather is still favourable for executing alterations, and where these are in hand they should be prosecuted with the greatest possible dispatch. Planting and the removal of large evergreens cannot be finished too soon, for it is of the utmost importance that the plants should be afforded some chance of making fresh roots before the trying winds of March. See to small plants as well as large being secured against wind, for these are often greatly injured by being blown about after planting, which a small stake and a few minutes' work would prevent. Those who purpose making additions to their collection of Roses should do so at once, as there will be a better chance of obtaining good plants now than after the nursery stock has been repeatedly picked over. The present season is also very favourable for planting all but tender sorts, which had better be kept under glass until next May. In preparing ground for Roses, let it be trenched at least 2 feet deep, and let a heavy dressing of manure be well incorporated with the soil to the full depth. It is hardly possible to make the soil too rich for any kind of Rose, particularly the autumn-blooming kinds. Look over the herbaceous borders, and make any alterations that may be intended there, taking up and dividing any of the coarse-growing plants that may be inclined to encroach too much upon their neighbours. The modern system of gardening is fast driving this class of plants out of cultivation, but many of them are really beautiful, and if they were more largely grown many gardens would not have that naked appearance in spring which is too often seen. Sweep and roll grass frequently, and keep gravel walks hard and smooth by frequent rollings.

FRUIT GARDEN.

Let there be no lack of attention in the fruit-room at present, and during the first few weeks after gathering more is required than all the season afterwards. Give just sufficient air to carry off the damp, but nothing more, as allowing dry winds to blow over the fruit would only cause shrivelling. Strawberries for early forcing to be placed where they can be protected from drenching rains. Proceed with former directions as regards planting-out fruit trees of all sorts. Cast an eye over the trees in the orchard, and see if there is a necessity for the judicious thinning-out of the branches.

GREENHOUSE AND CONSERVATORY.

Chrysanthemums will now require abundance of air, with a liberal supply of manure water. Great care to be taken never to allow them to flag for want of water. Look over the plants frequently, such as *Leschenaultias*, *Boronias*, &c., that are liable to suffer from damp and mildew. Keep *Cinerarias*, and other softwooded stock clear of green fly, and endeavour to secure stocky plants, by affording them sufficient pot-room, and admitting fresh air freely whenever the weather permits. If such things as *Geraniums*, *Cinerarias*, and herbaceous *Calceolarias* must be wintered in the same house as the Heaths and other hardwooded plants, they should be kept as much as possible by themselves, as they will require a somewhat closer temperature than hardwooded plants; but where circumstances admit of it, these should occupy a house or pit by themselves. *Cinerarias* and *Geraniums* intended for late blooming will do very well in a cold pit, if the weather should not prove very severe, but those intended for blooming early should be placed at once where fire heat can be used at will, so as to be able to preserve the foliage from damp. Roses for early forcing should be pruned by this time, and placed where they will at least be free from heavy rains. Where American and other shrubs are used for forcing, these should be taken up and potted without delay, placing them in a cold pit until they are wanted for forcing, or in a turf-pit, where they can be protected from severe weather by straw mats or other coverings.

PITS AND FRAMES.

All flower-garden plants, such as *Petunias*, *Verbenas*, *Calceolarias*, &c., intended to be wintered in cold frames or pits should now have strict attention. Let the supply of

water be limited to that quantity only which is requisite to keep them from flagging, and let them be frequently gone over, and all dead leaves removed. Give them all the air possible during the day, if dry, and shut up tolerably early in the afternoon. Finish potting Dutch bulbs if not already done.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

For general details in all departments we would refer to last and previous weeks, as the work has chiefly been of a routine character. One object of importance now is to secure

SALADING FOR THE WINTER.

For this purpose half or three-parts-grown Cabbage Lettuce should be taken up with good balls and planted about 10 inches apart, so that the air can pass freely between them, in cold pits or frames. There they should have air given liberally every day, and the glasses left off in fine days, and air given at night, except in frosty weather. The harder they are kept and the drier the atmosphere in the muggy weather of winter the better will the plants do, and the more free will they be from everything like mildew. For this purpose, in transplanting them, place them in trenches, water pretty well at the root, and cover up so as to have dry earth on the surface. To help this still more, burnt clay or dry charred refuse may with much advantage be strewn between the plants after planting. Last season we noticed a clever young man drenching such a planted bed, by sending a stream over it from the rose of a watering-pot, held at least a yard above the plants. We were not surprised to learn that most of the plants rotted or mildewed, and, of course, it was a misfortune, but no one was to be blamed.

Endive will stand well in ordinary winters on sloping banks. In fact, the best for standing we ever had was planted on ridges 2½ feet apart, the plants inserted on the top of the ridge. A few leaves or a little rough hay not only blanches them, but keeps out the frost. On the top of these ridges and on sloping banks with the surface stirred, Endive in general winters will stand green until spring, ready then to be blanched. To make sure, however, a lot of plants not quite full grown should be taken up with balls and planted thickly under protection. Where glass cannot be had, straw, cloth, canvass, and wooden covers, such as those used at Keele Hall and Trentham for borders, &c., answer remarkably well, as they can be moved off in fine weather; and the covers especially, even when the weather is unsettled, may be elevated in front, or even back and front, and allow air and light too to pass freely beneath them. For all such purposes we would prefer wooden covers if we could obtain them. It is now getting on for twenty years since we recommended them to a gentleman of very refined taste, who abominated the litter from mats and even straw covers, and we lately saw them very little the worse for the wear and tear they had undergone. They were made of three-quarter-inch best deal, with three cross-pieces beneath, and a ledge 1 inch deep all round, to rest on the back and the rafters between lights, as they were previously used for covering pits and frames, but they came in for all kinds of protection. As far as we recollect, they were 6½ feet by 4, well painted and neatly finished, and cost altogether about 7s. each—a good outlay at first; but they were neat, and to secure the same protection from mats would have cost about as much in ten years, and nothing to look at but tatters, instead of a nice cover as good as ever.

Chicory also makes an excellent salad, and when left in the ground should have some branches laid over it, to be covered with straw in severe weather, in case there should be a difficulty in taking it up, or the roots may be taken up and packed closely in earth until they are wanted. A good plan to get it quickly is to fill a 12-inch pot with good roots—say eight or ten, water well, set the pot in a warm dark place, or in any warm place provided you place an empty similar-sized pot over it, daub round at the junction with clay putty, and daub up all the holes securely to exclude light, and cut when the yellow leaves are not more than 6 or 7 inches long. For a regular supply no plan is neater or better than using a narrow barrel or upright box, with holes three-quarters of an inch in diameter in layers 4 inches apart all round. Place

the plants in layers in the barrel or box, packing with earth and giving a little water as you go on, merely leaving the crowns of the plants or roots outside the holes, and then place the box in a dark cellar, and, just as in the above case, cut before the leaves grow too long. Six inches is a good size, if longer they become drawn and insipid. When hard driven we have taken up Dandelion roots, where we knew they grew strong, by the sides of a highway, and but for size think them quite as good as the Chicory. Our own impression is, that the Chicory is a shade the better of the two, that Endive is better than either, and a good Lettuce best of all.

Where Rampion is much esteemed, a parcel of roots should be taken up and packed in sand ready for use. Took means to protect Radishes, and will sow a bed under glass with a slight bottom heat, as about the new year these will be more tender than those sown in autumn, however protected. Nothing is better than Wood's Early Frame, though every district has its own peculiar favourite kind. The smaller the tops, other requisites being equal, the better the variety, as thus great quantities can be obtained in little space. After the seedlings appear, the plants cannot have too much air in favourable weather. If kept close they will come with long unsightly necks. In most families Beetroot is relished when of a middling instead of a large size. It will grow to little more advantage now, and therefore should be taken up before frosted. In taking up, use strong forks, so as not to break a fibre if possible, and merely twist off the long leaves from the crown. It must also be boiled in that state, as the smallest incision is fatal to everything like quality. A great object in most establishments during winter is a good supply of small salading, but for what reason we know not. We have not been required to do much in this way for some time, but it is one of those matters in which it is easy to commence and have a good supply in a short time, as nothing but the seed-leaves and the smaller finer leaves alone are used, such as Mustard Cress, American Cress, Rape, &c. These may all be grown freely where there is protection from frost; but, on the whole, small narrow boxes—say 2 feet in length, 4 inches deep, and 4 inches wide—are as good as any. Small four-inch pots are also very good. These should be half filled with roughish leaf mould and loam, and filled up to within an eighth of an inch of the top with sandy loam and leaf mould pressed level, the seeds sown thickly, pressed level on the mould, watered, and set in a dark place, or covered with a cloth or paper. We have dusted the seed with a little sand, but it makes the seedlings hard to wash. When the seeds are merely pressed level on the surface, and not pressed into the soil, the seedlings rise clear and free from grit, and in most cases water would injure rather than help them. We think, too, that when served separately, the salading will look best with the leaves all one way, instead of the head and heel way, in which it is generally presented.

We suppose we must finish with Celery. We have not, since the end of August, taken up a single head but what has been in first-rate order for the table for cheese or salading. Not one head has been run or hurt in any way. From what we said formerly, we have had several private letters complaining of the Celery bolting and running, and being diseased, &c., and one or two, in badinage we presume, ask how much it would cost to buy the secret of preventing early Celery from bolting. Well, as to secrets, nobody that wants a secret kept about gardening should tell us about it, for, if it is worth being made known, we are sure to tell everything about it. Years ago, and more recently, we have stated everything we knew about the matter, and may repeat all again in time for next season, as the reasons would not apply now. Took the opportunity of dry days to add a little more earth to the plants in beds. We have no objection to bit-by-bit earthing-up now, but we would none of it in August and September. In stiff soils, instead of earthing-up very high, it is better to have some stubble or tree leaves placed lightly between the plants, as that lets the air in and keeps the light out. The leaves should have a little litter over them. Put a few Potatoes in small pots to forward them.

FRUIT GARDEN.

As already referred to in late Numbers, no time should be lost in lifting, transplanting, root-pruning, or making fresh

plantations of fruit trees. The modes have frequently been alluded to. Forked over some rows of Strawberries that were not previously done, not going deep, however, but merely loosening the surface for 2 or 3 inches. Prefer the steel forks for this purpose far before any hoeing. Pruned fruit trees as we could get at them, opening up the centre and cutting back some large branches that had become bare of buds below. Painted and tied out of the way Vines in pit that had been pruned some time. The paint was chiefly sulphur, clay, and cowdung. The sooner such work is done the better, as the longer the stems are thus covered the more likely are all eggs, &c., to be smothered. As already intimated, those starting Vines now must use heat moderately and moisture abundantly.

Pruned and washed with hot water and soap trees in early Peach-house, now exposed. Washed all the walls and woodwork with hot soap-water, and painted the trees with a paint made of tobacco-water, soft soap, sulphur, soot, lime, and cowdung. The tobacco, half a pound, with half a pound of soft soap, a quarter of a pound of glue well boiled in two gallons of water, equal portions of sulphur, soot, and lime, were made into a paste, and about double portions of clay and cowdung added. These quantities made in all about four gallons of mixture, which from experience we find will stick well. We would have preferred the trees being frosted before painting them, and for that purpose we slightly syringed them before dark on nights when we expected frost, but we did not get enough to ice or freeze the moisture outside of the trees. We think that this freezing is capital for destroying insects; but we must wait no longer, as we want the floor of the Peach-house for storing lots of Geranium cuttings just struck, and we want the places in which they are for other things. Before placing these on the floor in boxes we will remove a couple of inches or so of the surface soil, fork-up, water with hot water, and then give a layer of cowdung, covered over with fresh mould. All the woodwork of trellis, &c., will be done with quicklime. Into such a place Ageratum, Amplexicaulis Calceolarias, and Heliotropes should be put, as they will not stand much frost, and are better if not below 35°.

We at one time used to commence our first Peach-house early in November; but now we let it come on in the spring naturally, and, as the trees are used to it, they generally break early enough without any heat except excluding frost, to bring the fruit in in June or the end of May. With sharp eyes and glasses to help them, we could discover no insect on the trees, scale or anything else; but there were many little scaly pieces on the back wall where the whitewashing, &c., had peeled off, and underneath these we found traces of insects and eggs too: hence the importance of scraping off all these scaly pieces and giving a good washing with hot lime considerably darkened, as the lime itself would be too white and reflect the heat and light too much. A little lampblack, pounded and made into a paste, will go a great way in this direction. Painted also the hot-water pipes we could get at, using for this purpose lamp-black, oil, and some whitelead to give body. In all houses where much heat is wanted, this painting of the pipes should be given in time, that they may be well dried and sweet before there is much heat in the pipes. Nothing is more unpleasant than to go into a house and be next to knocked down by such an effluvia, and plants like it as badly as ladies do. This painting is more required for preserving the pipes when sulphur is much used in forcing or during growth.

Picked out a few berries from Grapes that were damping, and these should be looked to every day, as if one affected berry is left there will soon be three, and ere long half a dozen, so quickly does the damp spread. Have a brisk fire now once every day, and air on to keep the atmosphere dry, and if the house is shut up at night let the fire out. As yet we have never been without air at night in these late houses: that air has chiefly been at the top of the back wall. Many experiments tend to show that there are a great many misconceptions as to the circulation of air. No doubt it is good to have it all over the house, heated before it enters by passing over pipes; but we are satisfied that outlets at the highest points in lean-to-houses will soon cause a circulation in all the confined space.

ORNAMENTAL DEPARTMENT.

We meant to say something about greenhouse stoves, but

would willingly request our readers to study what Mr. Keane says at page 335. When we used to force hardy shrubs we liked to pot them in spring, plunge them, mulch them, and properly water them all the summer. We have, however, done Lilacs, Rhododendrons, Roses, &c. in good style by now selecting plants standing thin with good buds. We took them up carefully, with balls if possible, and squeezed them into as small pots as they could be put into, using suitable soil and firming it well, and then plunged them out of doors into a slight hotbed of litter and leaves, covering the surface of the pots too, where the roots would have a temperature of from 60° to 75° and 80°. In a month or six weeks they might be taken into a house with a little bottom heat, and the extra fillip to the roots caused the flowers to come strong and vigorous. Our out-door work much as last week. We have spoiled some of our best flower-beds by taking away the centres of pyramids, as we were afraid of frost. Among the best of these were fine plants of Cassia corymbosa, a dense mass of orange from bottom to top. We once tried them turned out in pots, but they gave no such massive corymbs of flowers as when planted out. We have also taken up a lot of Geraniums, and as we could not pot them or give them any fire heat, we pruned them well back to the hard wood, cutting off all the soft part, dipped the head in lime, and now we are packing them as thick as possible in a cold pit. We give a little water at the roots as we go along and firm the earth about them, and when done will throw a lot of charred and burned earth over them, say 2 inches. We shall be satisfied if these do not show a green leaf until the beginning of March.—R. F.

COVENT GARDEN MARKET.—Oct. 31.

The supply this morning was fair, but not so heavy as we have lately had to report; still it was quite sufficient to meet all requirements. Crassane Pears are now coming in; and in Apples Cox's Orange Pippin, King of the Pippins, Ribston Pippin, and Golden Pippin afford the best samples. Keutish Cobs are bringing 65s. per 100 lbs., the very finest 70s.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Roses, Fruit Trees, Conifers, Trees, Shrubs, &c.* 1863-64.

B. S. Williams, Paradise and Victoria Nurseries, Holloway.—*Catalogue of New and Choice Pelargoniums—Select List of Gladioli.*

TO CORRESPONDENTS.

AZALEA INDICA (*Subscriber, Liverpool*).—You will find such directions as you require in the "Cottage Gardener's Dictionary;" and a good article by Mr. Fish in No. 613 of our First Series.

LEADEN PIPES (*A. Z.*).—Our correspondent wishes to know where he can obtain leaden pipes coated inside and outside with sulphate of potassium.

BOOKS (*A. B. C.*).—Glendinning's "Practical Hints on Culture of the Fine Apple" (Longman & Co.), Hentrey's "Rudiments of Botany." (*Constant Reader, Bristol*).—Sanders on the Vine.

DIELYTRA CUCULLARIA (A. R.).—This plant was introduced so far back as 1731 under the name of *Fumaria cucullaria*. It is figured in Curtis's "Botanical Magazine," t. 1127. It was in cultivation in 1810 as *Fumaria cucullaria*, and was commonly grown under that name when old-fashioned herbaceous border plants were in vogue. You are quite right in stating that it is scarce, but you will see from the above that it is no novelty, though the flowers are very singular. In the United States of America it is vulgarly known as "The Dutchman's Breeches," on account of the two horns at the base of the flower. In the open border it usually grows about 9 inches to 1 foot high, but, in poor soils it does not exceed 6 inches in height. When growing in very poor soil the flowers are nearly white, in stronger soil they are of a yellowish-pink, and when grown in loam and peat the flowers are of a delicate pink. We have seen it flowering beautifully in June planted in an ordinary herbaceous border, the soil being light, and rather sandy loam. We think your plant will prove to be *Dielytra eximia* (Corydalis *eximia* and *Fumaria eximia* of some), which is a very pretty plant with flesh-coloured flowers in June or July, growing $\frac{1}{2}$ ft. high. The close atmosphere of a cold frame will induce growth, but that free exposure to sun and air will be lacking, which is necessary to the ripening of the underground parts, on the thorough ripening of which depends the flowering stems appearing the following spring. If you turn your plant out in a sunny border, in poor rather than rich soil, we think you will be satisfied with the result. If on the other hand you desire to keep it in a pot, drain well, and use a compost of sandy peat half, light loam a quarter, and silver sand the remainder, placing the bulbs or roots a couple of inches below the surface. Water freely whilst the plant is growing, but after growth is completed gradually diminish the supply, and place the pot in the full sun, plunging it, however, to prevent the roots being dried up. Give no water after August, and keep dry rather than wet during the winter. With this treatment we think you will have no difficulty in blooming it, and if you succeed, we will thank you for a flower, for we are particularly fond of rare and curious plants.

HARDY AQUATICS (W. Robinson).—I regret to say the aquatics named by him are only to be had at some botanic garden. They were and probably are in some of the botanic gardens, Kew being the most likely place at which to obtain them.—GEORGE ABBEY.

CONSERVATORY FLOOR GREEN (Flora).—Dissolve 1 lb. of soda in 3 gallons of boiling water and pour it boiling upon the white stone floor. Scrub it thoroughly whilst wet with a scrubbing-brush, and then wash clean. If any green remains, wet the floor with soda water as before, and rub with pumice-stone until thoroughly clean.

RANUNCULUS CULTURE (J. S.).—Leave them in the soil, for it is too late to take them up now that they have made shoots an inch in length. Cover the beds with an inch of fresh soil, and your beds will take no harm. In future years take up immediately the foliage turns yellow, and store away in boxes in a cool dry place. Your other query shall have a reply as soon as we obtain some information promised to us.

WALTONIAN CASE (Amateur).—We do not know where this can now be seen except at its inventor's, J. Walton, Esq., a solicitor residing at Kingston-on-Thames. Of course no one would intrude upon him without permission.

EVERGREENS (E. C.).—There is no book devoted to the cultivation of Evergreens. The "Cottage Gardener's Dictionary" gives such directions, but it includes other gardening subjects. Your soil or subsoil must be very clayey or otherwise unfertile to kill "all your evergreens."

HEATING A MELON-HOUSE (A Reader).—To have early Melons, and early Melons in a house 15 feet by 11, you may, as you propose, have two beds on each side, which, after allowing 4 inches for the walls at the pathway, will each be 3 feet 8 inches in width—ample width enough for anything. Beneath each of these beds you should have two three-inch pipes to heat separately; or, to save expense, they may go right round and thus heat both beds at once. Then you had better have two three-inch pipes on each side for top heat, and these should be supplied with evaporating-pans. The bottom pipes should be so placed that after surrounding them with 6 or 8 inches of rubble there would be room for 15 to 18 inches of soil. We do not know the elevation of the house or we might counsel more. In such a short length we think you are right in having Cucumbers at back and Melons at front, and we presume both are to be trained to a trellis. But if the house had been 20 to 30 feet in length we would have proposed devoting one-half of the house to Melons and the other half to Cucumbers for reasons frequently given. We do not think you would do any good with Figs in such a house along with the Cucumbers, &c.; but if there is room enough above you might grow the Figs in both beds either in tubs or pots, or, what we would much prefer, with plenty of drainage and a foot or 15 inches of soil, and the plants turned out in the beds. You would need then no pipes for bottom heat, and to have Figs moderately early two four-inch pipes would be enough for top heat. To have them early, say in May, you would need three, or better say four of such pipes. Then you would get Figs from May to November. If you give more particulars we may be able to give further help.

LILY OF THE VALLEY DWINDLING (D.).—Either now or in spring just as the buds begin to move, take up the plants, divide them carefully into lumps about the size of your hand and plant carefully in well-moved soil, and with some rotten leaf mould in it. That will give size to the leaves and flower-stems. If the soil is light, hum it as much as possible among the fresh plants, and top-dress with rotten dung. It would be as well, however, to leave a piece not taken up, but remove the leaves, and cover with 6 inches of rotten dung, through which the rains of winter will penetrate. In March rake this off, leaving only 2 inches of the most rotten. If you wished a few early flowers, you could select the most promising buds and fill a few pots with them as thick as you could cram them. Were the plants ours we would prefer moving them now. We would prefer the piece planting, but you might try a bit by tearing all the roots a-sunder and planting them separately, but this will require much more time and labour. We always find that the plants do best in rather firm soil; in light rich soil they grow rather too much to leaf.

SPIREA VERUSTA NOT FLOWERING (Idem).—Most likely it needs a little nourishment in the way of rotten dung, and a mulching all the winter. Most likely the plants suffered from dryness last summer.

NAMPS OF INSECTS (A Reader).—Your "great grandfather thrips" proves to be one of the small rove beetles, most probably *Oxytelus carinatus*, but it was smashed in the post. It keeps company with the thrips, most probably to devour it.—W.

EXHIBITING-STANDS FOR ROSES (G. W. H. Stourbridge).—Rose-stands should be 1 foot 6 inches broad, 6 inches high at the back, and 4 inches in front; length of box will vary according to the number of blooms. It is always a risk to move dormant buds. Success or failure will depend very much on the character of the winter.

LAMP-HEATING A PLANT-CASE (G. P. S.).—We will endeavour to tell you why the spirit lamp will not act in your little tank. First, the tank is too deep, half the depth would be better; your arch above the lamp should be depressed, so as to let more water rest there, and then the lamp should be lower. At present the flame of the lamp strikes merely against the top of your tank, and if the water is a little heated there, the heat will not descend to heat your 6 inches of cold water. You apply heat at top, when it ought to be communicated at the bottom; we can see that you will only have a chance by your present arrangement, by placing the flame a little lower than you now have the bottom of the lamp, depressing the semicircular top of the tank so as to have 2 inches of water there, and 3 inches elsewhere, and putting a cover round the lamp to prevent the heat escaping, whilst air for combustion is admitted. Without altering the depth of your tank you might also then do much by taking open tubes through the water, from your saddle-back roof, in middle. All our observation with such spirit lamps tends to show that they act most powerfully when the water is placed above them. For instance, with a hollowed-out tea kettle so as to have 2 inches of water between the concave inside and the rounded outside, and flow and return pipes of 1 inch in diameter, and a good spirit lamp beneath it, we believe we could heat several of these cases, the pipes either going in the sand or in a tank of 24 inches beneath the sand. Try what flattening the top of the saddle-back will do, and lowering the lamp and lessening the water; and if you do not succeed to your wish, boil some water elsewhere, reduce the depth of tank to 3 inches, and fill with hot water when necessary. You may succeed by this means, but you will never obtain heat enough by the present mode, because heated water will not easily descend into cold water. We have seen tanks 15 inches deep that were quite cool at the bottom, and yet very hot for a couple of inches at the top. If the case were ours we would not use water at all, but have openings to insert three or four Child's Night Lights, and other holes cut in one side of the tank to secure a circulation of hot air and sustain combustion. Nothing is gained by having water to heat by your lamp. We think that very likely your Camellia plant has had a check from want of watering.

PHILADELPHUS CORONARIUS (D.).—We have seen the *Philadelphus coronarius* in luxuriant health in all parts of the country, north, south, and midland.

DRIVING EVERLASTING-FLOWERS (Idem).—Everlasting-Flowers should be gathered before they are more than half blown, and dried in any place in the shade. We do not know what will prevent *Xeranthemum flower-stems* shrivelling a little, but the flowers are generally supported with a stick or a wire inside a small handful of stems. Probably some friends may give a better account of the mode of drying these flowers. Some of our friends by means of these, a few grasses, and a few evergreens, contrive to make their rooms very gay in winter.

FLOWER-BEDS (Idem).—Your cross planting of the flower-beds will do especially as respects the first group, if your bed 3, of Golden Chain consists of strong plants. In the second group, we would make 7 Yellow Calceolarias instead of variegated Alyssum; you might use the Alyssum strong as a centre to 6; then for 8, a Geranium, as *Stella*, would do better than *Calceolaria* for an edging of *Cineraria maritima*.

ACACIA GRANDIS NOT FLOWERING (J. M.).—Your plant has evidently grown very fast—too fast to come into a blooming state. Keep it another year in the same pot, and in other respects treat it as you have done this year; and when its pot is well filled with roots and the growth less luxuriant, it will doubtless flower. The cuttings having been removed from their source of luxuriant growth have, in consequence, been thrown into a blooming condition, and when your parent plant becomes less luxuriant it will bloom. We know of no other reason why it has not bloomed, while the cuttings from it have.

HEATING AN OUTSIDE PLANT CASE (A Regular Subscriber).—It is a great drawback being unable to cover the case. If the case were inside there would be no difficulty. Could a spiral tube from a gas-burner be taken through it? Perhaps the simplest plan would be to put two or three common bottles in it, when wanted, filled with water at about 160° or 180°. A gallon bottle of strong ale then were ought to keep such a place comfortable for the night. We would not use the water boiling in case it should break the bottle. A second might be used on a very cold night. We have described how a close vessel like a drawer might go under such a case and be supplied as needed with hot water. But we presume you could not get at it easily, and so a very severe night it might be frozen. Bottles of hot water will be the simplest mode.

SEA SAND (Omega).—This is no substitute for silver sand; white river, or even pit sand being better than it. Any Dublin nurseryman would supply you with any quantity of silver sand.

FEARS FOR WALL (Idem).—Jargonelle, Beurré Superfin, Beurré Bosc, Marie Louise, Ilacón's Incomparable, and Bon Chrétien. The Fears you allude to are early and late autumn Fears.

HEATING VINERY (Idem).—A fire will heat a house 30 feet by 12, but you must not expect to force early. We do not know where Mr. Rendle's treatise can be had. Apply to a bookseller.

VARIOUS (W. W.).—If you will send five postage stamps with your address you can have "Fruit Gardening for the Many" free by post. It contains full directions for all the pruning you mention. Fruit trees do not require such a supply of liquid manure as you seem to allow them. It makes them over-luxuriant. We cannot give an opinion about your Pear tree, as we do not know its state of growth. Fermenting dung or leaves are put over Sea-kale pots to force the plants; but there must be an abundance of the fermenting material. If this is done during the first week of November you may cut by Christmas. Neither ashes nor sand are needed inside Sea-kale pots. If you do not force, a little long litter over them will be desirable.

NAMES OF FRUIT (Woodford).—1, Hollandbury; 2, Emperor Alexander; 3, Parry's Earnain; 4, Marmalade Pippin; 5, Beurré de Rance; 6, Beurré Lefèvre; 7, Autumn Colmar; 8, Winter Nellis. (E. S.).—Your Pear is certainly delicious, but you do not say the name you have it under. It appears to us like Doyenné d'États; but that variety ought not to rot at the core as this does, and which is a great defect.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (*U. K. M.*).—1, *Athyrium Filix-femina*, var., perhaps laxum or pyramidal, but not in condition; 2, 4, *Lastrea dilatata*, var.; 3, *Lastrea semula*; 5, *Scolopendrium vulgare*.

POULTRY, BEE, and HOUSEHOLD, CHRONICLE.

PENS AT BIRMINGHAM POULTRY SHOW.

I SHOULD esteem it a great favour if yourself or any of your readers could state on authority, whether it is the intention of the Managers of the forthcoming Exhibition of poultry at Birmingham to enlarge the pens devoted to the principal varieties of fowls that will then enter into competition. Even to the most casual observer it must have been evident at first sight that the show-pens lately appointed at Birmingham for the reception of Cochins, Dorkings, Brahmas, Malays—in short, for every variety of the large breeds of fowls, have been decidedly too cramped in their dimensions, and without doubt a source of irrecoverable injury to the unfortunate birds, that for six or seven days and nights have barely room even to alter their respective positions without difficulty and great inconvenience to each other.

It is currently reported among poultry-fanciers that the Committee are resolved to confine the poultry exclusively to the "poultry bay," regardless of the amount of entries that may be obtained for next show within a few days of the time I am now writing. Until very recently such was not the regulation pursued—as Turkeys, Geese, Ducks, and some other classes enjoyed ample space in close contiguity to their (at that time) well-provided for neighbours. It is admitted that the pens were actually taken so much smaller than they were originally designed, to give greater space for the display of agricultural implements, and, I am sorry to add with perfect truth, to the exhibition and sale of a variety of shop goods also, not at all connected with agricultural pursuits. The policy of so doing is open to the gravest doubts. None but those personally interested can surely deny it was the poultry, and that alone, that has always been the object of most interest to the visitors at the Birmingham meetings, from the very commencement even to this day. To "see the poultry" and to meet friends has always brought together a number of lady visitors unparalleled in most of such meetings; and if this department of the Show is to be crippled and rendered less interesting simply to "make room" for the sale of goods, the legitimate position of which unquestionably is the shop of the salesman, it is not an idle conjecture to state that the very keystone to the success in future years of the Birmingham Show is thus worse than jeopardised.

It seems strange to pooh-pooh the poultry at Birmingham and literally thus show the cold shoulder to the Society's best supporters, but so it is; and in the hope that the remonstrances of others who exhibit large-sized varieties of fowls may be heard through the expressed opinions of such parties, and thus, conjoined with my own, bring about simply a return to the first-sized allotments given to the more weighty fowls at our mother Show, has caused these aptly-timed remarks from a very repeatedly exhibited—OLD COCHIN.

[We can endorse what our correspondent says relative to the too-limited size of the pens for the larger varieties of poultry. They are not only injurious to the birds, but diminish the pleasure of inspecting them.—Eds.]

SPARROWS AND POULTRY FOOD.—I think if your correspondent, who complains of the sparrows eating the poultry food, were to adopt the plan so often recommended in THE JOURNAL OF HORTICULTURE—that is, feeding by hand, and only giving the fowls just as much as they will eagerly clear up, there would be none left for the birds. To leave any lying about is wasteful; nor is such feeding so good for the health of the fowls. I have never suffered from birds myself, and always feed them in hard frosts or snowy weather on account of the good they do in summer.—B. P. ERENT.

WEIGHT OF POULTRY.

IN your remarks on the Crystal Palace Poultry Show in your last Number, you quote the weight of Mr. Fowler's Aylesbury Ducks, 22½ lbs.; and Sir St. G. Gore's Rouens, 18½ lbs. per pen.

Will you please say whether these weights are for one drake and two Ducks? I presume I am correct in this; but still my impression was, that first-prize birds would weigh more than the above. What do you consider a first-rate weight for drakes and Ducks of both breeds?

I have bred a good number of Rouens this year, and have this week weighed six drakes and twelve Ducks. The whole eighteen birds weighed 108 lbs.—an average of 6 lbs. for each bird. These were taken direct from our pond without any extra feeding of any kind; in fact, they are on the water night and day, and have only had the run of the farmyard with a large number of other poultry. What I wish to know is, whether you would consider such birds first-class as to weight, and what is the usual heaviest weight of both breeds at our principal exhibitions?

I may add, that last season I bred one lot of Aylesburies (nine in the brood), which weighed just 45 lbs. for the nine birds when fifty-eight days old. One drake weighed 5½ lbs., and another 5½ lbs.—RYBURN.

[You are correct. Each pen at the Crystal Palace consisted of a drake and two Ducks. The weights are also correct. We call 6 lbs. a capital weight for a Rouen drake, and 5½ lbs. for a Duck. Aylesburies should weigh 1 lb. more per head than Rouens. We once had the Aylesburies at Birmingham 8½ lbs. each, and we once saw a Rouen drake belonging to Mr. H. Worrall, of Liverpool, weighing 10 lbs. The weight you mention is unusual at such an early age. Aylesburies weigh from fat, Rouens from frame; and when we speak of capital weights, we do not speak of the first-prize birds of great competitors, but those that are good creditable inhabitants of a yard where their growth is not checked by want of food.]

SALE OF POULTRY AT EXHIBITIONS.

IN your last Number you state with reference to the Crystal Palace Poultry Show, that average birds at a moderate price are sure to meet with a sale. I am afraid my experience goes quite the other way, and I am much more disposed to look upon keeping poultry for exhibition as a very expensive and unsatisfactory amusement. From what I have read in your columns from time to time, I should have been led to a different conclusion had not my own experience contradicted it; and I am inclined to think, that while poultry-exhibiting and breeding is a very profitable business for a few well-known names, and does very well for others who can afford to buy stock regardless of price, for the general run of smaller exhibitors it is not only unremunerative, but absolutely entails a loss. I shall be glad if any of your readers can prove that I am wrong, or teach me how to set about the business in a profitable way, for I certainly have not found it hitherto. I sent some birds to the late Crystal Palace Show, certainly of average merit, and moderate price compared with the general run of prices there. They were returned unsold. I have had birds at other shows that took prizes and commendations, and only on one occasion effected a sale. This is not encouraging, to say the least, as the cost of sending birds to a show cannot be estimated at much less than 9s. a-pen.

I am always at a loss how to dispose of my surplus stock. I have now several good cockerels which I am anxious to part with. I cannot find buyers in my own neighbourhood, and they are too good to kill. If I send them up to Mr. Stevens for sale the chances are that they would not realise enough to make it worth the expense. What am I to do? If I want birds myself, I must give a good price for them, but when I come to sell my own, it is quite a different thing. In fact, it is all outgoing and no incoming. I think it would not be a bad plan if you were to set apart a column of your paper, in which your subscribers could for a small fee insert their wants, whether in the way of buying, selling, or exchanging, without the formality of an advertisement.

Perhaps you may have had similar complaints before, but

I am sure that the facts which I have mentioned must deter many from exhibiting poultry at all, and induce others who have entered on the pursuit with enthusiasm to give it up in disgust.—AN EXHIBITOR IN A SMALL WAY.

[The amount of money given for pens will at once prove that there is a good sale for birds at shows. It is known beforehand that at Bingley Hall from £700 to £800 will be laid out in the purchase of birds that are sent for sale. Many prices are prohibitory, but before two o'clock on Monday hardly a pen of average merit in the useful classes is for sale, if the price be moderate yet remunerative. Fancy and feather birds are subject to other rules, and are not of certain sale. Are you sure that your birds are of average merit?]

COLLINGHAM POULTRY SHOW.

THE eighth exhibition of this Show was held on Oct. 27th. The number of entries was in advance of those of last year. Many classes of poultry were especially good. The *Game* and *Game Bantams* were of first-rate excellence. The single *Game Bantam* cock of Miss E. Crawford was one of the most perfect little fowls exhibited for a long time. *Silver-spangled Hamburgs* were also a very superior class. *Cochins*, though not numerous, were very good.

The *Pigeons*, as is always the case at this Show, were of extraordinary excellence. Mr. Taylor's *Blue Pouters* were remarkable for length of limb and feather. In *Short-faced Tumblers* Mr. Oates took three prizes with his well-known pens that have won at Birmingham and elsewhere. The *Owls* constituted one of the finest classes ever seen. The *petite African* variety was shown in all colours—White (of which there were three exquisite pairs), Black, Blue, and White (with black and blue tails). So good a collection was never before exhibited. The *Trumpeters* were very superior, Whites taking all the prizes. *Turbits* were good, but many exhibitors seemed to have bred them with Owl heads, losing altogether the proper distinctive frog-like character of the *Turbit's* skull. The *Variety* class was well represented, first prizes going to the *Black-tailed Owls* before mentioned, and an extra fifth prize being awarded owing to the goodness of the class.

FRANKISH.—First, E. Brown, Sheffield. Second, T. T. Scaup, South Collingham. Third, T. Whitaker, Melton Mowbray. Highly Commended, T. Rogers, Walsall; Birth and Bolter, Sheffield.

DUCKING (Any colour).—First, R. Swift, Southwell. Second and Third, W. Dobby.

COCHIN-CHINA (Cinnamon and Buff).—First, — Staley, Collingham. Second, C. T. Bishop, Lenton, Nottingham. Highly Commended, C. T. Bishop.

COCHIN-CHINA (Any colour).—First, D. Causser, Erdington, Birmingham. Second, Mr. Staley.

GAME (Black-breasted and other Reds).—First, M. Billing, jun., Birmingham. Second, W. H. Swann, Farnfield. Third, R. Swift. Highly Commended, W. Boyes, Leverley. Commended, J. Doncaster, Flykeham, Lincoln; R. Swift.

GAME (Duckwings and other Greys and Blues).—First, J. Doncaster, Lincoln. Second, T. Carless, Notts. Third, J. Bradwell, Southwell.

GAME (White and Fife, or Any other variety).—First and Third, Miss E. Crawford, Farnfield. Second, C. Spencer, Thurlston.

HAMBURGERS (Golden-spangled).—First, Messrs. Birth and Bolter, Sheffield. Second, J. Dixon, Bradford. Highly Commended, W. Cannan, Bradford; H. Beldon, Bingley.

HAMBURGERS (Silver-spangled).—First, W. Cannan. Second, J. Dixon. Highly Commended, T. Rodgers; J. Key, Farnfield; H. Beldon, Bingley.

HAMBURGERS (Golden-pencilled).—First, W. Cannan. Second, Messrs. Wrigley and Fielding, Manchester. Highly Commended, W. Cannan; J. R. Jessop, Hull; J. Dixon.

HAMBURGERS (Silver-pencilled).—First, H. Beldon. Second, Messrs. Birth and Bolter. Highly Commended, W. Cannan; J. Dixon; W. Wood, Sheffield.

BANTAMS (Gold and Silver-laced).—First, T. H. D. Bayly, Biggleswade. Second, J. Staley (Gold). Highly Commended, R. Swift.

BANTAMS (Game).—First, Miss E. Crawford. Second, R. Hawksley, Southwell. Highly Commended, G. Maples; Miss E. Crawford; R. Hawksley; J. Newton, Chesterfield.

BANTAMS (Black, White, or Any other variety).—First, J. P. Gardner, Rogeley. Second, Rev. S. R. Hole. Highly Commended, T. H. D. Bayly; J. C. Brierley (Japanese Bantams).

DUCKS (Aylesbury).—First, J. Smith, Grantham. Second, R. M. Stark. Commended, J. Smith.

DUCKS (Houen).—First, Miss E. Crawford. Second, R. M. Stark. Highly Commended, H. Beldon.

DUCKS (Any other variety).—First, T. H. D. Bayly. Second, J. Dixon. Highly Commended, J. T. Fountain (Muscovy).

BARBDOOR FOWLS.—First, Mrs. Cooper, Collingham. Second, W. Wright, Collingham. Third, Miss L. Mantle.

GAME BANTAMS.—First, Miss E. Crawford. Second, T. H. D. Bayly. Highly Commended, R. Hawksley; E. Brown; C. Anklard, Chesterfield.

PIGEONS—Carriers.—First, E. Brown. Second, W. Boyes. Highly Commended, W. Massey; H. Yardley, Birmingham. *Pouters*.—First, W. Taylor. Second, E. Brown. Highly Commended, W. Taylor, Sheffield;

H. Simpson, Newark. *Almond Tumblers*.—First, H. Yardley. Second, H. Beldon. *Short-faced Mottles*.—First, W. H. C. Oates, Besthorpe. Second, G. H. Sanday, Nottingham. Highly Commended, G. H. Sanday; J. W. Edge, Birmingham. *Balds or Beards*.—First, W. H. C. Oates. Second, J. W. Edge. *Short-faced Tumblers*.—First, Mrs. Oates. Second, H. Beldon. *Barbs*.—First, H. Yardley. Second, G. H. Sanday. Commended, W. Massey. *Jacobins*.—First, T. Ellington. Second, E. Brown. *Owls*.—First, G. H. Sanday. Second, W. H. C. Oates. Highly Commended, H. Yardley; H. Beldon. Commended, W. H. C. Oates. *Trumpeters*.—First, Second, and Highly Commended, W. H. C. Oates. *Turbits*.—First, J. W. Edge. Second, J. R. Jessop. Commended, H. Yardley. *Fantails*.—First, G. H. Sanday. Second, J. Ellington. *Nuns*.—First, H. Yardley. Second, F. Else. *Any other variety*.—First, G. H. Sanday (Black-tailed Owls). Second, H. Yardley (Priests). Third, J. Percival (Archangels). Fourth, J. W. Edge (Swallows). Fifth, H. Yardley (Satinettes).

SECRETARY'S PRIZE.—*Turbits*.—Prize, H. Yardley.

The Judges were Messrs. Tegetmeier and Challoner.

JUDGES SHOULD BE ALONE.

My attention has been called to a paragraph which appears in your October Journal, headed "Judges Should be Alone," which I cannot allow to pass unnoticed, as it reflects discredit on me as Judge of the Poultry Show held at Crewe on the 30th September last.

"A LOVER OF FAIR PLAY," as he signs himself, would have had a better claim to such a title, had he in the first place written to me on the subject of his remarks, instead of giving such false information to the public through the medium of your valuable Journal.

Had "A LOVER OF FAIR PLAY" spoken the truth, I should have let the matter have passed, but as to his statement—viz., that whilst the Judge was making the awards an exhibitor entered the tent, catalogue in hand, and went round the pens with the Judge, and that when the public were admitted, that exhibitor met the owner of a prize and a certain conversation took place. I can only say that that statement by "A LOVER OF FAIR PLAY," is untrue from beginning to end.

I trust to your kindness in inserting this in your next publication; and as I am not afraid, like "A LOVER OF FAIR PLAY," to give my name, I beg to subscribe myself—JOHN HEATH, Judge of the Poultry Show held at Crewe.

POLLEN AND HONEY OF THE IVY—THE ADJUSTING-HIVE—FOUL BROOD.

REGULARLY in the early part of October when the ivy blooms, I have observed that an unwonted activity prevails throughout my apiary, the bees confining themselves not solely to pollen-gathering, but conveying also a considerable quantity of honey to their hives; at least 3 or 4 ozs. having been daily indicated by a hive suspended from a steel balance, and which has also afforded a very interesting register of work during the present season. This honey possesses in a great degree the strong flavour of the leaf and berry of the ivy, its presence in the hive being exceedingly disagreeable, and communicating its peculiar smell to much of the previously stored unsealed honey. It possesses little more consistency than water, and will splash from unsealed combs, leaving an odour on the hands difficult to remove. The ivy largely abounds in the immediate vicinity of my apiary, and during the autumn of last year this honey was collected in unusual quantities, much more so than during the present season. Pollen also is gathered to a large amount from the same sources, the bees returning to their hives not only dusted with it, but with long, irregular, stringy filaments of the whitish pollen adhering to their legs, very little being kneaded into regular balls. Cannot the activity observed in the apiary of your correspondent, Mr. Fairbrother, and the return of his bees dusted with dirty white powder, be attributed to the vicinity of ivy now in bloom? the high-flavoured transparent fluid which he found in their honey-bags also being of a very similar nature to the honey of the ivy.

I have this season had a further opportunity of testing the "adjusting" principle of working hives, which I first carried out satisfactorily in 1851, upon which occasion I removed a box-super of upwards of 68 lbs. nett weight of pure honey, and in the present season the superb glass supers, the weight of which were lately communicated to the Journal by my relative, Mr. S. B. Fox, in his article on "Bee-keeping in Devon," these glass supers being in all probability the

finest upon record. As an account of the "adjusting" hive has already appeared in *THE JOURNAL OF HORTICULTURE*, I need not again allude to the principle of its working, unless it should be desirable to bring it more prominently forward in a future communication. I believe it to be the best mode of obtaining large quantities of pure honey, but at the same time requiring that constant attention which none but the scientific apiarian would devote to it.

A very marked instance of "foul brood" has occurred in my apiary, the mischief existing unsuspected in the hive throughout the autumn and winter of last year, and it is only within the last two or three weeks that the true state of the case has been ascertained. The hive is a Ligurian stock possessing a dark but pure Ligurian queen, obtained from Mr. Woodbury last spring. She appeared to be a most fertile queen, having filled all eight combs throughout the box with brood in a very short space of time. From this period, however, a visible decrease rather than increase in the number of bees took place, the hive struggling on in a most unsatisfactory state up to the present time. No sooner had the "foul brood" controversy arisen, when, thanks to our friend Mr. Woodbury, the subject was brought so prominently forward, I saw the necessity of a thorough examination of the hive, and then discovered the nature and extent of the mischief, each comb being one mass of foul brood. The combs have been buried, the box burnt, and the few remaining bees now occupy a new and wholesome hive, and I anxiously await the issue, hoping they may recover lost ground and again prosper when another genial spring comes round.—*GEO. FOX, Kingsbridge.*

DRONES IN OCTOBER.

MAY I ask what inference I am to draw from the presence of drones in a hive now? I have kept bees for some years, and this is the first time such a thing has occurred. Out of four hives—viz., two old stocks and two new stocks—only the bees of the two new stocks, swarms of the middle of May, attempted to fill glass supers. I suppose the reason of this is that the two old stocks were exhausted of their numerical strength by a swarm and two casts from each.—*INQUIRER.*

[When drones survive so late in the season the probability is that the stock is queenless, and, therefore, its remaining inhabitants had better be united to another. Stocks that have been weakened by swarming very rarely work supers.]

BEE-KEEPING IN SOUTH LANCASHIRE.

As I read in your *Journal* each week the exultations of bee-keepers on the splendid season we have had, I am almost ashamed to write to you in another tone. It is well, however, that the capabilities of different districts and the experience of different apiarians should be compared, and, therefore, I am induced to write and tell of our misfortunes in South Lancashire. First of all, I should say that we have special difficulties to encounter. In the district, at least from which I write, we have on all sides of us manufacturing towns, and even a few smoky chimneys in our own village, all which are not favourable to the growth of flowers. But the great hindrance of all is the dreadfully rainy climate.

I began the year with two stocks, one of English bees in one of Neighbour's improved cottage-hives, and the other of Ligurians in a wooden bar-hive. The former stock swarmed on the 26th of May quite unexpectedly. Unfortunately I was away, and no one knew how to manage them, and the swarm was lost. I was able to collect a few of the bees from the centre of a thick hedge when I returned late at night, but the queen was not with them, and they returned to the old hive. Of the rest I am afraid most were killed by being shaken on the cold and damp ground. My second swarm was hived easily, and apparently very nicely, but this returned next morning to the old stock. The Ligurian stock did not swarm at all.

Thus I was left with my two old stocks, both seemingly in good condition. The summer was on the whole favourable. We had a good deal of rain in June, but there was a very warm fortnight in July in which they did so well

that I thought I might venture to take some honey from the Ligurian-hive before sending it to the moors. I took only about 5 lbs. of comb, leaving the weight (exclusive of the hive) about 13 lbs. This would have been quite enough if we had had even one fine fortnight in the autumn, as there was a great deal of blossom on the heather. Unfortunately there was hardly one fine day. On bringing the hives back about a fortnight ago, I found each had lost about 3 lbs. For each of them, therefore, it was a case of feeding-up for the winter, but especially for the Ligurian-hive.

The English bees have taken their food very quickly and greedily, and are now quite safe; but the Ligurians decline the sugar and water I offer them, or only take it very slowly. Can you tell me what I am to do? I wish to keep the stock if I can, as I think I could not get another Ligurian-hive in this neighbourhood. I have been feeding them at the top with one of Neighbour's feeders. The opening in the hive is not wide enough for the neck of a bottle, or I would have tried bottle-feeding. I am now having something made in zinc with a neck narrow enough to insert, but as the frosts have begun I am afraid I am too late. Is there any way by which I may keep them alive till next spring? If you, or the great bee-master of Devonshire, or any other of your correspondents can advise me, you will much oblige—*A SOUTH LANCASHIRE BEE-KEEPER.*

P.S.—I may add that all my neighbours here seem to have been little more fortunate than myself, and, instead of taking any honey, have been obliged to feed-up their stocks liberally for the winter.

[Try the bottle for your Ligurians applied in this fashion, through a block of wood with a bit of perforated zinc

interposed. The neck of the bottle need not enter the hole in the top of the hive.

SOURCES OF POLLEN.

I ACKNOWLEDGE with thanks the kind and lucid reply of "A DEVONSHIRE BEE-KEEPER," to my suppositions and remarks in page 323. I am forced to believe where I cannot understand; but as I willingly do this, and press it upon others to act likewise in spiritual matters, I can the easier submit to do so myself with a good grace in earthly ones. The particulars mentioned from Maraldi, Debrau, and Co., were unknown to me. I think I once read some remarks of Huber, which led me to suggest the supposition I advanced. I do not regret my last letter, neither will any of your readers, since it has drawn forth so interesting, so instructive a reply as follows it; and still less reason for regret shall I have if my house and apiary are honoured in consequence with a visit from the head of our clan.

Bees have been working much lately on the ivy. The colour of the pollen is yellow. Some weeks ago mine appeared like dusty millers, and they were then working on some flowers in my garden, called, as I have been told, malope—I suspect of the mallow tribe.

I have for many years been puzzled to know whence a pollen is collected of the colour of the young larch cones when they first appear, and about the same time; yet I never

saw bees work on larch cones. It is not the rule either, that the colour of the flower is the colour of the pollen.

I never had my attention called to the fact that bees will not remove chilled brood till in the last Number. They certainly will remove dead bees in the pupa state, and lug them out fast enough too. They will destroy large pieces of comb if it does not suit them. I once saw a piece destroyed from the middle of the hive as large as the palm of my hand in a single afternoon, and the place was in due time filled up with new comb. I dare say more was renewed, but I can only speak to what I saw.—A HAMPSHIRE BEE-KEEPER.

AN EXPERIMENTAL APIARY.

Mr. Lowe's lengthy exposition of his views with regard to "an experimental apiary," which, he maintains, "can never be a thoroughly prosperous one," might very well have been spared. It is to be presumed that he means a purely experimental one, by which I understand an apiary established for the sole purpose of experiment. If so, what then? Who ever doubted, or could doubt, that the sort of experimental apiarian whom he attempts facetiously to describe, and hold up to scorn, would fail—fail, that is, to obtain honey, which, according to Mr. Lowe, is the sole end and object of bee-keeping?

No doubt, however, even the peculiar bee-keeper whom Mr. Lowe has in his eye, would defend his management by pure experiment, and maintain that his object was quite as legitimate and interesting as Mr. Lowe's, and possibly as useful to others in the long run. But, after all, where is the man in our small bee world who answers to Mr. Lowe's description? He has raised up a man of straw to provide himself with the exquisite pleasure of knocking him down. Let him enjoy his postprandial recreation. I for one have no sort of inclination to grudge him the felicity of his crow. If, however, Mr. Lowe is not speaking of a purely experimental apiary, then he has simply condescended to misrepresent and misunderstand from motives best known to himself the experiments prosecuted, and the objects aimed at in those experiments, by your esteemed correspondent, Mr. Woodbury. As to his "motives," Mr. Lowe himself lifts up the veil, and permits us to see them. The occasion of his sarcasm, the secret of his bitterness, hitherto unaccountable, is now revealed in one short sentence of his recent communication. "My tone and style," he says, "are already thought by some to be too severe; and it appears, though I must receive contradiction, I must not be given to philippic." This gentleman has "received contradiction," so at least he imagines, in regard to some matter of apianian research. Unable to brook opposition, even at the hands of so kindly an opponent as Mr. Woodbury, forthwith he dips his pen in gall, and we have the result in the "philippic" of caustic sarcasm and misrepresentation which appeared recently in your columns. Really this is too bad, and it is time that a strong protest should be advanced against a style and spirit so adverse to all friendly criticism. "*Ei centem dicere verum, quid vetat?*" But this sort of writing can only prevail at the cost of all profitable and harmonious co-operation for the advancement of our favourite pursuit. Till Mr. Lowe took up the cudgels, or rather (to use his own metaphor), commenced traversing the bee field with hob-nailed boots, regardless of his neighbour's corns, we were at peace. Let us hope that we shall now be suffered to return to peace.

In the meanwhile let me suggest to him to reflect upon the possibility that "others see as well as you." A notable instance will be found in this very question of foul brood. Very positively he asserts that "decayed and abortive brood in all stages are not removed by the bees." As positively I assert from my own experience that they are removed by bees. Not, of course, thoroughly in weak hives, in which, consequently, I fully agree with him, "they must remain a permanent evil," if not removed by the bee-master's hand. But in strong hives the bees are fully up to the requirements of the case, and remove all impurities as they occur.

With regard to artificial swarming as compared with natural swarming, Mr. Lowe has not fairly put the case. To the "lover of nature," the natural swarm is, no doubt,

one of the most delightful of rural sights and sounds, even should the said swarm speed away, *agone facto*, beyond the ken of the distressed owner. Even so to the artist's eye, the dilapidated cottage, discoloured with dirt and tenanted by a ragged peasantry, is more charming than the trim and cleanly dwelling of the thrifty artisan. But how many a disappointed bee-keeper would gladly, and does gladly, learn the art by which he may secure his swarms? and warmly will he thank the much-abused experimentalist who puts him in the way of scientifically managing his bees, especially at the swarming time.—E. & W.

OUR LETTER BOX.

DOERING COCK UNABLE TO STAND (G. D.).—All the symptoms and his slow recovery intimate that a small blood-vessel is ruptured in the head. The hot sun-bath and the inflammatory action incident to moulting were the probable causes.

WHITE FEATHERS IN WING OF A BUTT COCK (J. Carr).—The white feathers would constitute what is called a mealy wing. It is not a disqualification, nor is it a serious disadvantage. Nevertheless, it competition were very close a clear buff wing would be preferred to a mealy one.

COCHIN-CHINAS LOSING THE USE OF THEIR LEGS (G. C.).—The disease you mention is probably cramp, and is caused by the damp floor. If you have gravel in your neighbourhood cover the flooring of the house some inches deep with it. When the cramp is coming on give the fowls bread steeped in strong ale directly.

KEEPING BANTAMS AND SPANISH FOWLS TOGETHER (J. R.).—It is a disputed point. Our opinion is that they may be kept with impunity.

ROCKY POULTRY (S. B.).—You need not clear off all your poultry. If you did so, and intended to rest the place, it should be empty for months. Clear off the sickly birds such as are hopelessly ill. Limewhite all their roosting-places. Feed them well on bread and ale. Put some camphor in their water, and let all their roosting-places floors be covered with dry gravel some inches deep. We believe this will cure them. If you were determined to do away with them for a time you need not send away the Geese and Ducks: they are not subject to such disorders. We think if you had run about, the Turkeys would be sure to catch it—they have a weakness for it. If your Geese, Ducks, Turkeys, and fowls roost together you will not have them healthier. Fowls should roost by themselves. Turkeys the same. Ducks and Geese may consort, but turkeys must be separate.

COLOR-BED PLATES OF POULTRY (Country Poultry-Fancier).—The best are in "The Poultry Book" by Mr. G. W. Johnson and the Rev. W. W. Winfield. It was published a few years ago.

WEIGHT OF PIGEONS (J. F. L. K.).—From 4 lbs. to 4½ lbs. is considered a good weight for a pair of Pigeons. I am not aware that there is any standard weights for the other breeds. Carriers and Pouters are liked large; Tumblers, Turbitts, Owls, J. cobins, and Carriers are preferred as small as can be obtained. If wanted for the table, a cross between Dragoon and Pouter or Dragoon and Trumpeter will be found useful. But I expect most profit is made by breeding first-class birds of any of the principal varieties.

—E. F. BENT.

CHOICE A PIGEON LOFT (S. Vincent).—The furnishing of a loft for the accommodation of Pigeons may be effected in the following manner:—First see that the floor is sound and the door, skirting, &c., secure against rats. A window or opening should be made on the south or south-western side to admit air and light, and an area or trap made of lathwork or wire netting should be placed outside so that the Pigeons may go therein to sun themselves, and where they can also be provided with a bath. The internal fittings may vary according to the taste of the fancier or the shape of the loft. Separate pens provided with nests, and each being made to close, may be erected round the walls, of which Mr. Eaton has published a diagram, or, if the slanting roof comes down to the floor, the pens may stand back to back in a central row. Others place shelves against the walls 18 inches apart one above the other, and divide them by partitions at every yard, nailing boarding down the front so as to make a recess at each end of the three-foot divisions for the nests, or to receive the nest-pots, if such are used; or it may be supplied with boxes or any other form of nest, only bearing in mind that each pair of Pigeons require a pair of nests, and that each couple of nests must be separated or divided from the others, so as to form a private residence for the pair of Pigeons inhabiting them. Water is best supplied in a large earthen fountain. Food may be given in a hopper, or, if preferred, by hand; but in this case they require constant and regular feeding. Small beans, old tares, and lentils are perhaps the best food for Pigeons. S. Vincent will find more details in the "Pigeon-Book for the Many."—E. F. B.

FARROW PICKING OUT ITS FEATHERS (E. B.).—Let it have daily a bath of tepid water. This is best afforded in a soup plate. If the bird does not voluntarily bathe pour tepid water over it daily through the rose of a watering-pot, giving not a sprinkling but a good soaking.

LEAD PIPE (A Subscriber).—You can obtain sulphide of potassium of any practical chemist, but we do not know the cost. It cannot be dear, and a small quantity would suffice for a great length of pipe. We should use a hot solution nearly saturated.

LONDON MARKETS.—NOVEMBER 2.

POULTRY.

The supply is, if anything, rather less; but the dullness of trade prevents any rise in prices.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 49.5°, and its night temperature 34.6°. The greatest heat was 63°, on the 12th, 1841; and the lowest cold, 18°, on the 15th, 1848. The greatest fall of rain was 1.24 inch.

LIFTING THE ROOTS OF VINES, AND REMAKING THE BORDER.

LIFTING the roots of Vines and remaking the border is an operation in which several correspondents are interested at the present time, and as they appear to be entire strangers to the details which are necessary to insure success it has been resolved to devote a paper to the subject, more particularly because I feel certain that there are plenty who will agree with me when I say that there are hundreds of Vines in the country in an unsatisfactory and unfruitful condition from no other cause than that their roots are deep down in an adhesive, wet, and consequently cold and ungenial soil. It would be easy to enumerate a dozen cases within my own knowledge, and partly in my own practice, where the most marked benefit has resulted from lifting the roots of Vines,

and replanting them in better-constructed borders. True there are other ways in which the roots of Vines can be brought to the surface of the border, but if the soil is adhesive and not well drained, there is no other way that I am aware of by which the evil can be so efficiently remedied.

The first question which very naturally arises in the minds of our correspondents is as to the best season to lift Vines with the greatest possible chances of a crop of Grapes the following summer. To this I have no hesitation in replying that, waiving all contingent circumstances, the best time is early autumn, before the leaves and roots have ceased their active functions, and while there is still a high degree of natural warmth in the soil. The simple fact—would that it were thoroughly explained to every child—that the action of roots and leaves are reciprocal, and depend one upon the other, is sufficient reason, apart from experience, for concluding that autumn is the best time. So far as the operation of lifting is concerned, the great matters on which a crop the following season depends are, that there should be root-action to repair as much as possible, before the resting season, that shock unavoidably consequent on the breakage of roots in disentangling them from an adhesive soil; and that there should be time to regain, by a good hold of fresh soil, a position similar in kind, if not in extent, to that enjoyed by a Vine established in suitable soil. By delaying the operation till winter all chance of accomplishing this important object is lost. The roots must then lie a long time with all their wounds exposed to a cold soil,

and without having that natural hold of it peculiar to roots which have been active in it in autumn. Another disadvantage arising from winter-lifting is that in spring the growing Vine has exhausted its stored-up sap, and the mutilated roots do not come bounding into action, to carry on unchecked the progress of the Vine, with that energy and readiness as when the fresh rootlets have established themselves in autumn before the leaves of the Vine have ceased to act. True, this weak point may be assisted by placing warm beds of leaves on the border a little before the Vines start into growth, and by this means young roots may be formed much sooner than otherwise; but, in the case of Vines at least, this is not the order of nature, although it may be the best thing to do under such circumstances.

There can be no difficulty in deciding on autumn-lifting with the leaves on the Vines and the soil warm, in preference to delaying it till winter; but there are several considerations which, when autumn-lifting is not convenient or practicable, make me prefer deferring it till the spring just as the buds are swelling. Apart from the fact that there are less chances of suitable weather in winter than in spring for performing such work in a proper way, there are objections already named to the broken rootlets of Vines being allowed to lie all winter in a cold border from which those which ought to be of most service in spring are sure to suffer more or less. It would certainly be very questionable gardening to shake out and repot a Fuchsia at the dead of winter or immediately after it had shed its last leaf, and then to stand it in a cold shed or under the greenhouse-stage till spring. It would certainly be better to repot in autumn and subject it to such treatment as would insure fresh root-action before it shed its leaves, or to leave it till spring when it was just bursting into growth; and I know of nothing peculiar to the Vine which warrants the application of any other principle.

There are several causes which in some cases make it undesirable to disturb the roots of Vines in early autumn—such, for instance, as that of our correspondent, to whom a reply was given last month, who had his crop still on the Vines, and wished to let it hang through the winter. To lift the roots of such Vines would have been detrimental to the fruit, and, besides, with Grapes on Vines, such management as is most likely to insure success could not be carried out. It may also be inconvenient on account of other matters, such as lack of time and the necessary material. In such instances experience warrants me in advising the delay of the operation till spring, just as the Vines begin to swell their buds, and in the meantime to get ready the soil, and, if possible, to protect it from wet till it be required.

The precaution of protecting the old border from wet by wooden shutters, which has been taken by our correspondent "C. V.," is strongly to be recommended, in order as much as possible to preserve the roots made last season. It would be well at the same time to open a drain all round the front and end of the border sufficiently deep to prevent water from standing about the

roots; for success depends in no small degree on the careful preservation of as many of the young roots as possible, and in deep damp borders they are, alas! scarce enough.

I have ripened a crop of Grapes in the end of June where the Vines had been entirely lifted the previous autumn, and I have removed Vines after they had shed all their leaves from one viney to another in which forcing had just commenced, and cut a fair crop from them as early as May. And plenty of gardeners there are who have done the same, and who would also recommend the lifting of Vines to be done either early in autumn or to leave them till forcing or growth was about to commence. On the other hand, some have ruthlessly sawn the roots entirely, or nearly so, from their Vines, and matured a crop from them the same year; others have lifted them in June with Grapes ready to thin on them, and yet brought the crop to maturity. But except in special cases such high-skilled and daring strokes are not to be recommended. In fact, where the Vine roots have the run of borders, both inside and outside the vineries, the safest practice is to lift the inside roots one year, and those outside another. When this can be done there need be no fear, all other things being favourable, of obtaining Grapes in the following season. When speaking thus of a crop in the following season it must be borne in mind by the inexperienced that the foundation for a crop lies in the proper maturation or ripening of the wood in the previous year; and this is just what is so frequently wanting in Vines that require lifting, and what should be aimed at as much as possible the autumn in which they are to be lifted.

It has been remarked that there is another way of bringing or enticing Vine roots to the surface besides that of lifting the roots and entirely removing the border; and which is more commendable under certain circumstances than partially or entirely lifting the roots—in the case, for instance, of borders which lie comparatively dry on a subsoil of gravel or sand, to which no great objections can be urged, and when the roots have got down and established themselves in the bottom part of the border, leaving a mass of inert soil on the surface without a single root. This is a very common occurrence, and in the successful cultivation of the Vine it is considered of great moment that this state should be just reversed, and that a mass of active roots should be brought to the surface and encouraged to establish themselves there. Those who have only one viney, with all the roots in an outside border, and who, consequently, cannot lift one half the roots one year and the other half the next, and who at the same time do not care to incur the least risk of losing a year's crop by carrying out the radical means recommended for Vines that have their roots in thoroughly wet soil, can do much towards accomplishing the end in view by removing all the soil from the surface of the border down to the roots. Then dig out a drain 18 inches wide and sufficiently deep to be below the principal roots and made-border, and fill it up with what is called a "rumbling drain" of brickbats or stones. If a tile drain be placed at the bottom all the better—not, however, on the top of the stones, as one of our tenants here told me he found, to his great amusement, an Essex notable doing in what he called imitation of the Scotch system of draining. Then cover the roots with a six-inch dressing of well-pulverised lime *débris*, thoroughly-rotted manure, and turfy loam in equal proportions, and well mixed together in a dry state. Just as the Vines are to be started, a bed of leaves, sufficient to generate heat enough to warm at least the six inches of top-dressing, should be placed on the border, and over all something, such as a thatching of well-dried straw, to throw off rains: the whole to remain till midsummer. The stone drain in front cuts off all surrounding water, and in itself that is no small benefit to a Vine-border where the roots are deep and wet. When the border is uncovered it will soon be discovered that the open rich soil on the top, with its temperature raised above the lower strata of the border, is sufficient to entice upwards a lot of roots of a different order to those found at the bottoms of borders. In midsummer I have sometimes found young roots up to the top-dressing into the leaves themselves. Now, let the same process of adding a few inches of top-dressing and the bed of leaves be repeated, and after the lapse of two or three years it will be seen that the surface of the border has the lion's share of

active well-ripened roots, and that the Vines will be correspondingly improved.

Not having time at present to detail the process of lifting the roots and forming new borders, &c., I will conclude by advising our correspondents to delay the process now till spring, and in the meantime to keep their borders as dry as possible, and next week I will return to the subject.

D. THOMSON.

THE PAMPAS GRASS—TURKEY MILL GARDENS.

SINCE the remarkable winter of 1860-61, which killed so many fine plants of the Pampas Grass in various parts of the country, we have not heard so much of it as before; and though now and then reports are made of some favoured plant flowering with an extraordinary number of spikes, the cultivation of the plant in stations suited to its flowering has been much circumscribed. In fact, so much so, that it is a question at the present time if there be as many plants in cultivation as there were three years ago, the more especially since its flowering in cold and late situations is a hopeless affair, excepting in very dry and hot seasons, which only occur once or twice in a dozen years or so. However, when a fine plant does flower, it is a noble object. No other herbaceous plant that I am acquainted with can equal it, and flowering, too, at a time when the gaiety of summer-flowering plants is on the wane, it is highly acceptable.

The present season has not passed over without affording a due proportion of blooms on this highly graceful plant. I noticed some very good blooms on plants in a nursery at Bagshot, about the middle of October, the soil being of that black peaty kind so favourable to the growth of the Rhododendron, and such-like shrubs. Amongst a number of plants all flowering at the time, three or four forms of growth or characters of flower might be made out amongst them, and all beautiful. Some of the plants evidently had a great many spikes of bloom on them, and the foliage exhibited a more than usual tint of bright green. Some other places I have seen this autumn also possess fine examples of this highly ornamental Grass; but by far the noblest plant of the kind I have seen in bloom is in the garden of the Messrs. Hollingworth, of Turkey Mill, near Maidstone, where a plant had 130 spikes of bloom on it, being, in fact, literally covered with it. The numerous stems supporting the fine feather-looking plumes rose in regular order, so as to form a most symmetrical head, which the most expert plant-dresser for a flower show could not have improved, even in his own idea of forming a sort of balloon-shaped plant. The dense forest of flower-spikes rising so regularly on all sides, as well as in the centre of the plant, left nothing to be wished for on the score of symmetry, and certainly still less on that of profuseness, for the whole of the upper surface was covered with graceful feathery plumes. The situation of this fine plant was on the sloping banks of a piece of ornamental water, and about a dozen yards or so from it; but I do not think the spot was at all a moist one, but the plant might benefit by the vapour from the water. Some other plants growing closer to the edge, and with their drooping foliage lapping in the water, were equally healthy, although none of them possessed so attractive a head of bloom as the specimen previously described; but they seemed younger plants, and in due time I have no doubt but that they will be equally profuse in blooming.

Besides the plants of Pampas Grass just described, the grounds contained some excellent specimens of Conifers. A *Wellingtonia gigantea*, some 14 or 15 feet high, was a perfect model. Some specimens of *Thujaopsis dolabrata*, *gigantea*, and *Lobbi*, were also good and promising, and that really distinct but somehow neglected *Cupressus*, *C. Udeana*, with its silvery foliage, promised to become a fine specimen. This *Cupressus* is not so much planted as it ought to be, considering how widely it differs from the kinds often met with. *C. Lambertiana*, and *C. macrocarpa* were, I believe, also both well represented at this place, as well as some other favourite shrubs and trees. But the principal feature of the place to the frequenter of flower shows was the extensive collection of Roses, numbering upwards of five hundred varieties, I was told, which were here grown in excellent condition, as the fact of Mr. Hollingworth and his gardener,

Mr. Holder, winning so many prizes at the metropolitan and other shows in the past and previous seasons has testified. The situations in which the Roses were planted were varied considerably, the nature of the ground affording facilities for this being carried out.

The garden or dressed ground may be roughly described as an irregular plot surrounding a piece of ornamental water of some two acres or more in extent, the bank in some places gently shelving to the water's edge, in others rising abruptly in masses of natural rock (Kentish rag); and it presented many natural features of interest, which had been duly taken advantage of, as affording sites for climbers, Ferns, shrubs, and trees of various kinds; and ever and anon Roses were found in all available places. It is not, however, my purpose here to describe the management of these, as the fact of so many prizes finding their way into the hands of the spirited owner shows that they are well grown. No doubt, the good natural soil of the place is conducive to success, and the proximity of water may, perhaps, be advantageous also, for certainly the latter has much to do with a good stand of Dahlias during a dry period in summer, and these flowers are also grown here to great perfection. The whole place presents many features of interest, reflecting great credit on the spirited occupiers and their intelligent gardener.

I cannot close this notice of the Pampas Grass without mentioning a singular fact connected with a plant we have at Linton Park. This specimen was planted out, I believe, in 1855, and flowered pretty well in 1857, and I am not certain if it did not do so in 1856. It also flowered well in 1858 and 1859. I have forgotten whether there were any blossoms on it in 1860 or not, but there were a few in 1861, which was a rather barren year in flowers of this kind, so many plants being irrecoverably injured; but the autumn of 1861 being favourable and the plant healthy, I made sure of an extraordinary bloom in the following season, when to my surprise there was none, and none this year either. I confess being at a loss how to account for this, for the plant has every appearance of health and vigour and has grown to a large size. The site is a rather moist one for this place, and the plant remaining unmoved for so many years would certainly favour the production of flowering-spikes rather than otherwise, but such is not the case. From its not having flowered last year I expected a greater profusion of bloom this season, but this not being the case, I am at a loss to account for the circumstance.

We have other and younger plants flowering very well, one not many yards from that here alluded to, but on drier ground; but generally the best flowering plants I have seen have been growing in rather damp places, or at all events near to water. An open space is, I believe, better suited to them than a place surrounded by shrubs, and certainly they look best when seen on all sides, the graceful drooping blades contrast so well with all around them, and differ so widely from all other or ordinary forms of vegetable life. The plant is much admired even when not in flower, but when it is surmounted with its feathery plumes, presenting various tints of white, drab, grey, and purple, the picture is complete. Sometimes the character of the adjoining scenery adds to the effect. A plant we have here with a tolerably good head of bloom on it, has for its background a mass of foliage of the Sumach, the handsome pinnated leaves of which, flanked as they are by ordinary evergreens, afford a very interesting variety.

Certainly the Pampas Grass as an ornament to lawns ought to be more extensively grown than it often is, and, perhaps, a still better site may be found for it in some of the open spaces beyond the bounds of the close-shaved turf, where the dressed ground gradually merges into the natural. In such a place, and in a suitable situation, the Pampas Grass is not one of those miffy tender things requiring to be looked at every week; but after it has had a fair start it is capable of taking care of itself, and though it would not be fair to allow it to suffer from shrub or tree, I do not think it would fail to contend successfully against all ordinary herbage, however wild and rank.

J. ROBSON.

ANDROSACE LANUGINOSA OF WALLICH.—It is odd to see such prominence given to this by a contemporary as a new

and rare plant, when it is to be found in every botanic garden and in the London nurseries. It is a very pretty plant, and does very well planted out in summer.—PRIMULA.

INSURANCE OF GLASS FROM HAILSTORMS.

As it is not, perhaps, generally or sufficiently known that glass can be insured from the damage done by hailstorms, I am tempted to tell your readers how it may be effected, premising that I have no shares in any insurance office. The only office that offers to insure glass houses is the Royal Farmers' Insurance Company, Strand, London, and they require the following rules to be adhered to:—

Each house to be numbered, and the kind of glass used in building it to be described in the proposal as follows:—

On house No. 1—1000 square feet of British sheet glass at 3d. per foot.

On house No. 2—1500 ditto ditto at 4d. per foot.

On house No. 5—1200 ditto ditto at 5d. per foot, and so on.

The glass should be valued according to its quality, but allowing at least a halfpenny per foot over its value to cover the charge of reglazing: thus glass costing 2½d. per foot should be insured at 3d. per foot. Mr. Rivers, of Sawbridge-worth insures the greater portion of his glass, 33,000 feet, at 3d. per foot, including 21 ozs., 16 ozs., and crown glass, for which he pays an annual premium of £4 4s. 9d., not quite 3s. per 1000 feet. This seems not too high a price for a little peace of mind during every summer, when a black cloud and a clap of thunder makes the owner of glass houses quake for fear of hailstones.—CONSTANT READER.

HOW TO CULTIVATE VINES IN POTS.

This branch of horticulture has been frequently written upon, and these notes are not jotted down with the view of imparting instruction to my older brethren, but to afford encouragement to those who with limited means wish to be successful in this most interesting mode of fruit-culture.

It is now a little more than three years since my present employer put up several vineries and an orchard-house (the orchard-house and its tenants must form the subject of future notes), and when the houses were finished, and the hot-water apparatus completed, he very naturally wished to obtain an early produce from his outlay. He therefore purchased a number of pot Vines, of varieties recommended by nurserymen as having special qualities for pot-culture, to supply fruit until those planted in the borders attained a fruiting condition.

What their treatment was the first year I do not know, as I only took charge of the Vines two years ago. This I know, that these bought Vines produced no fruit the first year, and when I first saw them they were in a most deplorable condition, with the wood unripe, and the buds imperfectly formed. They had, during the month of October, received a surface-dressing of good turfy soil, mixed with a tolerable amount of rotten dung and bone dust. I pruned them in due course, and about the middle of January they were started into growth. As soon as the buds began to break they were supplied with weak liquid manure two or three times per week, and as the shoots developed themselves the liquid manure was increased in strength, and applied more frequently. Most of the bought Vines yielded tolerable crops—more than could be well expected, considering the state of the wood, for they produced from four to seven bunches each.

Now, in addition to these bought Vines, were a large number which had been raised from eyes the previous spring, the eyes taken, without being named, no doubt, from the Vines permanently planted in the borders, and cut down in the usual way. Most of these Vines had been grown in rather small pots, and, as a matter of course, their growth was small in proportion. These, with the exception of one or two of the strongest, were cut down to two eyes, and along with the others were started into growth. They broke well, the best shoots only being encouraged, and during their early growth were assisted by frequent applications of manure water. Some of the strongest were shifted into their fruiting-pots in the early part of the summer, and the others remained until autumn. They each soon reached the top of the respective houses in which they were growing,

and made canes something resembling a gentleman's slender walking-stick.

During the autumn the remaining Vines were moved into pots of about 12 inches in diameter, and 12 inches deep. This size I consider quite adequate for all ordinary purposes, and Vines grown in 12-inch pots with ordinary care may be expected to produce from 5 lbs. to 8 lbs. of fruit each. The compost in which they were potted consisted of two-thirds good hazel loam chopped up and left in lumps about the size of an egg, with some rotten dung and pounded bones to form the other part. The pots were well drained with broken crocks, and over the crocks was placed a layer of boiled bones about the size of a walnut. The soil was well tamped into the pots, and a sufficient space left to hold water. They were pruned to 6 or 7 feet in length, according to their strength, and being placed in the position they had to occupy, about Christmas the early house was again started.

I prefer bending down the Vines to a horizontal or recumbent position until they begin growing; this causes an equal circulation of sap, and makes the buds break more regularly. By this means I succeeded in breaking every eye in the pot Vines, with the exception of one or two nearest the pot, and almost every branch showed fruit—some shoots two, three, four, and even five bunches each. The usual routine of disbudding, stopping the laterals as they advanced, thinning the bunches, also the thinning of the berries, and the syringing, were duly attended to.

One very important point requiring special attention is the watering. This must be varied to insure success. Plants, like human beings, prefer a change of diet. I obtain my supplies of liquid manure from a well which receives the drainage from adjacent stables. This, when weak through heavy falls of rain, I strengthen with guano at the rate of about two ounces to the gallon. I also employ the soap-suds from the laundry, mixed with cowdung and guano as a change.

Those Vines started in the earliest house ripened a few bunches in the early part of May, while those started in the orchard-house, and brought into the lateinery as accommodation could be found them, are still in fruit, and may be up to Christmas. Thus with pot Vines alone, independent of what has been taken from the rafters, we may have a supply from May till December.

Now, let us look at the produce of these pot Vines. Lady Downes' appears to be a shy bearer in a pot; at least with us, the produce was but small, and it was the only one that could be considered a failure. It was not forced much, being only started in a late house towards the end of February. Trentham Black appears to be not very free in a pot, but the fruit was large and exquisite. Perhaps some of your readers may have succeeded better with it in a pot. Muscat St. Laurent and Chasselas Rose Royale I consider useless; the latter produced eight or nine bunches to a pot, but the berries were small, and the flavour different. Chasselas Musqué may be considered good for pot-culture, and also for forcing, as it is a free bearer and an early variety. Black Frontignans produced from nine to eleven bunches on a Vine; White Frontignans, from ten to seventeen bunches; and Grizzly Frontignans carried seventeen bunches; and one Grizzly showed upwards of thirty bunches on a rod about 6 feet long. Many of the bunches were as good as may be ordinarily seen on rafters. Black Hamburgs produced three, four, and up to fourteen bunches. One Black Hamburg I only allowed to carry four bunches, and weighed the produce. The first bunch weighed 2½ lbs., the second and third were 1½ lb. each, and the fourth 1 lb. Thus one Vine with only four bunches produced 6½ lbs. of fruit fit for any table. I should like to know what variety of Hamburg the latter is. The bunch is large and heavily shouldered, and tapering at the point; the skin deep black purple; berries roundish, and of good flavour; and the foliage when changing colour assumes a beautiful pink tinge very different from any other variety I know. [Probably Black Champion.—Eds. J. or H.]

I am certain any one possessing only a small pit, with artificial heat at command, may succeed in growing fine Grapes from pot Vines. The minutiae of propagation and the after-management of pot Vines have been so frequently detailed by Mr. Fish, that I might refrain from saying anything on the subject. But, as we seem almost in the height

of a Grape-growing mania, and having given the cultivation of Vines in pots special attention, I may be excused in saying a little for the benefit of beginners.

The plants are, without doubt, the best raised from single eyes obtained from strong, healthy Vines, and should be procured as early after Christmas as possible. There are many different ways of making the cuttings; perhaps as simple as any is to make them about 1½ inch in length, and to place them horizontally with the bud uppermost in small 60-sized pots, filled with light, rich soil, and well drained. These pots should, if possible, be placed in a bottom heat of from 70° to 75°. As soon as the small pots are filled with roots they must be transplanted into larger pots—say large 48's. The compost used for this shift, and for every successive potting, should consist of two parts turfy loam, and one part very rotten dung; to this add, if the loam is inclined to be stiff, a little sharp river sand. A good sprinkling of sifted bones, with a little charcoal and a little lime rubbish, will do no harm. Let these be well mixed and incorporated together. The soil should be well warmed in a stove before using it, or the plants will sustain a serious check, and when water is applied it must be in a tepid state. They will soon require another shift, which should be into eight-inch pots, and finally into 12-inch pots. Some people recommend larger pots, but then they are much more inconvenient to move about.

I invariably allow the canes to become about 8 feet long before stopping them, and then pinch off the laterals above the first leaf, when they have made five or six leaves. When they have perfected their growth they may be placed out of doors during their season of rest. In the autumn they will require some of the old soil to be removed from the surface of the pots, and about one-third down the sides between the pot and the ball, and replaced with rich compost as above. When they are pruned they must be reduced in length according to the size of the house in which they are to be fruited, but ought not to exceed 7 feet in length. If they have been well grown they will bear a respectable crop of fruit the following year; but Vines one year old, cut down to one bud, and grown a second year, may be expected to do much better.

As regards varieties suited for pot-culture, none can surpass the Black Hamburg. The Frontignans also succeed well, and so does Chasselas Musqué, though it requires a dry atmosphere when ripening, or else it is liable to crack. I have also seen the Muscat of Alexandria do well, but I have not grown it myself. I would avoid the Golden Hamburg, as under the best treatment I have never seen it succeed in a pot. Any one with but a very small amount of glass, when they can command attention, may grow good Grapes from pot Vines, and derive much enjoyment from their cultivation.—QUINTIN READ, *Biddulph*.

A WORD ABOUT STRAWBERRIES.

IN reference to the communication in *THE JOURNAL OF HORTICULTURE* respecting the successful mode of growing Strawberries, by "Quintin Read," *Biddulph*, I beg to make the following observations. Although I fully agree with him in many points, I differ widely in others.

We grow a great many Strawberries here with great success. We devote about three-quarters of an acre to Strawberry plantations. Our kinds are as follow:—Keens' Seedling, Sir Harry, Sir Charles Napier, British Queen, Oscar, and the Elton.

I plant and manage them exactly in the same way that your correspondent states, with the exception of planting in the three-and-a-half-foot beds, and allowing their foliage to remain till spring. I have, for instance, a quarter of an acre of Keens' Seedling in one bed. These were planted three years ago 3 feet from plant to plant in the row, and the rows 2½ feet asunder. Last year this bed produced some very fine fruit, averaging about twenty-two to the pound. After they had done fruiting the scythe was introduced to perform that barbarous practice that your correspondent says has happily passed away. After the scythe the knife came into operation, in trimming and cutting every runner and decayed leaf away, leaving only the young leaves that were just bursting forth. The next

performance was to clear away the straw that was laid down to preserve the fruit from grit, &c. This was taken to the rubbish-heap and, with some pea-haulm and all the Strawberry trimmings, was set on fire, and all consumed together. The next work was to clear away every weed and runner that was to be seen; and from that time until the bed was littered down again for the protection of the fruit not a weed or runner was allowed to exist. By the end of October the plants were well stocked with fine healthy luxuriant foliage, and never as yet have they required any more protection than the garden walls surrounding them afford.

Now this practice has been in force for the last eight or ten years in this place, therefore I do not feel inclined to give it up so long as I meet with great success. For instance, the bed above mentioned yielded an extraordinary crop of fruit this season. On one occasion we picked two bushels at one time, and for three weeks little short of half a bushel was picked daily, and all of very fine quality.

The other kinds do equally as well in proportion. The scythe took its course again this season as usual. Now (the 2nd of November), the plants are nearly touching each other in the rows, many of them measuring 2 feet in diameter, while the crowns are firm, plump, and well matured.—J. B. C. P.

CALCEOLARIA CANARIENSIS.

THAT the character which many plants earn for themselves is as largely dependant upon circumstances as is the formation of the human character itself, becomes yearly more evident to those who keep an eye on the career of the various new varieties of plants which are dismissed from the careful scrutiny of the highest tribunals with first and second-class certificates.

In responding to the suggestion of your correspondent Mr. James Harris, page 333, regarding this *Calceolaria*, it could be amply demonstrated, if necessary, that "circumstances greatly alter cases;" and the sentence with which Mr. Harris concludes bears evidence that he is well aware of the fact. This knowledge any gardener who has practised in widely separated localities, differing vastly in soil and climate, must possess; and notwithstanding the slashing castigations which are so very commonly administered to floral committees and nursery firms for giving the weight of their authority to certain plants as being suitable for any given purpose, but which under some circumstances belie their character, it is productive in some minds of a charitable feeling towards the parties concerned.

My experience of *Calceolaria canariensis* would justify me in recommending it to all who wish to have a unique bed of yellow *Calceolarias*. Two beds of it here have this year been the admiration of all who have seen them. Not a single plant gave way during the intense heat and drought which we experienced throughout July and August; and when the heavy rains set in it stood the dashing much better than any of the others, and was gay a good while after they were all but flowerless in October. The opinion formed of it has led to every cutting being put in that could be had.

The beds in which it has done so well are well elevated above the surrounding level, and the soil is a rich open loam. Last season some plants of it that were planted in a damp place where the sun left it early in the afternoon, proved very similar to what is recorded of it by Mr. Harris. From this I conclude it likes a well exposed and not over-damp position. In pots it is one of the finest things I have seen, and yields an enormous crop of bloom; and for small beds it is likely, if it maintain its style of this year, to be most useful. Edged with blue *Lobelia* it is very telling, and being so dwarf the two suit well together.

It is exceedingly desirable when giving an opinion on our experience of plants similar to this, that the soil and position in which they have been proved should be named. I have learned to deal rather tenderly in giving an opinion on new bedding plants, having tried a vast number of some of the sections at least, and am well satisfied if one in a dozen proves worth growing. Yet, from former experience, I can easily believe that some which I have found next to useless here may be first-class in soils and climates the reverse of that in which I have proved them. As an illustration of

this, it may be stated that on the cold clay soil of Hertfordshire I always found *Geranium Improved Frogmore* far superior to *Tom Thumb*; while here, nearly on a level with the Firth of Forth, in a light deep loam and dry bracing air, *Tom Thumb* is far superior to *Improved Frogmore*. So, again, with some *Verbenas* which did exceedingly well on the cool clayey soil, but do no good here, and *vice versa*. It is no doubt with a knowledge of such facts that Mr. Harris pronounces so judiciously and cautiously on this *Calceolaria*; and I should wish to do the same. Were it necessary to illustrate any further, I might say that *C. Aurea floribunda* is quite second-rate here, while with Mr. H. it is first-rate; and so I believe it is in the west of Scotland, where the soil is heavier and they get more of the "Scottish mists" from the Atlantic. Hence it becomes very undesirable to pronounce sweeping condemnations with regard to bedding plants in particular, because pit plants are generally subject to circumstances more alike all over the country. One gardener looking at the merits of a plant through the influence of a certain description of soil and climate, might insist against the evidence of another who views it under circumstances the very reverse; and the two might battle about it just as reasonably as if they were to pronounce on its size while they looked at it through the different ends of a telescope. On this account our opinion, to be really instructive, should be accompanied with the nature of the soil and climate in which flower-garden plants are proved. Another point to be taken into account is that any given plant may, from causes which it would be difficult to name, succeed one year and not the next, so that we should not be in haste to judge it not suitable or otherwise even to our own circumstances.—D. THOMSON.

NOTES ON GLADIOLUS CULTURE BY AN AMATEUR.

I HAVE read with considerable interest the remarks in many of your recent Numbers on the cultivation and diseases of this attractive and favourite plant. As I have had the good fortune to have grown it successfully for many years, I venture to lay the simple process of my success before my brother amateurs, assuring them that there is less difficulty in cultivating the *Gladiolus* than there is in growing *Dahlias* or even choice *Kidney Potatoes*. I am the more emboldened to do this, because by a simple application I saved my plants this year and secured a good display of bloom. I ought to tell you first that my locality is a cold wet part of Lancashire.

Well, when I first saw the complaints this year in your pages that *Gladiolus*-beds were showing unhealthy symptoms of decay, leaves turning prematurely dry, &c., I looked at my beds and found many of the plants slightly affected at the tips of the leaves, and the leaves themselves of an unhealthy colour. I at once gave the surface of the beds a good mulching of old rich manure, and during droughty weather gave the plants lots of water, which, of course, percolated through the top-dressing; and I assure you the change in the colour and the substance of the leaves soon expressed the grateful thanks of the bulbs below, and in due course an ample display of bloom followed. However, to describe my annual course of treatment I ought to begin, as they say, at the beginning.

I was induced to invest in a dozen bulbs by a London seedsman when the price was a much greater matter of consideration than at present. I took them with dread, for I feared the management would be beyond my ability. Well, I had a splendid show of bloom, which was greatly admired by my envious neighbours, accompanied by the usual sage nod of the head and remark, "Oh, yes, they are all very well, but you'll see you can't keep them through the winter." After the blooming was over my plants remained verdant without the slightest signs of going to rest. Cold weather and frost began to appear, and yet no signs of the plants ripening-off naturally, as I knew they ought to do; and equally well I knew that if they did not I might say good-bye to them. So without more ado I lifted each clump and deposited the lump of soil, bulbs, and stems, unbroken, into the dry soil of an exhausted Melon or Cucumber frame, and had the gratification to see the stems

ripen and drop off in a week or two, and the still greater gratification to find myself the possessor of an abundant brood of young offsets from each root; and I had the yet greater gratification of dislodging and consigning to a proper place a number of wireworms which appeared to have selected for their winter abode, or rather for bed and board, the snuggest parts of each clump. My bulbs being perfectly dry and ripe were safely stored in bags until they showed signs of starting into growth again, upon which they were immediately potted, and in the spring turned out into beds again—beds I say, for the increase was three-fold of strong flowering bulbs.

For the sake of experiment, the following season I tried the effect of an immediate repotting and also replanting after the ripening-off in the frame; but the result satisfied me that the bulbs are the better for a short airing until they show signs of growth. Some show it sooner than others; but when they do show it then is the time to pot the bulbs and keep them gently growing until your beds are ready for them in spring. This plan has been with me so successful that I can confidently recommend it to my brother amateurs.

If I may venture to make a remark among so many learned doctors, who are now so sapiently giving their opinion on what they call the *Gladiolus* disease, I would say that in my humble opinion the *Gladiolus* is suffering from the overstimulating character of the feeding it has had for the purpose of counteracting the weakening effects of overbreeding. I would recommend a more plain, substantial, and healthy diet as the best means of securing a more healthy progeny, even if we amateurs should be called upon to pay the doctor's fees in the shape of an extra price for healthy bulbs.—W. W.

P.S.—I have been surprised to find how few ladies know the valuable property which the *Gladiolus* has of opening its bloom in water. I have seen more than one fair dame throw the stem away as soon as the first bloom faded, little thinking that a day's patience would have been rewarded with another glorious flower higher up the stem, and so on day by day for weeks of pleasure.

WINTERING BEDDING-OUT PLANTS.

Among the seasonable operations of the present time, is one that more or less engages the attention of every gardener—that is the disposal of the bedding stock. Every gardener who has much to do in the way of bedding, is at this time of the year put to various shifts from want of space, every inch of which is required, both for plants that are to continue under glass, and for those that are to be turned out shortly. Every one who reads the weekly notes of Mr. Fish will see, not only the difficulties under which he labours for the bestowal of an immense bedding stock, but the ingenuity with which he meets those difficulties. Whatever opinions may be formed by the ordinary reader of the contrivances he makes use of to clear the houses and harden-off the stuff, it is only the practised gardener who can thoroughly appreciate them, and of these only such as are in the habit of contriving for themselves.

It is very well to remind the possessor of frames and shallow pits, that he should get his plants into them so that he can harden them off by pulling the lights right off every day; but what is the use of such advice to those who have no such appliances, or, who, having them, find them already full to repletion? It then becomes necessary to look about for some other contrivance; and one of the most ingenious is that described by Mr. Fish, and of which I intend to avail myself, thanking him for the hint—that is, to dig a trench as if for Celery, and to lay sticks across it on which may be placed mats or any other covering. The plants may be packed closely together in the trench, and as bedding stuff seldom exceeds a foot in height, it is easily accommodated in this way; and while it is in a great measure protected from cutting winds, a slight covering will protect it from such frosts as we are likely to have at this time of the year.

But what I would recommend as most useful where such shifts have to be made, is coarse felt stretched on light wooden frames of a convenient portable size. These I have found excellent, both for keeping frost out of pits and

frames, and protecting plants when not under glass. Without wishing in any way to disparage the ordinary garden mat, which is indispensable, and useful for many purposes, yet I must say that felt is equally so, and for some purposes superior, as the frames covered with it are not so easily displaced by wind.—F. CHITTY.

ROOTS AND LEAVES.

(Continued from page 333.)

WHERE Vines grow in earthen-borders, which are one mass of putridity, little beyond fleshy-root-extension takes place. Very few fibres indeed appear at any time; the stems require less heat to cause the buds to swell and break; the growth appears small, but gross and long-jointed; and the leaves, though small at first, become something like a *Rhubarb* leaf. At this stage, if we examine the roots, we shall find little or no fibres, active or inactive; but the plant appears as if it depended on the humus absorbed by the root-stems for its nourishment, or is indebted for its nutriment to the atmosphere by which it is surrounded. Whether the plant owes its development to the nutriment collected by the roots without fibres, or to that collected by the leaves from the atmosphere, the leaves will flag when the moisture in the atmosphere is dissipated by the sun's influence rendering the parts about the leaves drier, and causing the leaves to perspire, or the water in them to be evaporated more freely than in cloudy weather. If the leaves flag under bright sun, it is an evidence of deficient root-action or a want of moisture in the atmosphere; but flagging is chiefly caused by the leaves evaporating more water than the roots afford them. If there be a quantity of fibres the case will be different. Instead of the plant having one mouth, it will have fifty; and it is only reasonable to conclude that a plant with fifty mouths would absorb more nutriment, and supply the wants of the leaves better in a case of emergency when extra food is needed, than a plant having only one.

Fibres, then, are necessary to a Vine's healthy development, and the extension of the main roots essential to the formation of fibres. There cannot be healthy development in a Vine, or any plant with a fibrous root, without fibres: hence the immense importance of their preservation, and the necessity of promoting their production. Rich soils hinder the production of fibres; poor soils increase their number. Plants grown in rich soil have more foliage and less fruit than the same species in poorer soil.

I am led to infer from this that fibres are the chief agents in the production of fruit-buds; and although I am but partially prepared to prove it, I am persuaded that they are the sole agent employed by the roots in their production. But we were considering the annual reproduction of fibres. I contend that all plants do partially lose the old fibres annually, some plants oftener. Superficial evidence alone is forthcoming in abundance to prove the fact, without calling to our aid any internal evidence at all. We give warmth or bottom heat to plants at the commencement of forcing, keeping the atmosphere comparatively cool to induce root-action before leaf-development commences. What necessity is there for this extra stimulant to the roots if their extremities are prepared to absorb nutriment on the expansion of the buds? Nature gives no such stimulant. It is a point, in fact, that proves the roots have not the requisite elements, lying dormant and only needing the expansion of the foliage, to call them into activity. In all cases of repotting the cultivator finds a quantity of dead fibres in addition to the growing, and attributes the presence of the dead fibres to an unhealthy root-action; whereas such is not the case, for, if there is a quantity of live fibres in addition to the dead, it is evident that what suits them would suit others. Sour soil very often causes the destruction of all the fibres of a plant; but that has nothing to do with the periodical decay of the fibres, being simply a medium in which the fibres cannot extend themselves.

Although the fibres are of so much importance to vegetation, there are cases in which their removal, instead of being hurtful is highly beneficial. Mr. Rivers actually destroys fully half of the fibres of his orchard-house trees every autumn in the process of top-dressing. At page 30 of his

"Orchard-House" he thus describes his practice:—"Take out a portion of the soil, 5 or 6 inches in depth, and about 4 inches in width, all round the side of the pot, leaving the central mass of roots undisturbed. A portion of the mould may, however, be picked out from among the mass of fibres with advantage, as fresh food can do them no harm," &c. Now, would so practical a cultivator destroy annually the points of the fibres if he knew that Nature demanded their preservation? He must have known the contrary, and so anticipated Nature by helping her to do at once what she would have done herself from the fall of the leaf to the commencement of growth in the ensuing spring. But Mr. Rivers is careful to preserve the woody portion of the fibres: it is from these, which may not improperly be termed ripened roots, that the fibres are emitted in the spring. Neither does he destroy the fleshy roots, from which the fibres on their first formation are emitted, but he leaves them entire or undisturbed at the bottom of the pots, and he rams the fresh soil, so that no root can run easily in it without emitting fibres. The same is done with Strawberries in pots for forcing, the object in both cases being to prevent the fleshy roots from extending, and thus to favour the production of fibres. Unless the soil in a Strawberry-pot is pressed very firm, the fleshy roots that strike from the root pass through the soil and out at the pot-bottom without emitting so much as a single fibre on the way. If, however, the roots are arrested in their journey by coming into contact with the sides of the pot, fibres are emitted, but only there; whereas the object is to fill the whole of the soil with fibres, and thus give the plant as many mouths in a six-inch pot as it would have when planted out and having roots penetrating to 2 feet deep.

The same appears again with any plant under pot-culture. An annual potting and a few after-shifts are all that is necessary to supply the wants of a plant. The annual potting is accompanied by a disrooting and an addition of fresh compost. Geranium-growers disroot so much annually as to necessitate the placing of the plant in a smaller pot. They one and all do precisely the same as Nature herself would do were she left alone. They limit root-action to a given space, and supply the wants of the roots in that space, obviating the necessity of their having to run about in quest of nutriment. In nature it is the reverse. The fibres are formed at or near the stem in the early stages of a plant's development; but after a time they are present at the extremities of the main roots, and where are those fibres that were formed near the stem of the plant? Have they become large roots with numberless fibres at their extremities? No, the large roots are but few in number; but had the fibres extended proportionately with the increase of the head, they would have been a multitudinous cluster of large roots extending from the stem in all directions. As it is, however, the fibres have not become large roots nor are present in the soil. The head has extended and shut out the rains from them; their part in the vegetable economy is accomplished, and they perish. But Nature does her work gradually, and fresh fibres are formed in other directions simultaneously with the decay of those first produced and now become useless.

I shall not pursue the periodical decay of the smaller fibres any further, for the materials at my disposal are so numerous that to recite all would extend this communication too much: but I must state that bulbs lose their roots annually, which are simply fleshy roots, identical with the fibres of woody roots which decay periodically, though very far from annually. If the roots of a Peach or Vine be examined after the leaves have attained their full size, a quantity of dead fibres will be seen, and from almost every division of the fibres new spongioles will be found either emitted or in course of being produced, evidently destined to supply the place of the decayed. Mark, it is the small fleshy fibres that decay, and not the wiry woody part. There are exceptions to all rules, and tree Ferns appear not to lose the extremities of the root except from accident. They always have some dead roots, but what I mean is that new roots are emitted direct from the stem, and travel a great distance without losing any part of their extremities, and when the point dies the root does so entirely, new roots striking out direct from the stem to supply its place. Roots of all kinds have a periodical discarding of some of their

parts; in a bulb it is the whole, in a tree the fleshy parts of the fibres, and herbaceous plants change them entirely throughout their whole length. An evergreen, even, undergoes the same process, but more continuously than periodically.

The dying-back of the fibres is necessary to the existence of the plant, for if they continued to grow year after year without throwing off any of their parts, the roots would become larger than the head, whereas they are on an average only one quarter of its size and weight. Another reason is, that if the fibres passed but once through the soil in which they are situated, they would leave a quantity of unexplored matter behind them, and when once out of it they could not return to collect the food it contained. But by renewing the fibres the soil is penetrated in all directions, and all the elements essential to the development of the plant are pretty much exhausted, so that a plant does not succeed well on the same ground after the growth of another of the same species.

Before leaving fibres allow me to add a little evidence in support of my opinion—"Fibres are the chief agents in the formation of fruit-buds or a plant's productiveness." Presuming that we have two fruit trees, both seedlings, and we allow one to grow freely without any curbing or checking of its development; and suppose we treat the other in an opposite manner, transplant it annually, and instead of letting the roots run where they will, curtail or limit their action: the one, as we all know, will become a large tree and the other a dwarf; the one is barren and the other fruitful; the one has roots the thickness of a finger, but the other has them smaller than a grass stalk. Both, however, have fibres, but in the tree left to Nature these can be counted, whilst in the other they are numberless. But the fibres, I may be told, are due to transplantation. Certainly transplanting increases the fibres; a plant that had one spongiole before transplanting will have fifty in the following season, and these are unlike such as would be produced by the untransplanted plants—they are smaller, have shorter divisions or branch more, and collect food slowly, whereas, in the other case they collect nutriment rapidly, and this having a straight channel to run in is transmitted to the stem and leaves with greater rapidity, and the growths made are strong and anything but branching—they have the character of the root. But the transplanted subject makes short growths, is stunted, having also the character of the root.

To recapitulate: Free root-action induces free growth and unproductiveness; transplantation promotes the production of fibres, fibres create stunted growth, and stunted growth gives bloom-buds. In this way we have Apple, Pear, Plum, and Cherry trees the size of Rose bushes, producing fruit equally fine and large with those grown on large orchard trees that are years before they come into bearing. The former are made to produce fibres by annual or biennial transplantation, but the latter have their freedom and make growth in proportion to the food taken up by the roots. The aim of a plant is to perpetuate its species, and it has the power of adapting itself to circumstances. If its seeds are dropped in a rich soil it is longer before it produces seeds, and if they are placed in poor ground it grows slowly, has innumerable fibres penetrating through the soil, and produces seeds in half the time and when half the height of its congener. There are more fibres on the latter than the former, and fibres are the cause of fruit-buds being formed.

Further evidence is forthcoming in the case of a luxuriant-growing tree and barren. Pruning and every other means avail nothing to overcome its unproductiveness. Root-pruning, however, is resorted to; the straight and broad channels are made crooked by the emission of fibres, and the barren tree becomes fruitful. Again, we have two plants (fruit trees) and wish to force both, but we will plunge one in bottom heat and keep the atmosphere cool for a fortnight or until root-action commence; the other we keep cool during that time, when we place it in the same atmosphere with the other, with or without bottom heat. At this stage the one has a quantity of newly formed fleshy roots (according to its kind), which have reached the sides of the pot, and the presence of which the gardener hails with delight, but the other has no roots beyond those of the previous year. They both commence growing, and the first is strong, and the growth close-jointed but not gross; the

growth of the second is small though rapid, the leaves small, thin, tissue-like, and altogether unpromising. After both have grown a foot, let us examine the roots. That pot plunged in bottom heat is one mass of thread-like fibres, but the other has only a quantity of fleshy roots, the same as that plunged had when forcing was commenced, or rather when top heat was applied. We leave them growing and it comes a sunny day; the first holds its head boldly to the sunbeam, but the second shrinks back and flags. However, the weak plant in time gains strength and makes wood equally strong with the tree that has been in the hotbed. Looking at the roots of the former we find a quantity of fibres. That is enough.

Now, suppose these plants were Figs. That with fibres will have fruit nearly at every eye; but the other has none at any of its eyes except a few at the tips of the branches. What is the difference between the growth of the two? The first had fibres to begin with, and it formed fruit-eyes at every joint; but the second had no fibres, and it formed wood-buds only until fibres were emitted. If we suppose they were Vines, the results are precisely the same: there are no fruit-buds formed when the growth is made by the fleshy roots only, but there are when it is made after the emission of fibres. Surely the evidence is conclusive.

Stopping the branches is not the direct cause of the formation of fruit-buds. All stopping simply limits the action of the roots, induces the formation of fibres, and if it does not the eyes below the stopping start into growth. A wood-bud has been formed, for buds are formed with the leaf, and not afterwards as is generally supposed. After the leaf is formed, the eye at its axil is either a wood or a bloom bud, and no stopping whatever can transform them either way. Vines will show fruit on green laterals if the eye forced into growth is a fruit-bud. No hardening or ripening of the wood can form fruit-buds, but they are solely attributable to the peculiar condition of the roots at the time of development.

The production of fibres being so essential to the well-being of a plant, their preservation and production are matters of import to all cultivators. I may, therefore, tender a few humble remarks and hints as to their preservation or removal.—G. ABBEY.

(To be continued.)

CENTAUREAS ARGENTEA AND CANDIDISSIMA.

As *Centaurea candidissima* is unquestionably one of the most important additions made to our flower gardens for some years, the advent of a kindred species with foliage more beautifully cut may be regarded as another advance in the path of out-door embellishment; and *C. argentea* has been ushered in with a high name as likely to eclipse its predecessor. Its claims to this distinction as a potted plant may, perhaps, be admitted, though I am by no means certain that they will be so; but what little I have seen of it out-doors inclines me to place it many degrees below *C. candidissima* as an effective plant for the flower garden; in fact, judging from the plants we have here, I should say it is not so good as *C. gymnocarpa*, of which there is a bed or two at the Crystal Palace, and which I see a correspondent at page 213 notices. I quite agree with him as to the good effect produced by *C. candidissima* and *Amaranthus melancholicus* in one bed, although I was otherwise well pleased with the main features of the planting.

Leaving this subject, however, might I ask through the pages of your Journal which is the best *Centaurea* for bedding purposes? Mr. Thomson in a former article mentioned *C. ragusina*, a species I am not acquainted with. Is it the same as *C. candidissima* or not? The flower-gardening public must, I am sure, be much indebted to Mr. Thomson for his excellent article on the propagation of this highly desirable genus, which I hope to see extensively grown when it can be had in sufficient quantity; but in the meantime I should like to learn from those who have grown all the species which is the best. For my own part I am well content with *C. candidissima*, and its appearance here far excels that of *C. argentea*; but if others think differently let them record their opinions. The small-leaved *Cerastium*, *C. tomentosum*, was by some expected to be eclipsed by its

more robust kinsman, *C. Biebersteinii*, but the former still retains its place; and what I have seen of *Centaurea argentea* inclines me to think that it will still less approach its forerunner in merit.—J. ROBSON.

HEATING A GREENHOUSE FROM A DINING-ROOM FIRE.

A *Devonshire Vicar* would feel much obliged by information regarding any effectual plan for making use of the surplus heat from a dining-room grate (by means of hot water or air), in warming a greenhouse situated at the back of the fireplace, and on the same level as the room. Are there, for instance, any grates with boilers attached, from which pipes could be carried, which would not be a disfigurement to the room?

[If the greenhouse is small, a square plate of iron, fixed at the back of the grate, and open to the greenhouse, and black on both sides, would, with the heat of the chimney, keep out frost, if the fire was banked up at night on the occurrence of cold nights.]

This could be done better with a boiler at the back of the grate, but we question if you could have one so made without an order. There are many stoves with a boiler at the back and one side, but that would not be so elegant. If at the back it would be best to have a close boiler fed with water from the pipes in the greenhouse. The pipes must not be below the boiler, better above it; but you will have to confine them chiefly to the back and ends if there is a doorway. As most dining-room grates are manufactured in pieces, a small boiler might be formed at the back, and one side open to the greenhouse, where the pipes could be fixed. We remember one so arranged, and it would have done very well, but the fire in the room was not always used, and it was considered a grievance having to kindle a fire there when not otherwise wanted. In a cold night coke was heaped up round the boiler, and a plate of iron placed in front to prevent too rapid combustion.]

STEPHANOTIS FLORIBUNDA FRUITING.

Is it not rare for this *Stephanotis* to fruit in England? I have fruited it before, at Cron Castle, but the fruit was small, and did not come to perfection. Now, I have a plant with seven fruits on it measuring, on an average, 5 inches in length, and 8 in circumference. The fruit is of a conical shape, the colour a light green. Will it get much larger? What colour will it be when ripe? and is the fruit eatable? When I received this plant in December, 1862, it was in a 32-pot. I have shifted it on, and now it is in a No. 2-pot and trained on a wire globe.—OLIVER MORRIS, *Tobners, Hertford.*

THE VARIEGATED ARABIS.

SOME years ago a discussion took place in the pages of this Journal about the name of this highly ornamental plant, some calling it *Arabis lucida*, others *A. albida*; but I believe that commonly the specific name has been dropped, and the plant has been well known as the Variegated Arabis—a name at once easy and every way sufficiently expressive so long as only one variety was in cultivation. I have heard, however, that another feature has been given to this useful and compact-growing plant. The pale yellow, or rather cream-coloured, edging of the old variety is said to be turned to the more golden lacing of the best of our Golden Geraniums, or the yet more bright hue of the Gold-leaved Holly.

If this really be the case, the plant will in many instances supersede the Geraniums of the same hue, as it is perfectly hardy, and in habit as compact as could be wished for.

I confess, however, that I have not yet seen this Arabis, and possibly it may only be a slight improvement on the old one, or merely the latter grown under circumstances more favourable to its becoming more of an amber hue. I have had the old kind for many years, and now and then a plant or part of one will assume the normal form, and the coarse green foliage of the original parent will appear; but it is less liable to run into that condition than many other

variegated plants, and, taking it altogether, it is a beautiful appendage to the flower garden. Still, if the plant has undergone further improvement, and it has gone forth to the world attired in a yellow jacket, I for one shall be happy to learn where it is to be obtained.

Perhaps some of your readers will enlighten us on this subject, and describe what the improved plant is like and other relative matters, omitting if they choose all mention of the name, which may or may not be one or other of those mentioned above. The "Golden-edged Arabis" is expressive enough, and if it does in reality exist, I hope that its possessors will not keep it unannounced.—J. R.

SOME GARDENS WORTH SEEING.

CORNWALL.

Name.	Proprietor.	Gardener.	Station.
Pentillie Castle	A. Coryton, Esq.	Mr. Edwards	Saltaash.

—H. C. K.

[We are obliged for the above as well as for all others which have been forwarded to us, and we hope that such lists will continue to be sent. These lists need not include only first-rate show places, but might very advantageously specify gardens on a smaller scale distinguished by the taste with which they are arranged.]

GARDENERS' NAMES FOR FLOWERS.

"WILTSHIRE RECTOR" at page 328 of THE JOURNAL OF HORTICULTURE says that he is quite sure that well-educated gardeners will say Amen to his remarks on this subject. I am afraid that I am not sufficiently educated to do so. I have generally found gardeners (entitled to the name) anxious to pronounce the names of the flowers and fruits they cultivate correctly, and they usually succeed in doing so as well as may be expected.

To instance the "beer-loving fellow," or the one who would offend the delicately correct ear of his lady employer by calling her Cyclamens "Sickly uns," and whom she no doubt dignified by the title of her head gardener, and possibly remunerated at the munificent rate of 10s. or 12s. per week, is about as fair as it would be to form an opinion of the eloquence, &c., of clergymen generally by listening to the men we occasionally hear holding forth by the waysides and corners of streets. The Géant des Batailles Rose and the Bon Chrétien Pear are well-known varieties, and I admit to having heard them variously pronounced, but I have never heard anything applied to them approaching to "Johnny Bottle" or "Bun Christian;" and I feel quite sure that the "beer-loving fellow" must have been quizzing his reverence, who did not perceive it.—G.

VARIA.

I AM always glad to see the letters from amateur correspondents which every now and then appear in your Journal. Much good may be done by persons residing in different parts of the country sending up simple statements of their successes or failures in horticulture. It is, in fact, only by this means that any certain conclusion can be drawn with regard to a new and doubtful phenomenon, such as this *Gladiolus* disease, which is now occupying so much attention.

Although both my experience and the rectory garden, from whence it is derived, are small compared with the resources of many of your correspondents, perhaps you will be glad to get some jottings from the far west.

In the first place, then, with regard to the disease in the *Gladiolus*. I have from seventy to eighty bulbs altogether: about forty of them are *gandavensis*, and it is in them alone, and only in two bulbs, that the disease has appeared. The

bulbs were brought from Jersey in the autumn of 1860: this was, therefore, the third season I have had them under my care. As they increased rapidly, I determined this year, for the first time, to try some in the peaty soil of a *Rhododendron*-bed. This soil was brought in some years ago from the downs by which we are surrounded, and consists of a stiff, black, fibrous peat, used by the neighbouring cottagers for fuel until they were prohibited from so doing. In this soil *Rhododendrons*, *Azaleas*, &c., flourish and attain an immense size. Here, then, among, or rather in front of, the shrubs I planted some *Gladiolus gandavensis*, while others were placed, as in former years, in a flower-bed well manured with rotten leaves and the remains of an old *Cucumber*-bed. The latter flowered splendidly, and I expect shortly, when I take them up, to find a rich harvest of sound and healthy bulbs. The former also flowered well, but in two instances the disease appeared, exactly as described by several writers in your Journal. Fearing the possibility of infection I took up one. The old bulb had as usual decayed away; but the two new ones found upon it were evidently diseased, not having attained more than half their ordinary dimensions, and the outer scales falling off soon after they were taken up, leaving the inner solid portion white and naked. I cannot, however, detect any rotten part similar to that which appears in the diseased tubers of the Potato. My first impression, when I saw the leaves withering, which took place in the hot dry weeks of July, was that the bulbs wanted water. They were liberally supplied, but to no purpose. I leave these facts to the consideration of "D., Deal," and others who are trying to get some reliable data concerning this curious disease.

Your correspondent, Mr. G. Abbey, in his interesting article on "Roots and Leaves," page 332, says, speaking of a leaf-cutting of the *Gloxinia*, "the leaf imbibes moisture from the atmosphere." Can he give us any proof of this? Prof. Henfrey in his "Outlines," published in 1846, page 101, says—"It has been sometimes imagined that leaves also possess the power of absorbing fluid, especially in those plants which live for a long time without roots. . . . It may be assumed that absorption is never, or at least but seldom, exercised by leaves in a normal condition." Lindley, however, in the latest edition of "School Botany," page 193, says—"It is by means of this apparatus (stomates) that leaves absorb water and gaseous matter from the atmosphere." Which is right? Is this case of the *Gloxinia* leaf one of those exceptions of a leaf in an abnormal state, which even Professor Henfrey would seem to allow may possibly occur? Or does Mr. G. Abbey agree with Lindley, and suppose that leaves in their ordinary condition absorb moisture through their stomata, instead of those orifices being simply used for the purposes of evaporation and exhalation? Would it be troubling him too much to ask him for further information on this point?

We, who live in the west country, are supposed to pass half our time in a sort of warm vapour bath, produced by constant mists and fogs. There is some truth in this commonly received notion. Even this year we could not be said to suffer from dryness or heat, though we thoroughly enjoyed the luxury of a few really hot, dry days in succession. But even our climate seems to be too dry for *Mimulus cupreus*, which, though very pretty in itself, is useless apparently for bedding purposes, on account of requiring so much water. It will make, no doubt, a useful ornament in the conservatory.

I failed in the *Amaranthus melancholicus* by putting out the plants both too small and too soon. Those which were kept in the greenhouse grew into strong, bushy plants, and on an upper shelf close to the light were extremely beautiful. They were fed with a very strong solution of tank manure, and seemed always to thirst for more. I was obliged about a month ago to turn them out to make room for other things, when they soon succumbed. But with the experience of this year I hope to be more successful with them out of doors next season.

Humeas which stood out unprotected last winter, were finer this year than those kept in the greenhouse, attaining a height of 7 to 8 feet, and branched in proportion. These also were in the peat above mentioned, as well as some *Tritomas*, sown in the spring of 1862, now large plants, which I hope will flower next year.—S. L. G., Cornwall.

MITRARIA COCCINEA.

(SCARLET-FLOWERED MITRARIA.)

Specific Character.—Plant a shrub. Stems climbing. Leaves opposite, small, ovate, acute, serrated. Flowers axillary, solitary. Peduncles slender, about 2 inches long. Bracts mitre-formed, covering the calyx. Calyx five-parted. Corolla of a brilliant scarlet; tube ventricose, $1\frac{1}{2}$ inch long; limb bilabiate; upper lip with two rounded lobes; lower lip three-lobed, lobes smaller than the upper ones. Stamens four, exserted.

This is a most ornamental climbing shrub, having the habit of *Columnea*. It is a native of San Carlos de Chiloe, and was introduced by Messrs. Veitch & Son, who received it from their collector, Mr. Lobbs.

The leaves are small and neat; and the flowers, of a vivid scarlet, hanging gracefully on long, slender peduncles from the axils of the leaves, give it when it bloom more than an ordinary share of attraction.

This genus, *Mitraria*, was founded by Cavanilles; the name being derived from *mitra*, a mitre, in reference to the mitre-formed bractea which covers the calyx; and is a very different plant from the *Mitraria* of Gmelin, which is a *Barringtonia*. The subject of our present woodcut is the only species at present known, although it is not improbable but subsequent collectors may yet meet with other, and, perhaps, still more valuable members of so beautiful a genus.

The cultivation is easy. If the plant be grown in a pot, lay abundance of broken crocks at the bottom for drainage; and for the soil, use a mixture of two parts leaf mould, one part light rich loam, and one part peat; but if it is planted in a border, any light rich earth or good vegetable mould will suit it well.

Increase is effected by cuttings of the half-ripened wood, planted in pots of sand and placed under a hand-glass.—(*Paxton's Magazine of Botany.*)

TRENTHAM.

(Continued from page 356.)

Passing along the east aspect of the west wall, which is also devoted to Pears, as on the other side of the garden, but without any glass case; here, too, there was a good crop, showing that the bloom against the wall resisted the frost which was found so injurious to the blossom in the open though sheltered quarters, and on trellises and arches. Here also the trees had been side-grafted with many kinds. Under the glass case, the stems and branches had a brownish colour, having been painted with a composition of soft soap, sulphur, cowdung, and clay. Anon we reach the long range of houses with their appropriate buildings behind, which I have already noted extending from this western boundary

near to Mr. Henderson's residence. Between this and the Pear-trellised walk are placed the houses on the west side of this main kitchen garden.

We commence, then, at the west end of this range, commonly called the Muscat range, and enter first into a long house filled with young Vines, of which the accompanying section is from memory, only we think that the inside border was only partially made. We introduce the section chiefly to show the system of border-making, the border inside and outside being entirely above the ground level. The house is 11 feet in height from the path inside; the pathway is 4 feet wide; the front is about 2 feet above the sill, which rests on pillars, so as to give free egress to the roots outwards. The width from back to front is 16 feet. The sill, if we recollect aright, is of wood, eased in zinc to protect it from the damp earth. The outside border is 12 feet wide, and it will slope from the sill to the front, where it will be shallower. At the back, close to the sill, it will be $2\frac{1}{2}$ feet deep, with 18 inches of large stones and rough rubble underneath. The soil was the best thin top-spit, with a fair allowance of boiled bones. Some of the bones that we examined were quite sweet, crumbly in the centre, and the roots passing through them. The outside of the bank of earth above the stones consisted of the roughest pieces of turf, and the air passing between the seams would render them very dry in hot weather. This very fact would have a tendency to send the roots back into the more moist soil behind. It was pleasing to find Mr. Henderson practising so largely, and not by any means in this house alone, the bit-by-bit system of border-making, which has frequently been recommended in these pages. This is done, not merely because part of a border can be more easily and conveniently made than a whole one, but because this bit-by-bit system contributes so much more to the continued luxuriance and fruitfulness of the Vines. When the roots have thoroughly permeated the yard width of the border as shown in the section, then 2 or 3 feet more will be added in a similar way. Had the border been made to the front at once the roots would have run along to the front, though there had been comparatively few lateral rootlets; and before these interlaced the whole border much of the nourishing properties of the new material of the border would have been dissipated by decomposition and evaporation. Making a large border at once, and especially out of doors, seems somewhat analogous to the farmer turning a flock of sheep into a field of Turnips, and allowing them to run and nibble where they may. The piece-by-piece border-making may be compared to folding the sheep, so that every available scrap of food shall be made use of, and a demonstrable compensatory influence be left behind them.

The young Vines had been planted inside near the front of the house in July, 1862, and were now strong rods, reaching to and beyond the top of the house, and were fast taking the desirable brown colour. The laterals, that had been somewhat freely encouraged to promote root-action, had been removed to increase the ripening of the wood and the plumpness of the buds. We were pleased to find, that for mere strength of stem in young Vines and Vines in pots, Mr. Henderson depended more on a free growth of laterals in the early part of the season than on mere length of shoot and stem. These Vines he proposed shortening considerably in a fortnight to concentrate the strength near home; and in winter or spring he would shorten back to about 5 feet from the border. If he has not already shortened

these canes it would be a good chance to try removing all the buds above the requisite height, and allowing the shoots to remain at their present length until the leaves had fallen, and then to compare them with those that were shortened as proposed. Few men have such opportunities as Mr. Henderson of making and testing such experiments, even if they had a good share of his enthusiasm. A few Vines were bearing a bunch or two, and among these the Gros Maroc, with large oval berries of a dense dark colour, which it is supposed will be first-rate in February or later. This we had not seen before, but if it stand the test of experience it is likely to be better known. The back wall of this house is clothed with Guavas, Camellias, Citrons, Oranges, &c.

In making a border of such fresh materials and planting at midsummer, Mr. Henderson told us there was a risk of having too much bottom heat. That we can well believe, for in a border which we once saw made in the beginning of September, chiefly from thin parings from a pasture with the grass on, a thermometer placed at 15 inches deep rose to 110°; and, again, when once we noticed Vines raised in October and replanted into such material that had been thrown together for a few months to drive off the rankness, the gardener, before covering the border with dung to throw a little heat in, found that a little litter was all that was required for the border, by feeling that the trial stick was quite warm enough to encourage fresh rooting directly after transplanting. We mention this that such fresh borders may be examined, and, perhaps, they would be still warmer if a good quantity of bones were used.

The next house in the range is one of the finest to be met with, and was put up by Mr. Fleming in 1858. It is 140 feet in length, 19 feet in width, inside measure, 12 feet high at back from the floor, and 2½ feet high in front. The back wall is built in the usual way. The front is supported by brick pillars 14 inches by 9, to the depth of the Vine-border. These pillars are headed by a stone cap, into which the mullions, or studs, between the front lights are dowelled, the upper ends being tenoned into the wall-plate. These studs are 5½ by 4 inches. The whole of these upright lights are hung on pivots 8 inches from the top, and are all opened, less or more, by a movement-rod of 1½ inch, curved stay, and winch; the whole front being opened by three of these movements, any one-third being done at once, and with or without the others in succession. The roof is formed of wide ridge-and-furrow, running transversely on the rake at an angle of 21°. There are twenty-six spans in the length. The height to the ridge of span would be about 16 inches. The ridge-and-furrow terminates about 26 inches from the back wall, being finished there with a rail, the openings beneath glazed, and on this rail rests in front a narrow light of the above width all the length of the house. By a patented screw apparatus fixed against the back with movement-rod, curved stays, &c., the whole of this glass coping may be raised from 1 to 20 inches by three lifts, or three sets of instruments, each managing, therefore, about 47 feet. The chief peculiarity of the house has yet, however, to be mentioned. The sides of the span of the ridge-and-furrow do not join together at top in one ridge or apex; each has its own, and there is a space of 4 inches between them covered by a moveable ridge-cap, which when raised can admit on each side from the smallest amount up to 3 inches of air. In the opening of each ridge, at regular distances from top to bottom, are five brackets to which hinges are attached at the bottom, and the top of the hinge is attached to the ridge-cap, and works on the principle of a parallel ruler. The top hinge of each ridge is connected by stays, joints, and rods to the same apparatus against the back wall, and three of these will at three movements lift the caps of all these ridges. The first time we noticed moving the caps of a ridge-house for air-giving, was in a small span-house at Messrs. Lee's, at Hammersmith. A simple lever elevated the cowl, but carried it at the same time lengthwise out of its usual position.

Most people would have imagined that 20 inches at top, and as much or more in front, would have been air enough for common occasions. If, as some contend, the admission of air equally all over a house is an essential of success, then there can be no question, not only of the ingenuity but the great usefulness of such a mode of lifting the ridge-caps. Mr. Henderson assured me that with the most ordinary care burning and scalding were next to impossible in such a house,

as in the hottest days the temperature within could be kept down so as not to be above 2° or 3° warmer than the air out of doors—a feat which he could accomplish in no other house under similar circumstances. We would not suppose for a moment that Mr. Henderson would thus wish to assimilate the inside to the outside temperature in a hot day; but there can be no question that the means of giving plenty of air and in the best manner is one of those important questions to which we can scarcely attach too great consideration.

The gutters of the ridge-and-furrow are lined with lead, and empty themselves into an ogee iron gutter, whence the water is conveyed to a large tank beneath the border, on the west end, inside the house, and as hot-water pipes pass through it, the heat of the water will generally average 80°—a matter of great importance as tending to the health and luxuriance of all tender exotics. We can fancy the run that would be made on this reservoir of warmed soft water. From this and the heating apparatus the nice clean bathroom of the young men behind is constantly supplied with water in all stages from cold to hot.

The somewhat heavy roof is supported about the centre by neat iron columns at every second gutter, and tied by neat transverse arches between. There is also a dwarf trellis in front of the back wall for such things as dwarf Oranges, &c. The back wall was covered with Figs, Shad-docks, &c., but the Vines did not let them have overmuch light. The Vines were chiefly Muscats doing well, the youngest, especially, having massive bunches, and there were besides, some late Black Grapes in fine condition, among which were very fine specimens of Barbarossa, huge in bunch, large in berry, and very black. Many facts tend to confirm us in thinking, that to have the Barbarossa fine it requires as much heat as a Muscat. Part of these Vines had been lifted and replanted inside in February—in fact, the moving of Vines in the midlands seems nothing thought of, and yet the crops do not seem to suffer. A small border only has been made outside, and that would be added to when the Grapes were cut.

We next pass through two Peach-houses, first and second, bare of foliage, and waiting an opportunity for pruning and washing. The back walls are covered, and there is a wide circular trellis in front, from which an arch goes to the back wall at every 12 feet as in the narrow houses. The pillars that support the back of the flat circular trellis are 4 feet in height, and 4 feet from the back wall. At that height in such lofty houses the back wall is not injuriously shaded. After pruning, the trees are well washed with soap and water, the surface soil renewed, and the wood all painted with a mixture of clay, cowdung, sulphur, tobacco juice, and a little glue to make it stick all the better. A good deal of last year's painting was still sticking on the wood of the trees, which were in fine condition for bearing, leading to the conclusion that many of our preconceived ideas as to absorption and perspiration through the bark may be somewhat modified in practice.

We have now traversed the boundaries of this main garden, and arrived again at the main central walk from north to south in front of the garden residence. On the west side of this walk, farther south, in an enclosed square, is situated the Pine ground, backed and fronted with an upright house for Vines, each about 80 feet in length. The house on the north side, called the Pine-ground Vinery, has its north wall mostly concealed by a circular trellis over a walk, covered with Roses, Honeysuckles, Clematises, &c. The house is planted inside, back and front, with Hamburgs in fine condition, intended for use before and about Christmas, and which have received scarcely any assistance from fire except when in bloom. A little fire heat would be given in September and onwards to ripen the fruit thoroughly and prevent anything like damp affecting them. Nearly in a line with this house westward were four lean-to houses all cleared of fruit. The house that is south of the Pine ground is called the Basin-house on account of a basin of water in front, which here interrupts the continuity of the Pear-trellis. It is backed on the north by wide glazed sheds, or greenhouses, very handy for potting, keeping back Pines, and setting plants in for many purposes. The Vine-house itself was planted with a mixture of Muscats, Lady Downes', Hamburgs, &c., and all doing well. Some-

Lady Downes' in fruit were patterns of symmetry and colour; and Hamburgs on the back wall were large in bunch and berry, and exceedingly well coloured. We noticed also what we have often noted before, that the bunches concealed from the full glare of the sun by the thickness of a leaf, were rather deeper coloured than those more exposed. Though there was the usual rod in front, $4\frac{1}{2}$ feet in height, with bunches and shoots from it all the way, still there is in these houses a great amount of light that reaches the back wall. I may also mention, that in addition to sulphuring the pipes, the whole of the back wall of this house and some others was well covered with sulphur. A bright sun would be sure to bring out some of the fumes and keep red spider, &c., at bay.

The Pines were looking well, young and old, succession and fruiting. Some fine fruit were ripening, and there were all stages from starting to swelling. There are three ranges, each about 80 feet in length. All are well supplied with hot-water pipes for top and bottom heat, and the former are well supplied with evaporating-pans. The two front houses are pits without any path in them. The back range is a low house, half span or deep hip at back, with wide path under it. This house is 18 feet wide; 12 feet is devoted to the Pine-bed, and 6 to the pathway. The Pine plants as a rule were in pots as being more manageable, and were distinguished for compact sturdiness, and thickness and hardness rather than length of leaves. The path on the floor and the shelves at back were supplied with fine plants of Vines in pots. In other houses and pits across the brook hundreds, nay thousands, of Vines in pots are grown in a superior manner, either for fruiting in pots, when more room is given them, or for planting out, when they are grown more thickly in nursery fashion.

Before leaving this garden we may state that we noticed many heaps of those tarred wooden covers we described at Keele, ready to be used for keeping the wet from the borders of either late or early Vines, &c. Useful at all times, they must be peculiarly so in the general climate of Trentham. Several questions have been sent respecting these covers; and if we answer them wrongly we trust that Mr. Henderson will correct us. 1. Do you use these covers? No, because we do not possess them; but we have recommended them for this purpose, also others for covering pits and frames, as the most economical in the end. We commend our young inquirer for "keeping his eyes open;" but he will generally find it best not to open his mouth too wide, so as not to frighten an employer with too many wants at a time. 2. Are such covers better than tarpaulin, oiled cloth, &c.? Decidedly so, as to economy of cost, and as to economy of labour; for a little litter, a few logs, or a few bricks or pots, will keep them from the ground, and we have known them in use for a dozen years and seemingly nothing the worse. 3. Would you recommend using the boards from the saw or planed before tarring? From the saw, if at all smooth-cut; if to be made nice and painted, plane the wood previously. 4. Are the slips down the joints essential, and what are the best sizes? The slips are essential, and they save all rabbeting of joints. We are not sure as to size; but were we to make covers 4 feet wide and 4 to 5 feet long, we would use boards three-quarters of an inch thick. We would have three cross-pieces underneath, 1 inch thick and from $3\frac{1}{2}$ to 4 inches wide, one at 6 inches from each end, and one in the centre, to fasten the boards to. Along each joint we would then tack a slip of half-inch wood 2 inches wide bevelled at the edges, and then neither heat nor cold would ever make open seams on the top. We would paint all over twice with hot tar, and have it well dried before using the covers.

In this Pine ground and on hard bottoms were mostly collected about two thousand pots of Strawberries, which seemed in excellent condition. Many fine large plants were in large pots; but a great proportion of the plants were in 40-sized pots or in very small 32's, and no doubt these would be used for the earliest forcing, as the buds would be soonest matured.—R. F.

(To be continued.)

most extensive of its kind, are justified by the number of entries, which already amount to two hundred.

WORK FOR THE WEEK.

KITCHEN GARDEN.

ALTHOUGH the utility of trenching the ground in kitchen gardens, and bringing up a portion of the subsoil to mix with the surface soil when the latter is said to be worn out with constant cropping, are generally admitted, there are some who are indifferent to its advantages. If the soil should be stiff loam, they are fearful of mixing a small portion of it with the surface soil, although the latter may be like an ash-heap and as rich as dung can make it. We are aware it requires some judgment as to the quantity of subsoil to be brought up, as the texture of the soil may be materially injured by a large quantity at one time; but it can rarely so happen with a small quantity, and as many old gardens would be greatly benefited by the operation, we trust it will receive attention at all favourable opportunities. *Artichokes*, immediate steps to be taken to protect the roots from frost. In some situations this may not be necessary, but it is best to be on the safe side. We have known a whole plantation destroyed by frost, in what was considered to be a very favourable situation, and where it was thought quite unnecessary to protect them. *Cabbages*, all that are sufficiently grown to admit of being earthed-up, should have it done before frost sets in. Red Cabbage for spring use may still be planted. Continue to encourage the planting of crops in every respect as previously directed. Plant out everything in the way of Cabbage or Colewort plants. The Carrots, Beet, &c., being taken up and stored, let the ground they occupied be trenched, and where the soil is of clay or strong loam, let it be ridged that the frost and air may act on as large a surface of it as possible. Ground may now be got ready for new plantations of Asparagus, Sea-kale, and Rhubarb, and as these are what may be termed permanent crops, every care ought to be bestowed on the thorough preparation of the soil for them. The depth to be from $2\frac{1}{2}$ to 3 feet, and thoroughly drained, trenched, manured and pulverised; and where the soil is comparatively exhausted in some of its essential qualities, as nearly all old garden soil is, there ought to be an addition of new loam—for real success in Asparagus-growing this is imperative. Clear away dead leaves from all growing crops, and fill up blanks in them. Take the opportunity of unfavourable weather for out-door operations, to tie-up mats, prepare label-sticks, store up roots, and see that a good supply of covering-materials is at hand when required.

FLOWER GARDEN.

Old-established shrubberies should now be gone over and pruned. We do not mean by pruning that the shrubs should undergo the wholesale denudation of branches and foliage we sometimes see when this operation is performed, but simply the shortening or removal of all dead and straggling branches, taking care to cut in such a manner that the foliage shall conceal the incision made in the branch. Tulip-growers must recollect that people now begin to plant their blooming bulbs. All offsets should be in the ground now, and the main beds had better not be delayed. The Dahlia-growers have been puzzled this season. In many places the plants are growing rapidly still. Their growth should be checked by the insertion of a spade or fork under the roots. Continue to examine Auriculas, taking off dead leaves, and, above all things, seeing that the plants are well dried and have no drip from the frames. Plant Anemones and Ranunculuses for early flowering; but the choice kinds are not put in till February. Plant Hyacinths and early Tulips, Narcissus, &c., in the open ground.

FRUIT GARDEN.

Continue to prepare for fruit-tree planting, by draining, trenching, and pulverising the soil, and after planting, stake, tie, and mulch them in good time. Clear away all dead leaves from the wall trees, and remove the green fruit from the Figs. The established strong-growing fruit trees that are tardy in producing fruit should be treated according to circumstances. If the trees are planted too deep, or the soil has been raised above or about them since planting, by

all means fork the roots out carefully and plant them again with care on the surface, spreading out the roots regularly, and then mulching them. If trees to be operated on are planted high and dry, fork about them at a reasonable distance, and prune back the main or strongest roots as you discover them. Raspberry plantations to be cleared of the dead canes and superfluous wood, the suckers to be taken off, and where required the strongest to be planted for succession.

GREENHOUSE AND CONSERVATORY.

Damp and mildew are the great enemies to be guarded against now, and these must be sharply looked after, especially in the case of plants that have not well ripened their growth, and are in a rather soft state. If damp is troublesome it must be dispelled by means of free ventilation on dry days, using a little fire heat at the same time, and for mildew a dry airy atmosphere is the best preventive; but the plants should be frequently examined, applying sulphur on the first appearance of the enemy. Very little water will be required here at present, but the plants should be frequently and carefully looked over, so as to make sure that no plant is allowed to feel the want of it. See that there are no broken panes of glass to cause drip, for the dark short days and natural humidity of the atmosphere at this season of the year are quite enough to contend with.

FORCING-PIT.

It will now be necessary to introduce into this structure a supply of those plants usually employed in early forcing; to begin with a gentle bottom heat and a moist state of the atmosphere, admitting a little air on every favourable opportunity. The following plants are available for the purpose:—*Pelargoniums*, *Scarlet Geraniums*, *Heliotropes*, *Aloysia citriodora*, *Alonsoa grandiflora*, *Camellias*, *Coronillas*, *Salvias*, *Cinerarias*, &c.; *Persian Lilacs*, *Sweet Briars*, hardy *Azaleas*, *Kalmias*, *Rhododendrons*, *Lily of the Valley*, *Pinks*, *Roses*, *Violets*, &c.; the bulbs of *Hyacinths*, *Tulips*, *Iris*, *Narcissus*, *Crocus*, &c., that have been potted and treated as advised some time ago. The whole to be managed so as to give a succession of bloom, which can only be effected by bringing into the forcing-pit a part of the stock at a time.

PITS AND FRAMES.

All stores intended to be wintered in these structures should be finally arranged as soon as possible. A dry atmosphere, with a considerable amount of ventilation day and night, are the requisites. An observant person may take a hint from the *Verbenas* which remain out in the borders. How often do we see these green through a great part of the winter. They are well-established, however, at the root, and would prefer a moderately dry frost to a murky and confined atmosphere. Everything that obstructs the light, or that has a tendency to generate decay, should be removed immediately.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

WEATHER windy and wet. Did little out of doors, except pulling a few weeds from gravel walks in the intervals of fair weather; cutting the edges and rough cleaning the sides of carriage road, by hoeing and raking when soft, and will rake again the first fine, dry, sunny day, to bring the weeds to the surface, or what is left of them, as at this season, without frequent scratching, hoeing and raking are of no avail. It is only the sides that need anything of this kind, as the centre is too hard and well used to permit of weeds growing. The ground is now getting wet, and we must look out for some stubble, if possible, to finish up our Celery before much frost comes. Made up slight hotbeds for Radishes, and Asparagus, but the ground must be a little drier before we can take up the latter. It is a great advantage for early work, when the plants are permanently planted in pigeon-holed pits, to be heated by dung-linings at the sides; but we have not got that length as yet. For Asparagus the pits should have glass sashes in winter, which would come in for other frames or pits in summer. For Sea-kale and Rhubarb, board covers would do. Where fermenting material cannot be had, hot-water pipes may run beneath the bed, and one pipe above to keep out frost.

We have grown very fine Asparagus in a dark place, by cutting the heads when 6 inches in length, and setting them in damp sand in a vessel exposed to light in the greenhouse, so as to take away the blanched appearance. We prefer, however, what is grown green; and when a part is taken up every year, though the waste is great, the Asparagus ground comes in for many crops in rotation. Sea-kale, and Rhubarb, too, may be grown in the dark as well as not, but neither should be allowed to elongate too much, or the heads and stalks become watery and lose firmness. Earthed-up our third piece of Mushroom-bed, using fresh stiffish loam, kneading and beating it firmly, and making it as smooth on the surface as a plastered wall, by wetting it and drawing a clean spade firmly over it. Put a slight covering of old hay over the shallow bed to prevent the heat escaping. The first piece is now yielding freely, and we gather still from the last piece in the open shed. We have often proved what the last season has also demonstrated, that almost any fermenting material will do for growing Mushrooms when not too wet nor too dry, and when not already permeated by the spawn of other fungi. We have used tree leaves and grass for the bottom of beds, but it is well to give them a good heat at first, as otherwise in raking the leaves you are apt to collect the spores of other fungi with them, which would be destroyed by a sharp heat. The first piece in the shed had been made chiefly with old stubble, brought from protecting Celery, &c., thrown into a heap and fermented, and cased with about 2 inches of dung and horse-droppings. Our first bed in the Mushroom-house was about two parts short litter, two parts horse-droppings, and one part rough dry turf, that had been in a heap for nine months, roughly chopped. On the whole, however, the richer and the less exhausted the materials the better the Mushrooms, and the longer will they bear. We find in our spawn-heap the thin cakes are spawned more quickly and regularly than the thicker bricks or cakes, and, therefore, we mean to make thin cakes in future—that is, say 9 inches in length, 4½ inches wide, and from 1 to 1½ inch in thickness. They are also fit for spawning in half the time.

We feel much obliged for the many kind hints we receive as to these "Doings." Fine clean Celery in winter is a matter of great moment in most families. Clearing away all suckers, tying the heads so as to keep soil out of the heart, and not smothering the heart, are some of the means for securing that object, in conjunction with ashes to keep away worms, and stubble and straw in stiff soils near the top. We have much pleasure, so far as blanching is concerned, in placing before our readers the plan adopted by our friend Mr. McDonald, of Woodstock Park, Ireland, feeling sure he will forgive the liberty we take in making public the following extract from his letter:—

"For several years I have been experimenting with various materials in blanching Celery without using earth. To grow a crop of clean, well-blanching Celery I have always found the most difficult and important work of the kitchen garden. It is a great disappointment, when the Celery is wanted for use, to find that not unfrequently the half of it is useless, or in such a state that it can only be presented in morsels. Of the various materials I have tried, moss has on the whole proved the most satisfactory. Last year it was applied to the early Celery when the plants were nearly full grown, and the results elicited praises alike from kitchen and parlour. This season old fern bracken has been used, which had been in stack for some time, and we have had charmingly clean white Celery of a size that would not disgrace a Manchester show-table. To earth-up Celery properly requires good skill and practice, as, if carelessly done, a large per-centage of the crop will be comparatively useless. Besides guarding against these drawbacks, the plans I have adopted, where moss and fern are plentiful, as they are here, become an important matter in garden economy, as one man will do more than six men in the ordinary way of earthing-up."

We are sure many readers will be obliged to Mr. McDonald for the above plans of blanching Celery—plans which in our estimation, however valuable for early crops, will even be more valuable still for winter and spring crops. Both plans will allow air and water to pass, and keep out light, and thus rotting will be prevented. We once saw bog-earth, such as that with which fuel-peats are made, used for a

similar purpose, the heap going across the garden as the Celery ground did. Many who cannot obtain moss or fern may hit on some other substance somewhat appropriate now when they know how useful such things are. The little moss we can obtain is generally so well supplied with slugs and snails that before using it for anything very particular we generally soak it in hot lime water. We presume, however, that St. Patrick banished all such vermin from Ireland. Certainly some of the finest flower-beds at Woodstock were carpeted with very green moss, and looked as if they had never been touched; whilst when we used such a covering, even for vases, we had the pleasure of seeing the moss all over the walks and lawn in the morning, though pretty well secured too; the birds doing it all before we got out of bed, either in search of slugs and worms, or out of sheer mischief. There are many places where quantities of fern can be had for the cutting. A keen frost will go but a little way into either moss or fern. Much good Celery well earthed-up is often ruined from the frost penetrating the earth. Green Celery will stand a good deal of frost; when blanched it is easily injured, and when the heart is gone the rest is pretty well useless.

FRUIT GARDEN.

Finished clearing Peach-house, watering the borders with hot water, &c., and laid Strawberry plants behind a north wall, and laid pots of others down to prevent excessive chrenching. Looked over Grapes and removed any damping berries, and kept a little fire and air on constantly in such showery weather. Protected the border of the late-house with old sashes and straw covers.

ORNAMENTAL GARDENING.

Nearly finished a small stove for the reception of plants, having altered the internal arrangements without altering the heating-pipes, &c. Pruned back the climbers in conservatory, washed all the glass inside and outside, stages, shelves, &c., and nearly finished fresh arranging the house with Azaleas, Camellias, Epacris, Geraniums, Cinerarias, Primulas, &c. The outside of the glass has chiefly been dulled since May, so as to resemble ground glass. Size water with a little turpentine and oil were used, with just about the size of a walnut of whiting in a gallon of the mixture. This was put on the glass rather hot quickly with a brush, and then dabbed neatly with a dry brush. We believe this would have stood several years, as it was firm when taken off, but we wanted more light in winter. Choosing one of these damp days the glass was rubbed with a wet cloth, and after a short time the mixture was washed off with another cloth, and water through the syringe or garden-engine. As we do not wish to damp the house unnecessarily, we prefer this kind of shading to be outside. No soap water was used or needed, as if at all strong it is sure to injure outside paint. Gave plenty of air to all sorts of plants in frames and beds by elevating the sashes back and front, but so as to keep the rains out. In some days and nights was obliged to keep all the lights close and wedge them too, the wind was so boisterous, and if an opening were given a whole roof might soon disappear. A little precaution in this way might save much broken glass. The flower garden with wind and wet is fast becoming a wreck. Some fine huge plants of Ricinus have been much broken. Last year they did not do much, but they and Camas succeeded well this season in small clumps, dug out a yard deep, and filled for 2 feet with hot fermenting material. There is no question that much could be done with bottom heat in the open air, but for the trouble and expense of applying it. Dahlias are still showy. Plants in rooms should now have no more water than they need. On the whole, a spare room with plenty of light is a better place for keeping bedding plants for small gardens than a cold pit or frame.—R. F.

COVENT GARDEN MARKET.—Nov. 7.

The supply both of fruit and vegetables is large. Hothouse Grapes and Pines are very plentiful; of Dutch Grapes also, large quantities have come in during the week. Of Potatoes there is a heavy supply, both coastwise and by rail. The kinds of Apples and Pears which are offered remain the same as in previous weeks. Cut flowers principally consist of Roses, Heaths, Camellias, Fuchsias, Scarlet Geraniums, Chrysanthemums in abund-

ance, Violets, Mignonette, Chinese Primulas, and a few Petunias and Pinks.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

CONSERVATORY-ROOF (A. B.).—We advise you to follow our own mode of proceeding. We write to two or three parties who advertise the kind of structure we require, describe it to them, and ask for an estimate.

AMMONIA IN HOTHOUSES (Amateur).—You will see on reference to page 326 and elsewhere, that your suggestion has been anticipated.

VINERY BOILER EMPTY IN WINTER (An Old Subscriber).—If the boiler and pipes are entirely emptied of water, neither they nor the Black Hambrogh Vines will sustain any injury however severe may be the winter. If water be left in the pipes some part of them might be burst by the water freezing.

DESTROYING RUSHES—VEGETABLE IVORY (M. C.).—Thoroughly draining the pasture will destroy the Rushes, they can only live in a wet soil. We know of no other mode of subduing them, except by constantly uprooting and cutting them down as soon as they appear. Vegetable Ivory is the seed of the *Phytolophus macrocarpa*, one of the Screw Pines. It is a native of Peru, and the nuts are imported in such quantities, that not long since one thousand were sold for 7s. 6d. There is an excellent account and two drawings of the plant in the "Botanical Magazine" for 1856. We should sow the seeds at once in sandy loam, covered an inch deep, and place in a stove.

PRIMULAS WITH SHORT FLOWER-STEMS (P. C.).—We fear you are allowing your Primulas to bloom too soon—that is, ere the plants are strong. It is a good practice to take the first bloom-buds off, as it strengthens the plants. You are, perhaps, keeping them too cool, and that will cause the stems to be so dwarf. Primulas require a warm greenhouse to flower in in winter, or a house with a temperature seldom lower than 45°. We think additional heat would cause the stems to lengthen.

SLUGS ON CALCEOLARIAS (Idem).—We never yet knew slugs eat soot, nor that they would come near it if they could do otherwise. Examine the plants at night with a lantern, and catch the depredators in the act, and lay some cabbage leaves in the frame at night, which are to be examined in the morning. The slugs will be found on the under side, and if they be swept off into a flower-pot with the hole corked and a little salt sprinkled upon them they will trouble you no more. The leaves will require changing and renewing occasionally.

PRUNING ROSES (A Subscriber, Warwick).—We do not consider autumn pruning a desirable method. February or the beginning of March we consider preferable. You may shorten the shoots to 6 inches in November, or you may prune them in the latter part of that month or beginning of December; but we have found such early pruning result in the death of many of the shoots, particularly when severe weather follows close upon the pruning. Tidiness, always desirable in flower gardens, should never be sought at the expense of the future wellbeing of the plant.

FLOWER-GARDEN PLANS (M. H.).—There are several in "Gardening for the Many."

HEATING A PIT (A Subscriber).—We are very sorry, but we do not think we can add anything more to that which we published at page 319 about your iron tank. We fail now to comprehend your description of the tank raised above the flue, with chambers beneath, &c. A section would have made all clear. We would have preferred the tank being set on the flue, not 3 inches above it, and we think you complicated the affair with your turf and sand above it, and all the rest of it. The simplest way you can manage the tank is to pour hot water into 3 inches at the bottom, have thin slate over that, and then sand or tan to plunge in, and then cover the top with moveable squares of glass. With such means you may strike any sort of cuttings. Why you failed we cannot clearly see, because we do not know the processes you adopted. For all the minutiae of cutting-making, and much besides, see "Window Gardening." By such a mode you may use your present cold greenhouse for the purpose, and your little propagating place will be much handier than any bed or pit out of doors. We have read over carefully your proposal to have a flue through a two-light frame with this iron tank at side and top, and a chamber for steam formed by a slate covering, &c., and the result in our opinion is, that when you heat by such a flue you had better make use of your tanks for something else, as holding clean or manure water, and depend on the flue alone for the heat you require. For instance: you want a good heat for propagating in two lights (it matters not whether frame or pit, though we should prefer the latter), and a more moderate heat in six lights. Well, it would be best to beat the first two lights separately by taking the flue round—say 2 feet or 18 inches from the sides, and shut off from the pit by means of a damper. Move the damper, and the heat would at once pass along the centre of the pit to a second chimney at the farther end, or, but for the expense, it could return and join the back flue in the two lights. With such a contrivance the cheapest plan would be to fill up all round the flue with brickbats, stones, flints, &c., so as to be as open as possible, cover the top of the flue and all across with pebbles, and then gravel and sand. The next best would be to make a chamber across with rough slabs of wood, leaving openings between them to be filled with clinkers, stones, &c., and sand or tan above. The next and more expensive mode would be to cover all across with flagstones, slate, or iron; and whichever mode was adopted, there could be no want of heat or moisture by any of the modes frequently alluded to. A pipe communicating with the stones round the flue would always give moist heat enough.

ERRATA.—Page 350, second col., seventh line from top, "heat was not wanted," leave out next. Next paragraph, "fruit wall," should be "front wall." Page 351, first col., seventh line from top, "warm borders" should be "side and end borders." Page 358, first col., sixteenth line from bottom, instead of "ten years," read "two years." To give the same amount of protection from two to three mats would be needed every year, and then the protection would not be equal.—R. F.

BOILERS (Subscriber).—Both your gardener and builder are, to a certain extent, right; but as far as the burning, if "anything," is concerned, we prefer the saddle to the tubular form, while for efficient heating and attention in stoking we very much prefer the tubular. At the same time the saddle is also a good boiler in these two latter respects. We would advise you to let your gardener have the saddle if he prefers it, and more particularly if the firing to be used is not of the best description. He will then be most likely to meet your wishes. If your house is for late Grapes—that is, autumn Grapes—and bedding plants in winter, a flow and return four-inch pipe will be enough.

THUNDERBIA (HEXACENTRIS) COCCINEA CULTURE (C. G.).—Keep your plant dry and cool through the winter, and when in spring it begins to grow freely, shift into rich turfy soil and grow on fully exposed to light, and if it does not flower under such circumstances, you may consider you have a shy-flowering plant not worth expending labour on for another year.

REMOVING YUCCAS (F. Newman).—The end of April is a good time for removing Yuccas. Take out a trench round them, and move them with as much soil to their roots as will adhere to them. Water well when planted, and shade from bright sun for a time. They are as easily and as successfully moved as a laurel. It will be best to pot the suckers of the Aloe singly into small pots.

SUPERPHOSPHATE OF LIME TO VINE-BORDERS—PINES PLANTED-OUT (F. H.).—You may apply the superphosphate of lime at the rate of 2½ bushels to a rod. The best time to apply it is when the Vines are starting. You should not start your two-year-old Vines, particularly if they are weak, till February. You will succeed very well with your Pines by putting 2 or 3 feet of firmly-trodden Oak or Beech leaves below the soil. They will yield heat more or less for twelve months. We do not like such a mixture as you describe for planting Pines in, and prefer moderately rough loam, with about an eight-inch potful of bone dust, to a barrowload of soil, and afterwards to water with liquid manure.

BORAGE (Nemo).—It is an annual. You would gain nothing by sowing before March. You may plant *Lilium lancifolium* now. The bulbs should not be disturbed oftener than once in four years.

MR. FORTUNE'S PLANTS (Daimio).—If you write to Mr. Standish, Nurseries, Ascot, he will give you the information you seek.

PLANTS FOR AN EASTERN BALCONY (S. F.).—We know of nothing better than masses of *Chrysanthemums*, or *Acubas*, *Laurustinus*, and *Cypresses* in tubs, with borders of *Snowdrops* and *Crocuses*, with a few *Hellebores*. Where is your balcony, in town or country?

ROSES AND CLEMATIS MONTANA NOT FLOWERING (Leighton B.).—If you had stated more particulars as to the soil and situation in which your Roses grow, and what sort of Roses they are, we would be more likely to hit on the cause of their not flowering. Roses when grown in shady situations, and not sufficiently thinned out with the pruning-knife do not flower freely nor produce fine flowers. When in a good exposure and kept properly thinned of wood Roses seldom fail in flowering if healthy. The same remarks are applicable to the Clematis, it being a remarkably free-flowering plant when grown in an open situation, and particularly on a wall. If they are thick of wood thin well out, and let sun and air to them, and if both Roses and Clematis are healthy they will flower. The planting of *Climanthus* had better be deferred till spring.

PLUMS AND CHERRIES FOR NORTH WALL (Mrs. Burrows, Caran).—Plums: Early Orleans, Drap d'Or, Reine Claude Violette. Cherries: Morello, May Duke. We cannot detect your plant from such a specimen. Send a sprig and some of the fallen flowers in a card-box and a little damp moss.

VINES IN POTS (A. Beal).—You cannot do better than keep your Vines in your cold greenhouse all winter, if the temperature does not exceed 40° with fire heat. They will do under the stage in any cool corner of the house. As soon as ever they show signs of swelling their buds in spring train them up under the rafters of your greenhouse, keeping them at least 16 inches from the glass. The pots on stand on the front shelf with which your house is, no doubt, furnished. The sorts are not well adapted for fruiting in a cold greenhouse. Few Vines require so much heat as *Alcane*, and both *Lady Downes* and *Black Muscat* require more heat than *Hamburghs*. If you could exchange them with any one for *Hamburghs* the latter would be more satisfactory in a cool house. Of course, if you can keep your greenhouse warm from May till September they will do very well.

ALTERING THE TIME OF FLOWERING IN CAMELLIAS (South Devon).—The time that *Camellias* flower depends so entirely on the time that they make their young wood and set their buds, that you must let this process take place later in the season than has been the case with yours. To gain your object as quickly as possible, keep your plants as cool as possible all winter and early spring; and, instead of putting them in heat to make their growth and set their buds, keep them in a cool, dry, and somewhat shaded position. This followed out for a year or two will cause your plants to be later in making their growth and setting flower-buds, and as a consequence they will flower later.

TREDIZONO NUT TREE (Leamington).—This is mentioned in the "Gardeners' Year Book for 1863," and our correspondent wishes to know where a plant of it can be purchased.

PATENT STOVES (H. C.).—No such stoves, for they have no chimneys, should be admitted among plants. These are always injured by the fumes from the fuel.

MAKING ASPARAGUS-BEDS—PLANTING SEA-KALE (H. Howell).—The ground should be well drained to the depth of 4 feet, and 21 feet from drain to drain. The ground should then be trenched to the depth of 3 feet, and 6 inches of manure worked in. If the soil be deficient in sand or clay a like quantity of sharp sand or ashes should be added to it and worked in. Divide the ground into beds 5 feet wide, pointing north and south, with two-foot alleys between the beds, and driving a stake down at each corner of the beds. Cover the latter with a layer of well-decomposed dung 3 inches thick, and throw out the alleys equally over the beds to the depth of 1 foot. Fork the beds over and leave them rather rough for the winter. The beds should be prepared this month, taking advantage of dry weather. You will plant three rows of two-year-old plants along the beds, the outer rows 1 foot from the edge of the beds, and the same distance from plant to plant in the rows. We consider *Giant* or *Early Battersea* the best variety to plant. Prepare the ground for the Sea-kale in the same way as for Asparagus, but do not form the ground into beds. Plant in lines 2 feet 6 inches apart, running north and south; three plants together, 1 foot 3 inches asunder in the line, so that they will represent the points of an equilateral triangle thus, " " and 6 inches from crown to crown. (E. A. F.).—See the above reply to H. Howell as to how to make the beds. We do not recommend planting full-grown plants, as they rarely do any good. Two-year-old plants, and even one-year plants from the seed are better. They should be planted in the beginning of April. Four years is about the time necessary to obtain Asparagus fit for cutting. If the grass be strong, at three years a few heads may be cut; but the strength and time of coming into bearing depends on the liberality of the treatment given, as liquid manure twice weekly in summer.

THE USE OF DAMPERS (A Constant Subscriber).—A little grumbling now and then is vastly superior to continual flattery. We do not like dampers because they confine the smoke and its direful gases in the flue, whilst exposing the fire to a full current of cold air. This confining of the smoke materially aids in bursting flues from the collection of gases in them, which, becoming ignited, explode, because the damper prevents their escape by the chimney. Confining smoke in a flue by means of a damper is just the same as working a steam boiler to the highest pressure its parts are capable of resisting and then shutting the safety valve. If you stop a racehorse at full speed the collision is fiercer than when the animal is walking. So with dampers. The damper checks the draught, but not until the air has attained its full velocity; and do you think that it is not better to prevent the draught by shutting the ash-pit door than to allow it to rush in there, and then by means of a damper to hinder its passing along the flue? Dampers fill flues with smoke, prevent its free passage to the chimney, and if there are any cracks in the flue the smoke thus confined is sure to find them out. Dampers cause an unnecessary strain on all the parts, and this sooner or later ends in a smoky flue. Dampers fill flues with soot, and are always out of repair. If no air can reach the fire—under, through, or over it at the furnace—the fire cannot burn at all. The draught is given at the furnace, and where the cause begins that is the place, and that only, to check or increase it. The furnace-door should be as air-tight as it is possible to make it, for we want no air to enter there to cool the air that rises from the fire; but the admission of the air that gives the draught should be by the ash-pit door, so that the air will pass through the fire and become heated before it passes into the flue. Providing the ash-pit door fits closely and the furnace-door the same, the fire will burn very slowly indeed in a wind; and if they fit quite closely, admitting no air, a strong fire will gradually die out. Let us examine any of the slow-combustion stoves used for warming halls, and what principle are they on? The ash-pit door regulates the draught; the stove is made hotter or colder by shutting or opening it, and not by having a damper to hold back the heated air and fill the room or place with gases and smoke. The parts above the fire should be open at all times to afford a free passage for the smoke to escape by, and the opening below the fire admitting the air can be regulated at will by shutting or opening. We have no difficulty in regulating the draught of our fires, and we never have used a damper; but we have had to work many flues and boilers where they were, yet never did, and never will, use them. We have worked flues that burn a ton of coals per week individually, without any ash-pit door or even a damper, and could have any heat of flue by raking the fire according to the weather. If your ash-pit door is made to fit quite close, and does not then prevent that roasting heat you complain of, we can only say your furnace is too large for its work, and must burn fuel that would be economised by having a less furnace.—G. A.

AIR PIPE (G. Child).—We have it inside the house. No steam ought to escape from it.

GLASS (A. Q.).—It will do very well for your "groundinery." We have no information relative to ripening Peaches in such a structure.

LIME GROUND FOR RHODODENDRONS (M. H.).—Lime will not be detrimental to Rhododendrons after having been incorporated with the soil for two years. We would advise you to defer planting the Potatoes until spring, which would allow of the surface being left rough and the frost pulverising it. The lime could then be applied in March, when the ground would not be so wet as now. Four tons are a good dressing for an acre of land.

PLANTING CLIMBERS (G. H. P.).—We should keep the climbers in pots until spring, and then plant them out in the boxes specially provided for them.

KEEPING DOWN THE HEAT IN A VINERY (A Tyro).—Your pipes may be covered with boards as you propose, and then covered with hair-felted such as is used for covering steam boilers. If you were to have both ends of the trench open so that the heat could pass out, it would not become so hot as if confined exclusively within the trench. By abundant ventilation you may keep your Vines cool, and they will be none the worse by not being frozen.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (H. B.).—1 looks like a *Microlepia*, but too young to name; 2, *Pteris hastata*; 3, *Lastrea filix-mas*; 4, *L. dilatata*. (*Six Years' Subscriber*).—We cannot name Comfers usually from merely leaved scraps.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

CREVE CŒURS.

We redeem a promise made some time since to one of our correspondents, who asked for some information respecting Crève Cœurs, stating he thought such would be of general interest. We are indebted to the excellent French work of M. Jacque for much of our knowledge concerning this breed, the rest being the result of some years' observation and breeding.

The Crève Cœur should be black entirely, but it is difficult to obtain such. In common with all other black fowls, they have a tendency to become particoloured. The cocks get red, yellow, sometimes white, feathers in the topknot, hackle, and saddle, more frequently the two latter. The hens show them principally in the topknot, and they increase with age. A remarkable feature in the Crève Cœur cock is the singular comb, composed of two spirals or spikes, sticking up in front and looking like horns. They are sometimes smooth and wide apart at the ends, sometimes close together, and sometimes very wide apart, throwing out small branches like the horns of a young stag. Add to this, that he has an ample topknot falling backwards, with the exception of a few straggling feathers that come forward, that he is plentifully whiskered, has an ample beard hanging below his wattles, a bright eye, an intelligent face, and a grave look, and you have a truthful description of this singular head. The body is very symmetrical, being deep, square, and well seated on the legs, which are short. It gives the appearance of being what it is, a good table fowl. It is four-clawed, and has blue legs. A cock, being a good specimen of the breed, weighs from 6 lbs. to 7 lbs. The hen has a larger topknot than the cock; it is also rounder, she has very small wattles, but she has a large beard and thick ample whiskers. She also has a square body, and short dark blue or black legs. Weight from 5 lbs. to 6 lbs. There is a latitude allowed by the best French judges in the topknot of these hens, which would not be admitted in Poland in this country. We will on this point quote verbatim from M. Jacque.

Speaking of hens he says:—"The topknot is of variable dimensions, sometimes composed of short feathers falling and turning little over, leaving the eyes plainly visible, sometimes forming such an abundant head-dress that it conceals the head itself almost entirely, and the eyes are of use only to see that which is on the ground. Very small wattles, and small whitish deaf-ears. Good average layers of very large eggs, and non-sitters."

Our own experience enables us to add, that we consider them far more than average layers. We have found them lay as many eggs as the best of our laying breeds, in many instances more, and they have the advantage that their eggs are quite as large or larger than Spanish, with plentiful yolks and most delicate flavour. We have found them easy to rear. We will conclude with another quotation from M. Jacque.

"This admirable race certainly produces the most excellent fowls that appear in the French markets. Their bones are very light; their flesh fine, short, and fattening easily. Their chickens are of unheard-of precocity, since they can

be put up to fatten at from ten to twelve weeks old, and be eaten a fortnight afterwards. At five months old a fowl of this breed has nearly attained its growth, weight, and quality. At six months, being well fattened, it should weigh 7 lbs., and sometimes attains 9 lbs. The Crève Cœur breed supplies the poulardes and choice chickens sold in the Paris market. It is the first breed in France for delicacy of flesh, for facility of fattening, and precocity. I think in these particulars it is the first in the world."

TONBRIDGE WELLS POULTRY SHOW.

Coming closely on the heels of our correspondent's lamentation that no shows existed in the south or south-east, is the announcement that one took place at Tonbridge Wells on the 23rd of October, in connection with the agricultural meeting held in that town.

As a first attempt it must be considered eminently successful, so far as entries, quality of birds, and attendance were concerned. If it is to be annual, it will be well to make it imperative on all exhibitors to provide proper and convenient baskets for the purpose. They are inexpensive, and always useful in a poultry-yard. When such are used, all that is required of the Committee is to erect stands on which they are placed. Uniformity is gained, and the birds are shown to advantage; while if the pen or cage be left to the option of the owner, it is astonishing what strange devices some of them adopt, from a piano-case, or china-crate, down to a blackbird's cage. Many such were ranged in a spacious tent on the beautiful spot selected for the Show. It was large, but would not contain all. The weather was fortunately all that could be desired, and the pens were ranged out of cover.

Kent is famed of old for *Dorkings*, and maintained her reputation on this occasion. The first prize was taken by Mr. Dolby, who, we believe, has only lately become a Kentish man; second and third by the Rev. Mr. Barnes, who showed excellent birds. Those belonging to the Earl of Abergavenny were also very good. The next class in merit was the *Game*. Mr. Hughes, and Lord Abergavenny, deserved their prizes. *Turkeys* were excellent. So were the *Geese*. There were some cross-bred between Toulouse and common, that were most meritorious. The same may be said of *Ducks*, which were well shown, both in classes and as varieties. Mr. Dolby's success was completed by taking the prize for the best collection. He is too good an exhibitor for a young show. He took first for Dorking; first for Silver-pencilled Hamburgs; second for *Turkeys*; first for *Geese*; first for Aylesbury Ducks; first for various Ducks. Lord Abergavenny took the second prize for collections. In *Hamburgs*, *Polish*, and *Spanish*, the quality of the birds shown left much to desire.

Mr. Bailly was the Judge.

NORTHERN COUNTIES POULTRY SHOW.—The entries for the eleventh annual Exhibition of Poultry at Darlington close on Monday, the 16th inst. The schedule of prizes comprises classes for adults in Black Spanish, Coloured Dorkings, White Dorkings, Buff Cochins, Any other variety of Cochins, Brahma Pootras, Black and other Red Game, Any other variety (Game), Gold and Silver-pencilled and Gold and Silver-spangled Hamburgs, and Polands; while in Bantams classes are allotted to Gold or Silver-laced, Black or White, and Game. The Ducks are Aylesbury, Rouen, and Any other variety. *Geese* and *Turkeys* have also classes, as well as Any other distinct breed of poultry; and a Selling Class is introduced, the price per pen not to exceed 30s. The prizes range from £3 to £1. Pigeons are divided into thirteen lots. In addition to the above, all the principal varieties of poultry have distinct classes for birds of 1863, as well as for pairs of pullets, and in some cases for single cockerels. In several varieties, also, single cocks of any age are included. To add to the interest of the Exhibition, no less than fourteen silver cups, principally presented by friends of the Society, are offered for competition, varying in value from £3 to £5—the winner to have the option of taking the cup or the amount in money. In classes where cups are awarded the first prize will be with-

held; but unless three pens compete in any class the cup or first prize will not be given. Instead of the usual shed, so unweatherproof as it has long proved, the entire collection of feather will be arranged under the new covered market, which, how much soever it may be condemned as blocking up so fine an area for the healthy circulation of air in the heart of the town of Darlington, is yet an admirable accommodation for the Northern Counties Poultry Society.

SELLING POULTRY.

WILL you tell me what is the usual rule in selling poultry? I have often seen it urged in your Journal that one should not send fowls without being paid beforehand; but in several cases when I have asked for a post-office order to be sent before sending off my fowls it has seemed to give great offence, and in some cases has stopped the sale altogether. What ought I to do in dealing with strangers?—L. S. D.

[In dealing with strangers we invariably ask for a reference or for prepayment; and no one who admits the dictates of common sense would object to give either the one or the other. We always say in reply to an intending purchaser if unknown to us, "You will not misunderstand us when we say that we shall be obliged by a reference or, if you prefer it, prepayment; the money to be returned, deducting any expense, if the fowls are not satisfactory." Of course there are purchasers of too-well-known character to require such a precaution.—Eds. J. or H.]

PENS AT THE BIRMINGHAM POULTRY SHOW.

THE very important article in your last Number, in reference to the above subject, is a matter of too much importance to pass unnoticed.

Your correspondent, "OLD COCHIN," asks if it is the intention of the managers of the forthcoming Show to enlarge the pens. The frequent complaints that have been made through the medium of your Journal, and the silence of the managers of the Show in reference to this very important alteration, lead me to conclude that no alterations will be made.

It does indeed appear singularly strange to pooh-pooh at the poultry part of this great Exhibition. No expense is spared in any improvements which can be suggested in the cattle department; and if the trifling expense in enlarging the poultry pens is so economically considered, I would suggest that a subscription be at once raised amongst the exhibitors of poultry to defray the expenses, and that the alterations be at once made. Your correspondent, "OLD COCHIN"—and, being one of that breed myself, I can endorse the truth of his complaints—states only the injury it is to the birds. That is bad enough, it is true; but a greater evil than that exists—that is, the awarding of the prizes. Some very great errors have been made of late years, and particularly in the larger varieties of fowls. I for one most willingly exonerate the Judges, for in some of the pens containing three Cochins if the cock bird should be at the front of the pen, no sight whatever could be gained of the hens, and, doubtless, the Judges at the time have thought it a Single Cock class, and awarded the prize according to his merits only; hence the blunders that have been made in some of the classes. I am quite sure enough has been said upon this important subject; and if exhibitors find upon entering the Show this year that the same evil still exists, I would advise those who possess the large breeds of birds to keep them from Bingley Hall in future, and send them to any other Show in England, and they will find better accommodation for their birds.—A BIG COCHIN.*

STATING THE AGE OF POULTRY EXHIBITED.

I THINK that you would be doing a service to exhibitors of poultry if you would recommend in your pages that the framers of rules should require nothing respecting age, except that chickens should be the produce of the current year. To compel persons to state, a month before a show,

* We have just received information that the pens for Ceechin-Chinas and Dorkings will be increased in size.—Eds.

exactly the number of months which their birds have been hatched is to ask men to do what they cannot do with accuracy where a large number of birds are reared. Everybody is liable to accident; and if when the schedules are filled up you intend to exhibit cockerel No. 1 and state his age as nearly as you can, it often happens that cockerel No. 2 has to be sent in his place when the show really comes, and this bird is probably of a different brood and a different age to the former. Here is a fertile source of incorrect ages. All that is really necessary is to insure that birds, exhibited in the chicken classes of 1863, have been hatched in 1863, and whether they are seven, or nine, or five months old is of small importance. Every fancier knows, I think, his chickens from his old birds; but, as the season advances, we forget to which brood such and such birds belonged, and, without intending fraud, make misstatements of the exact age of specimens. Besides, the schedules are sent a month before the birds go to a show, and between the times much may occur not only to change original intentions, but also to make us forget the age actually given. We are not all so careful as to keep a copy of the entry.

I trouble you with this letter, because inadvertently I have just exhibited a pen in which the cockerel was at least six weeks older than the pullets, and one age, I see by the printed catalogue, is given for all.

When the form was filled up and sent away, a very promising cockerel of the same brood as the pullets seemed to be the most suitable partner for them. When the day came to despatch the pen he was amiss, and another was substituted. I did not remember what age had been given, and till I read the catalogue a week after the show, I did not know any false statement had been made. Judges know quite enough to make an exact statement of the age unnecessary, and the public are misled and exhibitors embarrassed by attempting too much.—A BLUNDERER.

FORCED SWARMS AND ABORTIVE BROOD.

I FEAR Mr. Lowe must have thrown aside the remarks on which he has afterwards commented, after "a mere cursory glance" only, as he formerly threw aside the opinions of various authors on bee diseases. Doubtless, every one has a right to read or not, as he chooses; but we may reasonably expect that the non-readers will not be our critics. Among several other misquotations, Mr. Lowe puts between inverted commas, "there should be no failures"—speaking of forced swarms. The nearest approach to this occurs in my remarks at page 120, where I say, "There ought to be no such failures," plainly referring to a certain class of failures named in the context. Omitting the word "such" changes the meaning of the whole sentence. It would, indeed, be absurd, under any system of management, to say there should be no failures whatever. Are there not in the land of the mountain and flood some failures of natural swarms, from various causes, at various ages? "Be candid for once." There are a few such in England occasionally, perhaps as many in proportion as there are of forced swarms, when the latter are judiciously made; and who in the name of common sense ever thinks of driving them, "ready, or not ready?" When the honey season has fairly set in, when the population is overflowing, and drones have been reared, they are always ready. A natural swarm is a beautiful and a pleasing sight; but many bee-keepers cannot afford to indulge in the "mystical," or "poetical," at the expense of half their honey harvest, and of valuable time spent in watching and waiting; nor to share with their more affluent compeers a contempt for "mere commonplace considerations of profit and pelf." Is he who prefers natural swarms, even when they lessen his profits, is he really "the true apianian?"

Mr. Lowe charges us not to repeat that bees will carry out of their hives chilled and abortive brood. Nevertheless, I must and do repeat it. I will give an instance, not the only one I could bring forward, but I select it because a whole hive of chilled brood is an extreme case—one in which foul brood ought to have resulted, if such a result was at all usual. I had placed four forced swarms (made about the middle of June this year) apart from my other bees, in a

wooden house, not originally meant for a bee-house. This place is painted black, is almost air-tight, and when opened on a hot day feels like an oven. I was in the habit of leaving the door open on all sunny days, but going from home unexpectedly on the morning of July 10th, I unfortunately forgot to do so. The hives were full and heavy, though only three weeks old, the day was intensely hot, and when I returned in the evening I found that two heavy combs in the best of the four had collapsed, drowning a good many bees, and covering the floor with honey. Next morning I observed that the bees, in despair of putting things right, were joining themselves to the colonies on each side of them, and at night I took away their deserted tenement. Being much occupied with other matters, I could not attend to it further till the 14th, three days after its former occupants had left. I then took away the collapsed combs, put a couple of empty ones in their places, inserted a spare royal cell, already sealed over, and set it in a place till then occupied by two other stocks, removing the latter to some little distance. The returning bees entered, licked up the spilled honey, and applied themselves to raise a queen. I examined it frequently afterwards, and from the entire absence of young bees in the population given to it, I can positively say that the most advanced of its brood came to maturity, as did also the eggs. The rest, by far the greater part, perished, and were carried out by the bees, very gradually. Some remained in the cells till shrivelled up to a mere skin, but were ultimately removed when the colony got stronger.—JOHN P. EDWARDS, *Shirleywich, near Stafford.*

AN EXPERIMENTAL APIARY.

My design in writing the article titled as above was for good, to condemn all ill-timed and wrong-directed artificial processes and malpractices of whatever kind, and by whomsoever committed. I did not, therefore, anticipate such a wrathful outburst as has fallen upon it from Exeter, inasmuch as my subject matter was so discursive and general in its character. In any reference which I did make to Mr. Woodbury's writings, I have not knowingly or otherwise misrepresented or misquoted his views upon any subject, and I repel any such ungenerous insinuations.

I am reminded by Mr. Woodbury, however, that I have committed two errors. The first in reference to my having on a former occasion attributed to him the following expression, which is so trifling, as but for the remarks made upon it I should not have thought it necessary to notice it. I inadvertently said, "what *he calls* (for what *is called*) the great centre of bee knowledge." The other is with reference to the length of time Dzierzon recommends that a foul-brood-infected hive should remain unoccupied. I am reminded that he recommends an exposure to the sun and air for two years, and not *four*, as stated by me. I made no quotation, and simply wrote in this case from memory; but I need not say that I had no intention or motive to misstate matters, for the absurdity of recommending a cleansed empty hive to remain for two whole years exposed to sun and air before being re-occupied, would give as much point to the question parenthetically put by me, as if altered thus—"Would not one year and a half do?" The absurdity of the proposed period of two years could, I think, scarcely be increased by any extension of time.

Let me ask who amongst us would adopt such a recommendation? far less what Dzierzon calls the best course, "to destroy immediately by means of sulphur every stock in which foul brood is found to exist," or another opinion indorsed by Mr. Woodbury at page 97, "that except under very special circumstances it is unadvisable to attempt the cure of a foul-breeding stock; better far to consign its inhabitants to the brimstone-pit, the hive itself if a straw one to the flames, the comb to the melting-pot, and appropriate the honey to any purpose except that of feeding bees." Let those that have a mind take this advice, I for one should not do so.

In regard to the comb introduced by Mr. Woodbury into his hive containing a "mass of chilled and abortive brood in all stages," with such results I make no comment further than to say that every one has the means of testing both the desirability and effect of such a proceeding; but in

order that no erroneous conclusion may be drawn from the results, I should recommend old comb to be used instead of new.—J. LOWE.

[Absence from home prevented Mr. Lowe sending the above until just too late for our last Tuesday's Journal. We think that these pen-encounters may now cease. Mr. Lowe, we are sure, did not intend to ridicule any bee-keeper who in the true spirit of a searcher after truth, "asks questions of Nature," and accepts her answers. Mr. Lowe's design, as he says above, was "for good," and not to hurt any man's feelings. He certainly did express himself in a way that admits of painful interpretation, though we believe unintentionally. Here let the controversy close, and let all the belligerents read as an epilogue the following note from a clergyman and fellow apiarian:—

"Hold hard, gentlemen! No stinging, please. Pray, Mr. Editor, blow a few puffs of smoke into Devonshire and Edinburgh, if you have a pipe or calumet long enough, and make those sharp sounds we all in our avocations dislike to listen to subside into that lovely buzz of harmony, so pleasant to the ear of every bee-keeper when engaged in the union of those whose welfare thereby they seek to promote. What will become of us if we all get together by the ears? Permit me in all kindness to say, 'Do not smite so hard, brother Edinburgh.' 'Do not heed a rap or two on your sides, brother Devon; you are not obligated to go (like those bees of mine you taught me to drive the other day) whithersoever the rapper listeth.'

"Mr. Editor, gentlemen, readers, and all whom it may concern, excuse a short paraphrase on the speech of a well-known peacemaker, the Host of Windsor, and whilst I utter it I feel I shall have many to join in the hum. 'Shall we lose our doctor, our learned teacher? Shall we lose our clerk, our practical writer? Forbid it Heaven. Hold out thine hand, celestial; hold out thine hand, terrestrial. Boys of art, mayhap you both are right, mayhap you both are wrong; but I can deceive neither of you if I prevail to let peace be the issue. Follow me, lads of peace. 'Tis my vocation to lead, not drive, although I am—A HAMPSHIRE BEE-KEEPER.'"]

FOUL BROOD.

THE attention of bee-keepers has been of late led in a novel direction, and a new kind of infection in a hive, as it would seem to be, is exercising the ingenious speculations of some of your correspondents in relation to it—not always, I am sorry to observe, conducted in the spirit befitting differing doctors. Marvellous does it seem that practical men and authors, such as De Gelien, Payne, Bevan, Taylor, Golding, and others, of half a century's experience, and even upwards I believe, should be ignorant or totally silent respecting a contagious malady now creating a mighty sensation in the apian community. I trust the outpourings of wrath will descend lightly on my head if I venture to inquire whether any part of the evil can possibly be traced to the exotic bees of late years introduced into our apiaries. I give no opinion, knowing only what I read in your columns; but a communication in your last Number, from the pen of Mr. George Fox, opened to my mind a question, How far the altered and diseased state of his hive can be traced to the introduction of a Ligurian queen in the last spring, as detailed by him. Her majesty's fertile powers, and, as I think, the previous health of the hive, are demonstrated by the fact of her filling "eight combs with brood in a short space of time." Subsequently it was discovered that each comb was one mass of foul brood."

I should be sorry to cast any stigma on royalty; but my limited continental experience suggests the wish, that some better-informed correspondent would direct his attention to the inquiry whether the disease (in Germany for instance) has prevailed most in the native or among the Ligurian bees, of late years so largely imported there. Also, how far it is prevalent in their own alpine and Italian localities, and what may have been the effect of changed climate, or of hybridous operation.

I have somewhere read that a very fertile queen will occasionally be met with carelessly depositing her eggs in the cells, so that the larvæ are turned bottom upwards, and thus perish and putrefy, unable to extricate themselves.

Foul must be a hive thus circumstanced. Has microscopic observation, in any of the recent instances of putrid brood, been resorted to?—INQUIRER.

LIGURIAN BEES IN EDINBURGH.

In giving my experience of the Ligurians, it will be necessary to begin at the beginning. I received a Ligurian stock from "A DEVONSHIRE BEE-KEEPER" at the end of April, 1862. The hive arrived all safe, without the loss of a single bee. It appeared to be in a sound healthy state, but by no means strong. The bees commenced operations immediately on being released, but showed an inclination to quarrel among themselves. Next day there was a good deal of fighting, and there was no difficulty in being convinced that this was a domestic quarrel, because strangers could have been easily recognised. I have never been able to account for this singular conduct; but in a few days they appeared to have settled their differences and set steadily to work, but without much appearance of progress till about the end of May, when they began to increase so rapidly that, from being apparently the weakest, they soon became evidently the strongest in an apiary consisting of eight or nine other hives of ordinary bees.

In the beginning of June they threw a fine swarm, and, after the usual interregnum, another. Under ordinary circumstances this is considered the maximum number of swarms in this quarter; but the summer of 1862 was so backward and unfavourable that there was only one swarm of black bees from my apiary during the whole season. I was, therefore, very well pleased with what the Ligurians had done, and was much surprised, a few weeks after the advent of the second swarm, on being told a swarm of bees, supposed to be mine, had been found in a neighbour's orchard. On examining I found them to be Ligurians, which fully established my ownership to them. They were evidently a third swarm from my stock, which had left the hive unobserved. They had established themselves in the forked branch of a Pear tree and had constructed two large combs, which were ingeniously fastened to the under side of the branch. No time was lost in securing them; but so effectually had they secured the combs to the branch, using several of the surrounding leaves as stays, by attaching and working them into the edges of the combs, that they could not be kept entire. The bees were put into an empty hive, and the combs were found on examination to contain both honey and eggs.

After such a successful commencement with my Ligurian stock, I was chagrined to find, a few weeks afterwards, that all the young queens had turned out hybrids. I was not then aware of the risk of hybridising. There were eight or nine stocks of ordinary bees close beside them, and to this I attributed the evident deterioration of the young bees. The first swarm with the old queen appeared to keep quite right, the young bees being as well marked apparently as the old. I will, therefore, confine myself to its history.

Early in the spring of the present year, on looking over my stocks I found the hive in question very weak and requiring some feeding. It improved rapidly after March, and by the middle of April a distinctly audible hum was heard from it at a few yards distance. They occupied a Taylor's hive of eight bars: it is larger than the ordinary straw hive.

On the 15th of May, the day being cold and showery, they swarmed but never settled, and went back to the hive after a short time, but I fear lost their queen in the attempt.

On Saturday, the 23rd of May, they swarmed again, this time successfully, the day being more propitious; and the swarm, a fine one, was secured.

On Wednesday, the 27th of May, the second swarm made an unsuccessful attempt.

On Thursday, the 28th, they tried again successfully. It was a fair swarm.

On Saturday, the 30th, a third good swarm issued, and was secured; but they had settled in a hedge and could not be got into the hive easily, and were not, therefore, moved to their permanent position till the evening. A dead queen was found on the floor-board when putting them in position in the evening; and, as there had been some difficulty in

hiving, I was afraid the queen had been crushed, although the state of the bees in a compact cluster did not indicate this, and subsequent inquiries showed there had been two queens.

On Sunday, the 31st of May, the fourth and last small swarm issued, and was secured. Next morning two dead queens were found before the hive, showing they had finished swarming.

Here, then, were four swarms from one hive within eight days, and before the end of May—a result quite unprecedented in this quarter. These have all done well considering the season. Two of them I sent in August, along with a number of other hives, to the moors. The weather was very unfavourable during the greater part of the time. On returning I took a super from each, the one weighing 10 lbs., the other 11 lbs.; the hives weighing, without the supers, fully 40 lbs. Some strong hives of black bees have done as well as this, or nearly; but the greater number have not done nearly so well. With results like these I cannot hesitate to maintain the superiority of Ligurians over ordinary bees. I regret, however, to find that they are all deteriorated in colour and marking, including the first swarm, which should have contained the old queen; and this confirms my impression that the old queen was lost in the first attempt to swarm. I took every precaution this season to separate them from the black bees. I removed all my own in May to a distance of several miles, and the nearest hives were nearly a mile distant; but, notwithstanding all these precautions, they appear to have been hybridised. The young bees are not so light in colour and have the yellow bands less distinctly marked than the old. Whether they will lose the prolific and industrial qualifications which have distinguished them this season remains to be seen.—J. B.

"B. & W.'s APIARY, 1833.

(Continued from page 444, Vol. IV.)

Your apian readers may like to know how it has fared with my bees since I last wrote, both as regards the honey harvest, and my endeavour to Italianise my apiary. I will observe, first of all, that I have no further evidence to prove that any of my drone-breeding queens have been of the least use whatsoever. Again and again have the bees reared artificial queens out of Italian brood, but although there were plenty of drones, the offspring of these drone-breeders, the young queens, turned out drone-breeders one after the other to my great disappointment. Your readers already know how completely baffled I was all the early part of the year, my various hives being one and all greatly weakened of course, as I made each in turn supply a population to rear my artificial queens.

If your readers will turn to page 444, they will see that I had then three young well-marked Italian queens, sisters of the same age, at the head of three of my stocks. I am happy to say that two of them have done well, that which led off the virgin swarm from A and was hived in G, and that which I gave to F. Both these young queens have raised a family, amongst which are many well-marked Italians, especially the queen of F, which has proved a very prolific mother. But the queen of A somehow or other came to grief. I saw her in the hive two or three days after the swarm left, but she was probably defective, or else she never returned home safely from her matrimonial flight.

On the 25th of June, therefore, finding neither queen nor brood in this hive, which was evidently dwindling away, I drove the bees all out, and subsequently returned their box to them with four combs in it full of brood (worker and drone), taken out of my Italian stock C. The same day I also drove B, destroying its young English queen, and gave them C's box with the remainder of the Italian brood. The Italian queen of C and her subjects, thus turned out of their home for the third or fourth time, were put in possession of B, with all its treasure of honey and English brood. Surely now, thought I, my perseverance will be rewarded at last. It was now, and continued for many weeks, magnificent weather in the very prime of the season; yet no, again was I disappointed. True I saw two young queens perambulating the combs in A on the 7th of July, and

on the 11th a beautiful young queen in B, but nothing came of them. Italian drones were seen playing in and out of both hives on the 21st and 22nd of August, a sure sign that matters were unprosperous with them. Determined not to be beaten, I once more, August 24th, repeated the operation before detailed, by which the Italian queen and bees of C were driven out of their hive, and deprived of all their brood, another box full of honey and English brood being given to them. As before, the Italian brood was divided between A and B. At first I doubted if anything would come of it, for it was not till the 29th that the bees of A attempted to repair their loss; on that day, however, I saw a royal cell founded, out of which issued a young queen (not very well marked) on the 7th of September. And on the 12th of October, but not till then, I had the pleasure of seeing drone-killing going on vigorously in A, while a few pollen-laden bees were seen to enter it, and a good many in B also, these being the only pollen-gathering hives in my apiary. I venture to hope, therefore, that so far all is well, and that I have at length succeeded in rearing four pure Italian queens, and establishing them at the head of so many promising colonies. I need not detail the other operations of the season, which could hardly interest your readers. I will only revise my hive list, which now stands as follows:—

A. Pure Italian queen, sister to B's queen. Born in Sept., 1863.	B. Pure Italian queen, sister to A's queen. Born in Sept., 1863.	C. Pure Italian queen. Born in 1862. Sent me by Mr. Woodbury.
D. Hybrid Italian queen. Born 1861.	E. English queen. Born 1863.	F. Pure Italian queen, sister to G's queen. Born June, 1863.
G. Pure Italian queen, sister to F's queen. Born June, 1863.	H. English queen. Born 1863. (In garden.)	I. English queen. (Straw hive.) Born 1861. (In garden.)

All these hives are more or less strong in bees; two or three of them must be fed shortly or in spring, the rest are heavy.

And now what as to my honey harvest? Colonel Newman and Mr. Lowe will not expect much from an experimental apiary so harassed and tortured as mine has been. Nevertheless I obtained the following top-honey of the most beautiful purity, without a single particle of brood or bee bread in it; 8 lbs. 4 ozs. from C, the Italian stock; 17 lbs. 9 ozs. from D, the hybrid Italian; 22 lbs. 1 oz. from E; and 8 lbs. 2 ozs. from I: the greater part of which has been sold at 1s. 6d. per lb. Besides this I broke up a straw hive from which 9 lbs. of the purest comb was taken in a cap, and about as much of good but somewhat inferior honey from the hive itself, in all 74 lbs. nett. I do not think I have reason to complain on a review of the experiences of the season, although it must be admitted that I have had enough of disappointment too. In another paper I shall have some further comments to make on the experiences of the season.—B. & W.

THE BEE SEASON IN NORTHUMBERLAND.

HAVING read the announcement of a very good honey harvest this year in the south, it may be interesting to your readers to know that here (in Northumberland) it has not realised the expectations which the warm dry summer made us entertain. The bees certainly did better during the summer than they have been known to do for many years. The hives mostly went up to the moors very heavy, and from that cause lamentable was the account of hives broken down in their journey. Some cottagers took off tops, before they sent the hives to the moors, weighing between 20 lbs. and 30 lbs—a prosperity almost unheard of here, as our chief harvest is gathered from the heather. We cannot hope to rival the supers of 50 lbs. or 112 lbs., mentioned by your correspondent, Mr. Fox, of Exeter; but the result of the bees' journey to the moors is most unsatisfactory. I cannot hear of any hive which has increased more than a few pounds in weight, and that only by guess-work. The general complaint is that they have returned lighter than they went. The wet and windy weather set in about the middle of August, just after the bees had been sent, and

they had only three or four good working days during their sojourn on the hills. However, the good summer has made them all "keepers," as the term is here, and we must live in hopes of a better autumn season next year to revive the stocks and the spirits of the Northumberland bee-keepers, now suffering under a fourth bad year.

Can any of your readers inform me whether *Melilotus leucantha* is so favourite a flower with the bees as Mr. Wood and Mr. Westwood in their little works on bees assert? I have sown a quarter of an acre with it. It flowers luxuriantly and long, for it is still in flower, but the bees do not work on it nearly so much as on borage.—W. C. ELLIS, *Bothel*.

HOW ITALIAN QUEENS ARE SOMETIMES LOST.

ITALIAN queens are sometimes lost soon after they have been introduced to colonies of black bees.

When a queen is caged before her introduction to a strong colony, queen-cells are usually commenced, and sometimes are not destroyed after she is liberated, the bees swarming out with the Italian queen, and leaving a part of their number to take care of their old home. This is not an uncommon occurrence in strong stocks during the swarming season, and it sometimes occurs after all natural swarming is over.

On the 13th of August I destroyed a number of queen-cells, after an Italian queen had been liberated and accepted by a strong colony of bees. On the 20th a swarm issued with the Italian queen, and I found two more sealed queens, but not an egg in the combs.

On the 17th I removed an old queen from a very strong colony, giving them a caged queen, which was liberated in forty-eight hours. On the 21st, finding many queen-cells and no eggs, and not being able to see the queen, I concluded that she was lost. Making a more careful examination on the 24th I saw the queen, and removed twelve royal cells; there were no eggs in the hive. I have not made sufficient observations to determine whether queens, under such circumstances, generally decline to lay eggs. Thirty-eight hours after the removal of the royal cells above-mentioned, I found that the queen had laid a large number of eggs.—L. L. LANGSTROTH, *Oxford, Butler Co., Ohio, (in Prairie Farmer.)*

OUR LETTER BOX.

MANCHESTER POULTRY SHOW (*A Yorkshireman*).—We differ from you entirely. We consider the prize list very liberal; but we deprecate the Show being held on days which include Christmas-day.

BROODY HENS (*J. W. C., Halifax*).—There is no method of preventing hens from sitting. The desire to do so comes naturally when they have done laying. It is nature's rest, and although they may be prevented from sitting, they will not lay any the sooner. Drive them about constantly with the other fowls, do not let them get in any corner. If they show a desire to sit in any particular place shut them out of it, and keep them on the move.

ISABEL PIGEONS (*Columba*).—I do not know any variety of Pigeon by this name. On the continent Isabel is used to designate a pale buff or yellowish-cream colour. I believe, however, that some Pigeons have lately been exhibited under this title. As such, perhaps, some breeders of them will say what are their points.—B. P. BRENT.

SKELETONISING LEAVES (*Langholme*).—A work was published in America on this subject, with the taking title of "The Fairy Bonquet," but it is worthless and gives no available directions for skeletonising. We know of no other publication on the subject.

MOVING HIVES (*T. E. Robson*).—We do not deem it necessary or even advisable in this climate to remove bees from their ordinary stands and shut them up during winter. If, notwithstanding this, you decide on trying the experiment, the removal should take place before very severe weather sets in, and the confinement terminate as soon as frost and snow have disappeared. In America Mr. Quinby appears to have carried out this mode of wintering bees to the fullest extent. He inverts ordinary hives and removes the top-boards from those having either bars or frames, not confining the bees to their hives, but trusting to perfect darkness to prevent their straying. In this way he boasts of having kept bees uninjured during five months. For several years he made use of a small bedroom in which he put about a hundred stocks. He describes it as being lathed and plastered, but with no aperture for air except what was admitted through the floor, which was single and laid rather close, though not matched. In 1849 he built a room without any windows for this especial purpose, 16 feet square and 7 feet high. A good coat of plaster was put on the inside, and a space of 4 inches between the ceiling and laths was filled with sawdust. Under the floor was a passage for the admission of air from the oorth, and another overhead for its exit, which could be closed or opened at pleasure. This room was divided by a partition near the centre in order to prevent disturbing the whole by the admission of light when removing the stocks in spring, and the hives were arranged in tiers one above the other on movable shelves. We do not know where you can obtain a Ligurian queen.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 48.2°, and its night temperature 34.5°. The greatest heat was 59°, on the 20th, 1844, and 21st, 1833; and the lowest cold, 9°, on the 23rd, 1858. The greatest fall of rain was 0.87 inch.

MEMORIAL OF MR. DONALD BEATON.

E have received several letters inquiring if it is intended to erect any monument as a memorial of Mr. Beaton, and asking us to receive subscriptions for that purpose. Most

readily do we assent to receive such contributions, and will undertake to have them expended in the erection over his grave of such a solid yet simple record as the fund may justify.

Most gratifying is it to us, as it must be to all Mr. Beaton's friends and admirers, to find how generally and how highly appreciated he was by those best qualified to estimate his worth, both as a private and public character. The metropolitan and provincial press coincide in details of his high merits, and in expressions of regret for his loss.

LIFTING THE ROOTS OF VINES, AND RENEWING THE BORDER.

WHEN this operation is commenced, its completion should be accomplished with as little delay as possible. It is, therefore, necessary to have in readiness, before the old border is interfered with, the amount of material that shall be needed for drainage and for the formation of the new border. When the subsoil is clay, it is always advisable to concrete the bottom before the draining material is laid on, and gravel and lime should be included in the mixture. A main drain should run parallel with and at the extreme front of the border, and cross drains from the front of the vinery should run into the main drain at intervals of 6 feet, and, of course, a good outlet should be secured for the whole. Four-inch-tile drains will be sufficient. These, with as many brickbats or small stones as will form a layer 1 foot deep all over the bottom, and a few barrowloads of coarse gravel with the sand sifted out of it to blend with the brickbats or stones, will be all that is required for the formation of the site on which the border is to rest.

The border itself, to be what is considered of first-rate quality, should consist of friable turfy loam taken from an old pasture to the depth of 4 inches, herbage included. To eight cartloads of loam add two of mortar rubbish, one of horse-droppings, and 4 cwt. of inch bones. As our correspondent, "C. V.," has charcoal at command, he may substitute it for the mortar rubbish, or a cartload of each may be added instead of the two of mortar alone. The loam should be chopped up with a spade, and the whole thoroughly mixed together and protected from rain in a place close at hand till it be required.

Though such a compost as this is recommended, I am far from desiring to lead the inexperienced to suppose that Grape-growing is not to be attempted, or that the roots of Vines are to be left undisturbed in cold, wet borders till they can command such a border to the very letter as has been described. The nearer they approach

to it, however, the better. If, for instance, the loam at command is heavier than that which deserves the name of friable or turfy, then more mortar rubbish or charcoal, or both, should be applied; and when the two latter cannot be had, a third of the soil itself may be charred, or even burned, an expedient which I have frequently had to adopt myself. Even where nothing in the shape of turf from an old pasture can be had, very good Grapes can be grown with moderately light common garden soil having the same amount of the other ingredients mixed with it, or more or less of them, just in proportion as the soil is stiff and likely to become consolidated, or the reverse. Any composition that is free and open, and moderately enriched with manure, produces very good Grapes, and no discouragement should be thrown in the way of any one who can form his border of such, when that which is considered best cannot be more closely imitated. An amateur friend near here has done wonders with a border of little more than black sand close to the sea. Too much water about the roots was next to impossible, from the nature of the soil, and the secret of his success lay mainly in rich top-dressings.

Supposing, then, that the time for lifting the Vines has arrived, which, as has already been stated, in the case of Vines that can be cleared of their crop before they become dormant, is early in autumn. But when the reverse of this is the case, and the crop is a late one, the operation is to be performed in spring in preference to winter. In as far as the operation of lifting the roots is concerned, the time of doing it makes no difference, although in several points the after-treatment required at the different seasons varies considerably, and will, therefore, be separately referred to.

The first thing that must be done is to remove the whole of the inert surface soil down to the roots of the Vines. Then a trench should be taken out along the front of the border deep enough to be below the roots. The removal of the whole soil should then be effected with as little injury to the roots as possible. Every rootlet that can be saved will contribute its own share towards the success that is to follow. After the trench is opened, the soil must be gradually and carefully worked away from the face, and the trench should be constantly cleared of the loose soil. There are no better tools for this purpose than a four-pronged steel fork, and a sharp-pointed piece of hardwood stake. Any attempt that may be made to hurry forward such an operation as this is sure to be attended with a corresponding injury to the roots. No large slices of the border must be taken off at a time, but it must be gradually picked, forked, and crumbled away. Yet the operation should be completed as quickly as it can be done, so that the roots should be as short a time as possible out of the ground. Therefore, as many hands as can work without being in each other's way should be employed.

As soon as the roots are all liberated, they should be covered up carefully with damp moss and mats, to prevent their suffering from the weather, till the new border is ready for them.

The bottom or site for the border should be gradually sloped off from the front of the vinery to the extreme front of the border, where the main drain is to be laid, and if practicable give it a fall of 1 foot in 12. When it is necessary from the bad subsoil to concrete the bottom, in a case of this sort I have, for the sake of getting on quickly with the work, formed a firm surface for the drainage to rest on, by first putting a layer of stone of the size of the road metal over the surface, and beating it into the clay, and then placing another layer somewhat thicker over this, and binding the whole up with concrete. This at once gives a bottom on which tiles and brickbats can be laid without tearing up the fresh-laid concrete. The tiles and drainage being all adjusted as already described, put a layer of thin turf over the whole, with the grass downwards, if such can be had; if not, a thin layer of straw, or the roughest part of the soil. While the drainage is being completed, I would advise that upright pipes be fixed close to the front wall of the vinery, and connected with the tile drains in the bottom, and a similar series of funnels along the front in connection with the main drain. This will in hot weather give the power of admitting a circulation of air beneath the border, and the pipes can be plugged up at night. In cases where the border extends inside the vinery, the one set of air-holes should, of course, be inside the house, when the circulation of air will be more effectual from the difference of temperature.

The new soil should be laid on in layers, and rather firmly beaten down with a closely-pronged fork to prevent its subsiding much and dragging down the roots of the Vines. When filled up to within 10 inches or a foot of the desired level, the roots of the Vines should be disentangled and carefully and regularly spread out over it. Immediately over them place a thin layer of the finest of the soil, and then fill up with it, just as it comes, to the level, which should always be a little higher than is ultimately desired, to allow for subsiding, but never cover the roots deeper than 10 or 12 inches.

The depth of border should be at front of vinery 2 feet 3 inches, sloping off to 2 feet at the extremity of the border.

Vines that are thus lifted and replanted by the middle of September, when they are still in leaf, and the temperature of the soil still high, should have the new border snugly covered up with a foot deep of some nonconducting material, such as fern, straw, or leaves, with a covering over all of wooden shutters or straw, to completely protect it from rain. This will prevent the radiation of heat, and protect the young rootlets made in autumn from wet in winter. Immediately, or even before the Vines are lifted, a shading of some thin material, such as tiffany, should be fixed on the roof of the vinery, to keep the leaves from being exposed to the full sun. The house should be kept close and moist, to prevent as much as possible the leaves from flagging. Generally, some of the oldest leaves drop off, but with attentive management in the matter of keeping the atmosphere moist and rather close, root-action soon commences, and the laterals will make fresh growth, which should be encouraged for a few weeks. After the Vines have recovered the shock the shading should be removed, the atmospheric moisture reduced, and more air admitted. Should the weather be cold, as it often is about the end of September and beginning of October, fire heat should be applied, particularly during cold nights.

Vines requiring such radical treatment as this are generally not well ripened; and if a crop is expected next season, and for the improvement of the constitution of the Vines, fire heat should be applied with a regular but not violent circulation of air throughout October, to ripen the wood, which object for the present is next in importance to getting the Vines to make fresh roots in their new bed of earth.

In spring, and just as the Vines begin to swell their buds without fire heat, a bed of warm leaves, or leaves and stable-dung mixed together, should be placed over the surface of the border in place of the winter covering put on in autumn. This will throw a little heat into the border and assist the progress of the Vines very much. The Vines should not be hurried in their progress, and only a light crop of fruit should be taken, even should they show plenty of fruit, which must not be too sanguinely looked for.

When the operation of lifting is performed in spring when the Vines are about to start, the bed of hot fermenting

material should be applied immediately the work is done. The Vines should be slung down further from the glass than in ordinary cases; and instead of forcing them on allow them, so to speak, to feel their way. They must be expected to break more weakly than usual; and in order to assist the young growths to support themselves till the roots are brought fairly into play, a moist atmosphere must be kept up, particularly during bright weather, and they will soon establish themselves, and bear a moderate crop of fruit. The bed of leaves should not be removed from the border till midsummer, and then a slight mulching of dung should be substituted. Where leaves cannot be procured, as is the case with many amateurs, a load or two of stable-manure will answer the purpose; and wherever that is not attainable the next best thing to do is to cover the border with something that will prevent chilling winds and rains from influencing it.

In all other matters in the routine of culture, our correspondents must consult works on the subject, and it is to be hoped that what has been said will be of service to them, and others similarly situated, who have not had experience in lifting the roots of Vines.

D. THOMSON.

THE CHRYSANTHEMUM SHOW AT THE AGRICULTURAL HALL.

THIS took place on Wednesday, Thursday, and Friday, last, and considering that it entirely owed its existence to the exertions of the growers, both amateur and professional, in the immediate neighbourhood of Islington, it must be regarded as a very successful beginning. Not only were the plants fine examples of culture, but the cut blooms, both as regards size and form, reflected the greatest credit on the growers. Some little confusion, no doubt, existed at first, though not more than could have been expected in classifying and arranging so vast a body of materials as poured in; but through the active exertions of Mr. Jeffries, the pains-taking Secretary of the Amalgamated Society, all was soon brought into order.

Although it could have been wished that the Exhibition had been spread over a less extent, still the effect of the display of specimen plants occupying the body of the Hall, was excellent, especially when seen by gaslight. The Pompones in particular, being studded with innumerable red, white, and yellow flowers, seemed even more attractive by night than by day, and when viewed from the galleries had a most charming appearance, whilst in the galleries themselves were long lines of cut blooms, chiefly of the large-flowering kinds.

In six plants of the large-flowering varieties, Mr. Glover, gardener to R. C. Lepage, Esq., Brixton, was first, with Dr. Maclean, Trilby, a magnificent plant of Jewess (orange red), Vesta, Prince Albert, and Chevalier Domage, all of which were very compact. Mr. George, gardener to Miss Nicholson, Stamford Hill, was second.

In threes, Mr. Monk, of Tottenham, was first, with a fine plant of Christine, Rifleman, and Defiance. Mr. Weston, gardener to D. Martineau, Esq., Clapham Park, came in second, having fine plants of Chevalier Domage and Golden Christine. Prizes were also awarded to Mr. Glover, Mr. George, and Mr. Whitbread.

In six Pompones, Mr. Beecher, gardener to T. Chandler, Esq., Shooter's Hill, was first; Mr. Weston, second; and Mr. Ward, third; and among the plants which they exhibited were beautiful examples of Salamon, Requioui, Helena, Cedo Nulli, and Général Canrobert.

In three Pompones, Mr. Whitbread had the first prize; Mr. Beecher being second; and Mr. Ward, and Mr. Monk, the third and fourth respectively. Among these exhibitions were excellent examples of Golden Cedo Nulli, Bob, Cedo Nulli, Général Canrobert, and other well-known kinds.

Excellent groups were exhibited by Mr. Whitbread, Mr. George, and Mr. Ward, who each received prizes.

In the Nurserymen's Classes for specimen plants, Mr. Forsyth, and Mr. Oubridge, of Stoke Newington, were respectively first and second throughout. In that for six plants, the former had Aregina, Defiance, Christine, Alma, Annie Salter, and Rifleman; and in threes, Prince Albert, crimson, very fine; Golden Christine, and Insigne.

In six Pompones, Mr. Forsyth contributed Général Can-

robert, Duruflet, Cedo Nulli, Hélène, Rose Trevenna, and La Sultana, all of which were very evenly grown, neatly trained, and covered with bloom. Mr. Oubridge had *Trophée*, mottled rose; and others already named.

In threes, Mr. Forsyth had fine specimens of *Hélène*, *Général Canrobert*, and *Lilac Cedo Nulli*. Both of the above exhibitors also brought large groups of well-grown plants, which contributed much to the effect of the Show.

In the Amateurs' Classes, Mr. Howe, of Shacklewell, was very successful, gaining first prizes both in the Class for six plants, and in that for three, with excellent plants of *Lord Ranelagh*, *Draco*, *Golden Christine*, *Chevalier Domage*, *Annie Salter* (very fine), and *Alma*.

In Pompones, Mr. Parker, of Stratford, had remarkably fine plants, upwards of 3 feet across, of *Général Canrobert*, *Cedo Nulli*, *Golden Cedo Nulli*, *Duruflet*, *Lilac Cedo Nulli*, and *Andromeda*. He received the first prize in the Class for sixes, Mr. Bolton being second, and Mr. Howe third; and in the Class for three, Mr. Bolton took the first prize, and Mr. Parker the second.

Mr. Howe also contributed a fine group of pyramid Pompones, some of which were perfect models, and in beautiful bloom, and large-flowering kinds, both on tall stems and trained in bush form.

In Specimen Plants, Mr. Monk had a first prize for a very large and fine plant of *Golden Christine*, Mr. Howe being second with *Lady Harding*, also fine.

In the Pompones Class, Mr. Forsyth and Mr. Bolton took the two highest prizes for *Saint Thais*, and *Golden Cedo Nulli*, both of which were good specimens. Some very good pyramid Pompones were also shown by Mr. Ward, and Mr. George, among which were included *Mr. Astie*, *Reine des Anémones*, *Marguerite de Wildemar*, and *Antonius*. Mr. Ward had a first prize for these, and Mr. George a second.

Of Cut Blooms, which were exhibited in the galleries, there was a most extensive display, though, owing to the great length of the tables, the stands were not so close together as desirable for producing effect.

In twenty-fours, Mr. Monk had the first prize for a fine stand, among which we remarked *Queen of England*, *Cherub*, *Themis*, *Jardin des Plantes*, *Alfred Salter*, *Mrs. W. Holborn*, *Lysias*, *Cassandra*, *White Globe*, *Nil Desperandum*, *Novalty*, and *Goliath*. Mr. Ward was third, and Mr. George fourth, in the same Class.

In twelves, Mr. Monk was again first with beautiful blooms of *Queen of England*, *Jardin des Plantes*, *Cherub*, *Themis*, *Goliath*, *Lady Harding*, *Novalty*, *Lysias*, *White Globe*, and *Alfred Salter*. Mr. George was second, Mr. Ward third, and Mr. Wyness, *Buckingham Palace Gardens*, and Mr. Salmon, equal fourth.

In sixes, Mr. Monk was also first; Mr. Rowe, *Stamford Hill*, being second.

Large-flowering Anemone varieties were well shown by Mr. Ward and Mr. Monk, who were awarded the first and second prizes for that Class. Among the sorts they exhibited were *George Sand*, *Gluck*, *Marguerite d'Anjou*, *Louis Bonamy*, and *King of Anemones*.

In the Class for Anemone Pompones, the positions of the above exhibitors were reversed, both, however, showing very creditably.

Collections of Cut Blooms were contributed by Messrs. Monk, Rowe, George, and others; and in the Nurserymen's Classes, by Mr. Cattell, of Westerham, who had fine examples of *Queen of England*, *Jardin des Plantes*, *Beauty*, *Aimée Ferrière*, *Chinese Orange Incurved*, &c.; also, by Messrs. Wilkinson, Forsyth, Merrey, and others.

Large Anemone-flowered kinds were also well represented, especially by Mr. Cattell, who had some immense blooms of *Lady Margaret*, each about 5 inches across; *Handel*, a fine dark rose; and *Louis Bonamy*, remarkably fine. In Anemone Pompones, Mr. Forsyth took the lead.

In the Amateurs' Classes for twenty-four and twelve blooms, Mr. James and Mr. Slade were respectively first and second in both, Mr. Robinson, *Islington*, taking an equal first in the Class for twelve. Mr. Cakebread, who was first for six blooms, had a remarkably fine *White Globe*, *Aregina*, and *Jardin des Plantes* being also fine.

In the *Islington* Classes, Mr. Jeffries, the Secretary of the Society, and Mr. Robinson, were the principal prizetakers.

Anemone-flowered varieties of both kinds were also very successfully shown by Messrs. Pryer, James, Butt, and Hilleary.

In New Varieties, Mr. Forsyth was awarded the first prize, for *Duchess of Buckingham*, white; *Beverley*, a fine white; *Her Majesty*, a very pretty blush; *Prince Louis of Hesse*, and *Cleopatra*, rosy blush; *Antonelli*, brownish-salmon. *Golden Eagle*, dull red tinged with gold, came from Mr. Moxham.

Several pretty bouquets of cut blooms, interspersed with Ferns, &c., were shown by Messrs. Cattell, Glover, and others.

Miscellaneous articles were shown by Messrs. Butler and McCulloch, and Hooper & Co., of Covent Garden, consisting of Hyacinth-glasses, baskets of Everlastings, ornamental Grasses, &c.; and Messrs. Sutton & Sons, of Reading, had a very extensive collection of Gourds, Grasses both ornamental and useful, Potatoes, and seeds.

Messrs. Cutbush, Williams, E. G. Henderson, Videon, and Grimbley, contributed large numbers of fine-foliaged plants and evergreens for the decoration of the sides of the Hall.

A group of standard Pompones, with pyramidal heads, from Mr. Whitbread, and which were covered with blooms, formed beautiful objects, which we omitted to mention at the proper place.

FLOWERS OF THE PAST SEASON.

VERBENAS.

"I WISH you would come up and have a hanging-day." Such was the salutation wherewith a friend and neighbour greeted me, who is known all the world over as the first *Fuchsia-raiser* of his day, and of some *Verbenas* which still hold their own in the midst of novelties over and over again announced to drive them out of the field; and as his garden contains nearly all *Verbenas* worth growing, and I have generally a pretty fair collection of the novelties of the season, I think we can manage to form a pretty good opinion of the worth or worthlessness of the claimants to public favour: and so a hanging-day was named. It so happened that when we met for the purpose another friend came also, who, though now the rector of a London parish, had once been our neighbour, and he is an excellent florist and an especially good judge of *Verbenas*. Thus, with Mr. Banks's intelligent gardener, we formed a quartet, no way influenced, I think, by partiality—with no flowers of our own to decide upon, but simply to say what we thought about *Verbenas* in general. Previous to entering on our task we had a passage of arms on a few points. One was the failures of the *Verbenas* we were met to decide upon. For the past three years this failure has taken place. Formerly nothing could be more luxuriant than these *Verbenas*; but during the past three or four years the failures have been lamentable: the plants become rapidly mildewed—they are infested with thrips, and with another kind of insect, which seems to eat the cuticle of the leaf and completely disfigures the plant. Under a combination of such circumstances the plants in many instances pine away, spaces are made in the beds, and the appearance of the garden spoiled. Can any of your correspondents suggest a reason for all this? The plants put out are perfect models, have been carefully struck in the spring, are not planted out early (the end of May or beginning of June being about the time selected), and yet they will die. The ground is carefully prepared, and every attention is paid to them. Then, again, we were each to name a dozen of the best *Verbenas* for general purposes, bedding, and exhibition; and, as showing how much alike our tastes were, and how superexcellent some sorts are, I may mention that eight *Verbenas* in each of the four lists were identical. The judgment given in the following notes may therefore, I think, in general be relied upon; although, doubtless, like all other judgments, there are mistakes, but at any rate there are no wilful ones. Another point we had also to decide was what *Verbenas* out of the vast number grown we should propagate and what discard. Here again opinions may clash with our judgments, but I give up all idea of getting people to be of one mind on the merits of a flower. Look at *Roses*, for example. I saw the other day somewhere a list of good *Roses* of 1861, and

amongst them was Jean Baptiste Guillot, a flower with a bud as hard as a cricket-ball, which one can never get to open. And so it will always be: we must only give our own judgment, and let others modify it according to their own tastes.

In giving the following notes I have tried to distinguish by B and E those which are suited for bedding and exhibition purposes. A bedding *Verbena*, I think, ought to be short-jointed and free-flowering, the colours distinct and not diverse, eyed flowers being objectionable; the size of the pip and shape being of less importance, although where all the points of excellence are combined so much the better. For exhibition the shape and size of the pip and truss are of the first importance. Edged flowers are here desirable, although they require self-coloured flowers to relieve them in a stand. I will take them as I did the *Roses*.

PERKINS & CO.

Lord Leigh, E.—Brilliant scarlet, with square yellow eye. This I regard as the finest flower of the year. It is, indeed, in colour very like *Colossus* and *Foxhunter*, but is distinct from them. Several times it has been, I fancy, exhibited as such, and in more than one instance has been detected. In the garden it is easily distinguished from either of them by its robust habit; for this reason it will, I think, make a good bedding plant also.

DOWNIE, LAIRD, & LAING.

Lord Claver, E.—Beautiful in colour—viz., a bright purple, but I fear it does not bear a sufficiently good truss ever to make a good exhibition flower. It may, I think, fairly have another year's trial.

TEEN.

Rugby Hero, E.—Light rose with carmine eye. Some strange mystery hung over this flower, for it was clearly none other than *L'Avenir de Ballent*, which is unquestionably one of the very best exhibition flowers we have, and for those who do not dislike eyed flowers in their bedding-out plants it is excellent also. The foliage is good, the flowers abundantly produced, and the individual truss large.

E. G. HENDERSON & SON.

Admiral Mitford, E.—Rich scarlet crimson flower with yellowish eye, a most refined flower. The growth is also short and good, but too flat for bedding purposes. It will be indispensable for the exhibitor, and may well be grown in the most select collection.

White Lily.—Good for neither exhibition nor bedding. Nothing can better show the impossibility of determining the future career of a flower than this. I know that Mr. Henderson thought very highly of it, and that the somewhat glowing description in his catalogue was a reflex of his own judgment. The flowers are very small as well as the pip.

Blue King, B.—Somewhat in the style of *Purple King*, but lighter in colour. Likely to be an acquisition.

Eulalie.—Faint and washy in colours. Condemned.

Effie Dears.—Scarlet crimson with white eye. At one time I thought this would prove a good flower, but I fear not.

Glendower.—Dull purple. Of no use.

Nora.—Reddish-purple. Of this the same must, I fear, be said.

Peep o' Day.—Rosy salmon, with dark eye. After much consultation we came to the conclusion that this, too, must go into the black list.

Stella.—Burns at the edge, at least with us here it did.

Princess.—Violet crimson. This also we condemned.

St. Clair.—Plum-coloured, somewhat in the style of *Purple King*, but I fear not likely to be kept in our lists.

LOW & SON.

Flora.—Pink, with white centre. Poor.

Ruby, B.—Deep ruby colour; of excellent habit, very free-flowering, and likely to be useful for bedding. It will, too, if I mistake not, often be found in the stands of exhibitors.

Rosalie, E.—Deep salmon rose. A good flower, which will merit another trial.

Purple Emperor.—Good in colour, but I fear its growth is too small and delicate ever to make it a good bedding plant.

Amaranth.—Another indifferent grower. The colour is good, but its habit will condemn it.

Chieftain, E.—Scarlet, white centre. A very good and effective flower, bright in colour, and with large pips.

Arkansas.—Somewhat dull in colour, and therefore condemned.

The Bride.—Light rose; somewhat like *Ida*, but not so good.

TURNER.

Miss L'Anchère.—Not novel in colour, and therefore condemned.

Grande Boule de Neige, B.—This promises to be a very fine flower. The colour is pure and the habit good; not nearly so straggling as *Mrs. Holford*, and much more abundant in blooming.

Ruby King, B.—A good-habited flower of a bright ruby colour. The flowers are very freely produced, and I have little doubt that it will be a very desirable variety.

Fairy.—Too faint and dull.

BULL.

The Clipper, B.—A good flower, intermediate in colour between *Lord Raglan* and *General Simpson*. It is also of good habit, and will, I think, be a useful flower.

Such were the results of our notes. It will be seen, then, that the only flowers of the past season that we really considered first-rate were *Lord Leigh*, *Admiral Mitford*, *Ruby*, *Chieftain*, *Grande Boule de Neige*, and *Ruby King*; that of second-rate flowers there were *Lord Craven*, *Blue King*, *Rosalie*, and *The Clipper*; and that the rest were considered to be out of the field altogether. There were, I know, other *Verbenas* advertised, but we have not seen them, and I am inclined to think that they are not in any way acquisitions. They have not appeared as such at the metropolitan exhibitions, nor have I heard of any one who so considers them. I have not named *L'Avenir de Ballent*, as it was a flower of the previous year. It may, perhaps, serve as a guide to others if I add to this the list of those which we determined to retain:—*Foxhunter*, *Lord Raglan*, *Brillante de Vaisse*, *Nemesis*, *Géant des Batailles*, *Admiral Dundas*, *General Simpson*, *Miss Hughes*, *Madame Mahar*, *alias Madame Hermann Stenger*, *Mrs. Harrison*, *Striata Perfecta*, *Reine des Amazones*, *Fairest of the Fair*, *Mrs. Holford*, *Snowflake*, *Le Bon Nicholas*, *Madame Jenson*, *Faust* (this splendid flower I do not see in any of the catalogues, it is one of the very best we have), *Miss Elphinstone*, *Zampa*, *Topsy*, *Thormanby*, *Madame Zoulier*, *Grand Eastern*, *Paul Tircas*, *Madame de la Nalline*, and *Victory*.—D., Deal.

STOKE NEWINGTON CHRYSANTHEMUM SOCIETY.

THE seventeenth annual Exhibition of this Society took place on the 9th and 10th inst., and the display as usual was excellent both as regards plants and cut blooms. Fine blooming plants were ranged all round the room, whilst the central portion was occupied by the cut blooms and a row of pyramid Pompones, which in the denseness of their growth offered a marked advance on those seen at last year's Show.

For six plants the prize was awarded to Mr. Forsyth, nurseryman, Stoke Newington, who had *Prince Albert*, *Defiance*, *Alma*, *Annie Salter*, *Aregina*, and *Lady St. Clair*. Mr. Howe, exhibiting in an extra class, was first with excellent plants of *Lord Ranelagh* (orange red), *Lady Harding*, *Orange Perfection*, *Draco*, *Hélène*, and *White Christine*.

In Six Pompones, Mr. Forsyth was first with capital plants of *Cedo Nulli*, *Durand*, *Golden Cedo Nulli*, *Général Canrobert*, *Hélène*, and *Rose Trevenna*. Mr. Howe was second. Excellent single specimens of Mr. Astie and Annie Salter were also shown.

The three pyramid Pompones, *Général Canrobert*, *Cedo Nulli*, and *Hélène*, from Mr. Howe, were beautiful examples of that style of training; and those from Mr. George, gardener to Miss Nicholson, Stamford Hill, who was second, were also good.

Of cut blooms there were several very good stands. In twenty-fours, Mr. Heals, of Westerham, had the first prize, having amongst yellows *Plutus* and *Jardin des Plantes*; *Cassy*, orange; *Beauty*; *Queen of England*; *Mrs. W. Holborn*, and *Lacium*; *Her Majesty*, a new silvery blush; *Alfred Salter*, *Rifleman*, *Raymond*, *Hermione*, and *Fabius*.

Mr. Slade was second, having *Beverley*, a cream white; and *Aimée Ferrière*, a charming variety, white delicately tipped with pink.

In twelves, Mr. Heals was first, and Mr. Moxham was second; in sixes, Mr. Cornwall, Kingsland, had very fine blooms of *White Globe* and *Jardin des Plantes*.

Of *Anemone*-flowered varieties there were good stands of both large-flowering and *Pompone* varieties. In the former, George Hock, Gluck, Lady Margaret, and Louis Bonamy were well shown. In the latter some fine examples of *Madame Sentir*, *Madame Montels*, *Antonius*, and *Marguerite de Wildemar*.

As on previous occasions, the getting-up of the Exhibition was entrusted to Mr. Howe, the Secretary of the Society, and he deserves every credit for the pains which he has taken and the courtesy which he exhibits in conducting this, one of the most pleasing local shows near London.

ARE ORCHARD-HOUSES FORCING-HOUSES?

Would you inform me whether you would consider fruit grown in orchard-houses forced? I heard a discussion at a provincial show whether it should be called forced or not. It was eventually decided that it is forced, but for my own part I cannot see that it is. I should like, however, some higher authority to decide the question before I conform to the same opinion; for forced fruit I consider to be that which has had artificial heat applied in some form or other, and not that which has had merely protection, as I take orchard-houses give.—A. P. Z.

[We consider the provincial society's decision wrong. All fruits grown against a wall with canvass stretched before them would as justly be called forced as the fruits grown in an orchard-house, where, of course, no artificial heat is applied. In both cases means are adopted for retaining the heat afforded by the sun. The fruits are protected, not forced.]

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.—Nov. 10th.

FLORAL COMMITTEE.—This Committee held their meeting on this occasion in the council-room, much to the satisfaction of its members, and to the advantage of the specimens exhibited.

Mr. Veitch sent six specimens of *Lycaste Skinneri*, plants imported this year—they were distinct varieties, and were much admired, although but slightly differing from other varieties now in cultivation: *Polypodium album punctatum*, a new and very beautiful distinctly-spotted Fern, had a first-class certificate; *Davallia diversifolia Hillii*, which had received a first-class certificate on a former occasion; *Eranthemum tuberculatum*, a valuable plant from its flowering at this season of the year; its white Jasmine-like flowers and compact foliage gave it a very pretty character—a second-class certificate had been awarded at a previous meeting.

Mr. Earley sent out specimens of a seedling *Begonia*, with bright deep rosy flowers, strongly resembling *Begonia Sandersi* semperflorens.

Mr. Bull exhibited *Anectochilus zebrinus*, a very young and weakly specimen; a species of *Trichomanes*, from Trinidad, not sufficiently grown to prove its character; *Lindsea* species from Trinidad, a very beautiful plant, which was awarded a first-class certificate; two varieties of *Caladium Lowii*, one of which was named *reticulatum*.

Mr. Cattell, of Westerham, had *Picea pectinata pendula*, one of the drooping varieties, a form which is not uncommonly found among other plants of this family. Cut specimens of an *Ipomœa*, from Natal, with dull pink flowers, came from the Society's garden at Chiswick. The seed of this plant was sent home by Mr. Cooper. It has flowered in one of the stoves; unless it will bear a cooler temperature it will be of no value.

A *Chrysanthemum*, called *Late Dragon*, one of Mr. Standish's Japan varieties, was commended. Although not a florists' flower, it is very showy, and its bright yellow flowers, with their dragon-mouthed or lacinated florets, together with its deep green broad foliage, make it a useful

decorative plant. These Japan varieties have the property of lasting longer in flower than our English *Chrysanthemums*. The plants, only late cuttings, each produced one very fine flower. We noticed two superb specimens of *Chrysanthemum Queen of England*, the white and yellow varieties. These were brought out of the conservatory from a collection which had been grown at the Chiswick Gardens, the plants being grown for the experiment of producing one large flower, which has admirably succeeded. A visit to the conservatory will be well rewarded, for finer flowers of the *Chrysanthemum* have never been seen in cultivation. They would doubtless have made a conspicuous feature at any of the meetings at which this flower is specially patronised.

FRUIT COMMITTEE.—John Kelk, Esq., in the chair. There was a fine display of fruit at this meeting, one of the best that has been seen at the Committee for a considerable time past; and the pleasure of the meeting was greatly enhanced by its being held again in the council-room, whence it never ought to have been removed. It may not be generally known that for the last twelvemonth the Committee has been poked about in all sorts of out-of-the-way nooks and corners. In the cold spring months they might have been seen in one of the cold draughty corridors of the Great Exhibition building, wrapped in great coats, and huddling together to keep each other warm; while in the burning heat of summer they were elevated into the upper gallery of the conservatory, there to be broiled, while two and sometimes three elderly gentlemen were in undisturbed possession of the council-room, devouring as much of the morning papers and the monthlies as they could get for nothing.

There were various prizes offered at this Meeting, Class A being for the best three dishes of dessert Apples, any variety. In this class there were eight entries, some of which contained several fine specimens of the varieties exhibited. Mr. Spivey, of Hallingbury Place, Essex, sent fine specimens of *Ribston Pippin*, *Fearn's Pippin*, and *Margil*, but, unfortunately, they had been in contact with hay or some other material that destroyed their flavour. Mr. Hall, gardener to Capt. Tyrrell, Fordhook, Ealing, had very excellent specimens of *Ribston Pippin*, *Blenheim Pippin*, and *Autumn Pearmain*; but they all yielded to the *Eldon Pippin*, *Cox's Orange Pippin*, and *Mickleham Pearmain* shown by Mr. Whiting, of the Deepdene, and to which the first prize was awarded. The second prize was obtained by a collection which was unaccompanied by any letter or address. It consisted of *Fearn's Pippin*, *Cockle Pippin*, and an unnamed variety.

In Class B there were nine entries, and many of them contained remarkably fine specimens. The *Chaumontels* of Mr. Hall, of Fordhook, were so large and handsome that they were awarded a certificate of commendation. Mr. Spivey had fine specimens of *Glou Morcean* and *Passe Colmar*; and Mr. Curd, of Sulhampstead House, exhibited very fine *Beurré Diel*, *Passe Colmar*, and *Ne Plus Meuris*. The first prize, however, was awarded to Mr. Cox, of Redleaf, for *Glou Morcean*, *Chaumontel*, and *Winter Nelis*, all three of which were richly flavoured, as were also the *Beurré Superfin*, *Winter Nelis*, and *Marie Louise* of Mr. Whiting, of the Deepdene, which received the second prize.

Class C was for the best dish of Grapes having a Muscat flavour, and the first prize was taken by Messrs. Lane and Son, of Berkhamstead, with *Muscat Hamburgh*, and such a bunch! Some good judges considered it weighed over 4 lbs. It was very closely set, too closely in fact, for the berries were squeezed together till some of them were in all sorts of shapes. The Vine is growing in an orchard-house, and the fruit was produced without artificial heat.

Class D was for Grapes without Muscat flavour; and the first prize was also taken by Messrs. Lane with *Black Prince*. They were fine, long, black bunches, and of excellent flavour. They, too, were produced in an orchard-house.

A Grape was received from Mr. Denham, gardener to the Duke of Roxburgh at Broxmouth Park, near Dunbar, N.B., for the opinion of the Committee as to whether or not it was the *Muscat of Alexandria*. It appeared from Mr. Denham's letter that this had been exhibited for several years past at the Edinburgh Shows as *Muscat of Alexandria*, and that now an exception had been taken to it—that it was

not Muscat of Alexandria. The bunch and berry certainly have the appearance of Muscat of Alexandria; but the Committee unanimously decided that it was not that variety nor any other form of Muscat—in fact that it was not a Muscat at all.

Mr. B. S. Williams, of Paradise Nursery, Holloway, again showed a bunch of Royal Vineyard Grape, which appears to hang well, being perfectly firm and plump. Mr. McDonald, of Woodstock Park, Inistioige, sent a bunch of true White Tokay, which he anticipated would be the same as the bunch sent by Mr. Denham, but they were not at all similar to each other.

A fine fruit of the true Smooth-leaved Cayenne Pine Apple was sent by Mr. David Thomson, Archerfield, N.B. It was remarkably handsome and firm, and, having been out for a month, refuted the opinion that is held by many—that it will not keep.

George Wilson, Esq., of Gishurst Cottage, sent some magnificent specimens of his orchard-house-grown Apples and Pears. The Melon Apple, Northern Spy, and Yellow Newtown Pippin were very beautiful; and the Pears, which consisted of Benrre Defais, Triomphe de Jodoigne, Chantamel, Joséphine de Malines, and Doyenné Goubault were really wonderful. The fruit grown by Mr. Wilson are certainly the most successful examples of orchard-house culture we have ever seen.

Mr. Lidgard, of Hammersmith, exhibited immense stalks of Celery of the following varieties:—Kimberley's Hero, Williams' Red, Wall's Invincible White, Manchester Red, Coles' Red, and Coles' White. The latter were by far the best flavoured.

WINTERING PLANTS IN A COLD GREENHOUSE —VINE MILDEW.

I HAVE a small glass house fitted into a nook of the house where it gets all the east and south sun, and I am very anxious to keep my plants there all the winter without fire. One end and half the length are against the house, painted white. The front has a division and makes two windows which open. The door opposite one is to the west. There are two shelves in front, two shelves against the house, 3 feet apart, on two sides, and a table one-third of the length. It is built on an arch turned over a dry area which goes partly round the house, which may make it cold but not damp. My plants are chiefly young Geraniums of last autumn and this summer, some fine Fuchsias, all raised by myself, and three small Orange trees. Would frigi domo along the sides keep out the frost? Must I have it over the roof? Must I have a lamp burning at night when frosty? Would any possible contrivance do instead of fire? I should be much obliged for any practical directions.

I could by a piece of iron pipe make it communicate with a glazed verandah into which a drawing-room window opens, and to which a small greenhouse is attached, where there is a fire and a brick flue.

We have a small Grape-house with a border, in which we have Peach and Nectarine trees in pots; they bore very well this year, but one hundred bunches of Grapes were lost from mildew, or whatever the disease is called. What can I do to the Vine to avoid a repetition of the misfortune? and how can I keep out the frost without letting my new little house out of my own hands, as I do all the work of it myself, and it gives me great pleasure and interest?—E. M. W.

[We really wish we could help you effectually, but fear we must merely condole with you. The frigi domo on the sides would be help, but would not hinder a severe frost killing all your plants. That, too, would involve some trouble in taking off and putting it on. We would prefer calico or something of that kind for the roof; and if your front windows are high the calico might be put up in pieces inside, and remain there the most of the winter. Unless the glass-covered verandah were very warm, we do not see what benefit you would derive by bringing an iron pipe from the verandah. We do not know where the position of the furnace for the greenhouse is, but if at all handy you might have a small flat boiler placed over it, and pipes taken from it to your little house, with a tap, a valve, or a plug to turn on heat when you like. The same thing might be done if the fire-

place in the room adjoining is suitable, or if there is a room with a fireplace beneath the arch that forms the floor. That, however, would make you, as respects the fire, dependant on others perhaps, but still leave the giving of heat entirely in your own hands. If the place is at all lofty, a single lamp would not be sufficient unless of a good size, even with the assistance of the frigi domo. A spirit lamp would be best, as if the wick were kept short there would be no smoke. We think that one or two paraffin lamps would be the cheapest and might suit your purpose; but we are not sure whether the products of combustion might not injure your plants—we rather think they would unless there were funnel-shaped vessels of tin suspended over the lamps a few inches above them, and a small pipe from that funnel communicating with the external atmosphere. We would advise you to try one or two of these lamps without any covering of a funnel at first, and notice how much it will raise the temperature. The funnel over the lamp would take off the deleterious matter, and if the pipe were three-quarters of an inch in diameter that would give out the heat that rose through it.

We are now writing with the help of a composite candle that needs no snuffing, with a wire-frame fixed on the candle supporting a shade of paper, green outside and white inside, with a hole of about 2 inches in diameter at the top. The other night we boiled a small saucepan very shortly suspended over that hole. In our bachelor days we have with a similar simple contrivance boiled a small tin teakettle, when we wished for a cheering cup and could not be bothered lighting a fire. With a good-sized lamp we believe we could heat a small tin boiler like a teakettle, and heat the house with two-inch tin pipes taken all round it. Try the lamp first. From experiments with stoves we are well convinced that for small places there is no mode of heating so economical as having the whole of the heating material inside the place to be heated, but then the products of combustion must be allowed to escape.

We may state here for the benefit of young gardeners that myriads of such wire-guards are sold in London for 2d. each and the shades for 1d. each, and may be used until the candle is nearly done. Candles that need no snuffing are a great luxury, and composites about 11d. or 1s. per pound are cheaper and give far more light than tallow candles, but they do not stand carrying. We found, also, recently a valuable hint for getting all the light possible at night from a candle—viz., to use a white or light-coloured cover for the table. We never thought of such a thing before, though we ought to have done so; but just try and see the difference either for reading or writing, and especially if the candle or lamp is shaded. The reflection of light from the light colour of the table, even if the cover be a newspaper, is like the addition of another candle when contrasted with the dark colour. The light colour of the walls will be no particular point in the favour of our correspondent, as it will reflect heat during the day, and in a hot day will be apt to make the place too hot, and in cold nights from not being much heated during the day it will not have so much to radiate back again at night as a darker-coloured wall would have; but then in using a lamp at night little of the heat would be absorbed by the white wall from the atmosphere of the house. As said above we would simply try a paraffin lamp or two first and note how much they raise the temperature.

As to the mildew on the Grapes, very particular directions were given in a late Number, and we can only say, Wash the house thoroughly. Vines and all, and then wash the latter with a paint made of clay, lime, and sulphur; and next season, even if you should use a little fire heat, give plenty of air, leaving even a little on at night from the time the Vines break until the fruit is gathered, and apply flowers of sulphur to the first spot of mildew.—R. F.]

GARDENERS' NAMES FOR FLOWERS.

"G." has misunderstood my meaning, and taken my words in a sense in which I never intended them to be taken. When I said, "I feel sure that well-educated gardeners will say Amen to my remarks," it was not the anecdotes I alluded to, but the position I took on these words,

"I humbly think it would be a retrograde day in horticulture if gardeners' pronunciation of the names of flowers was received by the classically educated as correct;" and, again, more especially on these words, "Surely it is right in this, as in all instances, to endeavour to raise men to the correct standard, rather than sink the standard for the sake of the men." I honoured "D." of Deal, much for refusing to accept as the right pronunciation of a flower one which, as has been proved, was classically wrong, although the name of Mr. Beaton (now, alas! the late) was brought as an argument in its defence.

"G." will also do me the favour to notice, that I spoke of the four cases of very bad pronunciation as being "extreme cases," and, therefore, great exceptions to the regular rule. They had amused me, and I thought would amuse and not offend any reader of THE JOURNAL OF HORTICULTURE. They are perfectly true, and, of course, I did not ask any one to enforce my anecdotes, only my arguments. I can also assure "G." I was not quizzed by my "Johnny Bottle" friend. He was an old man, and once in my own employ; in better days he had been gardener to a near relative of a Peer. He was a very good gardener, though in book matters grievously ignorant. He seemed amused with the name, but spoke it, I am sure, in utter ignorance.

As an instance in an opposite direction, let me give "G." another bit of my experience. I was a few years ago looking over a very good garden with the gardener. It was his own creation out of a piece of flat pasture land. I was delighted to hear his most correct pronunciation of all names. In one instance he, of his own accord, gave me the Greek word correctly pronounced, from which our English name, he said, was derived. On remarking upon this man's wonderfully correct pronunciation to one of his fellow gardeners, he assured me that he was in this respect the envy of all his gardener friends.

Let me add as a word of encouragement to young, very young gardeners, that this man I speak of began life as a servant boy in a village.

In conclusion, let me assure "G." that there lives no man fonder of gardeners than myself. Many an hour's chat do I get with them when I can, and I wish them well, and never more truly was I their friend than when urging them to a correct pronunciation, to which many attain, to which some never attain. "G." will oblige me by noticing my words, "I am writing nothing the least degree offensive to the gardener class"—words by which I meant that my object was to do good.—WILTSHIRE RECTOR.

PORTRAITS OF PLANTS, FLOWERS, AND FRUIT.

STAUROANTHERA GRANDIFOLIA (Large-leaved *Stauranthera*).—*Nat. ord.*, Cyrtandraceæ. *Linn.*, Didymania Angiosperma. Herbaceous stove plant. Native of limestone rocks 2000 feet high, at Moulmein. Flowers white, tinged with purple. Blooms in August. Promises to increase readily from cuttings.—(*Botanical Magazine*, t. 5409.)

GARDENIA OCTOMERA (Eight-parted *Gardenia*).—*Nat. ord.*, Rubiaceæ. *Linn.*, Pentandria Monogynia. Shrubby plant. Native of Fernando Po. Flowers white, tinged with green; lip eight-segmented; tube eight-sided.—(*Ibid.*, t. 5410.)

MICONIA PULVERULENTA (Floccose *Miconia*).—*Nat. ord.*, Melastomaceæ. *Linn.*, Decandria Monogynia. Introduced by Messrs. Veitch & Son. Native of Peru. Leaves beautiful, dark green, tinged with blue, and finely reticulated.—(*Ibid.*, t. 5411.)

WEBBIA PINIFOLIA (Pine-leaved *Webbia*).—*Nat. ord.*, Compositæ (Vernoniaceæ). *Linn.*, Syngenesia æqualis. Cool greenhouse plant. Native of country between Cape Town and Natal. Flowers purple, blooming in August. "Probably will bear the open air in summer, and be grown in clumps, or even as a bedding-out plant."—(*Ibid.*, t. 5412.)

FUGOSIA CUNEIFORMIS (Wedge-leaved *Fugosia*).—*Nat. ord.*, Malvaceæ. *Linn.*, Monadelphia Polyandria. Native of seashore in Dirk Hartog's Island, West Australia. Flowers white, with dark crimson blotch at base.—(*Ibid.*, t. 5413.)

ROSE, MADAME FALCOT.—A yellow Tea variety, deep-coloured and beautiful.—(*Floral Magazine*, pl. 169.)

PETUNIA, MRS. SMITH.—Raised by Messrs. Smith, Dul-

wich. Magenta-coloured, white-margined, and white-centred; very striking.—(*Ibid.*, pl. 170.)

GLADIOLUS, CHARLES DAVIS.—Raised by Mr. Standish, of Ascot and Bagshot. Received a certificate from the Royal Horticultural Society. Scarlet, picked out with purple and white.—(*Ibid.*, pl. 171.)

ASTELMA (GNAPHALIUM) EXIMIUM.—A very brilliant Everlasting from the Cape of Good Hope. Introduced by Messrs. Henderson, Pine Apple Place. Crimson calyx, and orange anthers.—(*Ibid.*, pl. 172.)

DEUTZIA CRENATA FLORE PLENO.—This double-flowered *Deutzia* was introduced by Mr. Fortune from Japan. A dwarf, hardy shrub. Flowers white, tinged with pink.—(*Florist and Pomologist*, ii., 153.)

NECTARINE, VICTORIA.—Raised by Mr. Rivers, by fertilising the *Violette Hâtive* with pollen from the Stanwick. As we said in September, the fruit "has all the merits of the Stanwick, with none of its defects." It is a delicious fruit, in perfection during the middle of September.—(*Ibid.*, 160.)

LABOUR AND LABOURERS IN IRELAND.

In answer to several inquiries, I would say that circumstances have led me to keep back in the meantime, as something good in the background, the account of some more places in Ireland I saw on my hurried visit. The manner in which these sketches have been received has been to me a source of pleasure not unminged with sorrow, the sorrow being owing to something like an undercurrent of belief, that the pictures of improvement and comfort were too rose-tinted to be real. Some friends tell me I should have gone to this and to that place, and then I should not have failed to have seen misery, idleness, starvation, wretchedness, and hovels not fit for pigs to live in. Well, this may be all too true, but I hope it will have disappeared before I have the chance of having another tour in Ireland. Perhaps I was fortunate in seeing so much of industry and comfort, and I spoke as I saw—not but that I witnessed some miserable dwellings, and a few shivering workmen who were vainly "asking for leave to toil;" but, unfortunately, I had seen more than enough of such misery in Scotland and England too, and too often unaccompanied with that sympathy and willingness to help each other which has long been a prominent feature among the poorest in Ireland. That labourers in Ireland could be as intelligently active as their brethren in England, when anything like similar inducements were presented to them, was, however, the greatest of all anomalies. One friend insinuated that what was said of the working man at Straffan must have been all a myth borrowed from Cloudland—in fact, said as much that the place could only have an "airy habitation" in my own imagination! Strange, indeed, that the industrious Irishman in England could be nothing but a tattered, lazy, misworker in his own land, with children crowding around him demanding his every energy! True, I never should imagine that the man who squatted in a chimneyless hut, and worked his long dreary hours for from 6d. to 9d. a-day, could even be expected to put forth the energy of the man who was fairly paid for his labour. On this account I was one of those that delighted in emigration as the chief means for raising the wages of the working man that stayed at home, and yet making work cheaper for the landlord and the farmer, by the superior quality and greater quantity of the work performed. There is no use in mincing the question. Where there are not the means for building up bone and muscle, there can be no energy for continuous labour. Low wages are, therefore, generally synonymous with dear high-priced work. Emigration, which in moderation would thus have been a blessing, if continued long at its present rate will turn a blessing into a curse, by depriving the land of its chief labour power. It is high time that those who for their own purposes have traded in Irish discontent, and the owners and livers by the land, should arouse themselves and present inducements to their labouring brethren to remain at home. The Marquis of Waterford at a large agricultural meeting stated, "That large farmers should encourage more field labour. He would be happy to give cottages for labourers, if his tenants would give them work." Let such work be judiciously given and remunerated as it ought to be, and then, but then only, will

emigration be stayed, and the descriptions of laziness, idleness, and carelessness become tales of the times long ago.

As in this work of gardening the opinions of gardeners must ever be interesting I send the following letter, cut out of the *Dublin Evening Post*, of October 31st, as tending to show that my statements were not at all out of the way.—R. F.

"Your report of the Portlaw Farming Society is a hopeful sign of better things for the labourer. The happy union of Portlaw and Curraghmore in the interest of labour is a promising subject. The Marquis of Waterford occupies a high position, and his opinions and acts are closely watched outside the limits of his own large property.

"In your report of the Portlaw meeting, the Marquis hardly does justice to the workmen of the South of Ireland. In speaking of Flax-culture, the Marquis says:—'The culture of Flax required skilled labour, and the great mass of the people in the South of Ireland were not in that high state of perfection, as labourers, that would warrant a landlord or any one interested in the prosperity of the soil, to say to the tenant, "Embark in Flax 50 acres." All are interested in the soil in Ireland, it is the taste and genius of the people, and it is a lamentable failure if the labourers are not equal to the operations necessary to bring a crop to maturity, which crop is a common crop in a less favoured part of the country.

"The farming and manufactures of Meers, Malcolmson, &c., also their ship-building yard at Waterford, is strong evidence there is no lack of good workmen around Waterford. I think it a duty to offer you publicly my own experience of labour in this part of Ireland: For five years I have had a great number of labourers under my charge, and I unhesitatingly assert that they are as obedient, as regular, and perform common operations of work as well as any labourers in Great Britain. I have seen with admiration what Mr. Horn has done with untrained workmen in building ships. I am not aware that there or here the workmen are over the average of their class. There may be some advantage here, as Colonel Tighe is well known to be a most kind and liberal employer, and it deserves to be told that in the past three years Colonel Tighe and his lady have spent large sums of money on extra labour, *truly to give employment*. The work executed is open to the public and speaks more to the credit of the workmen than any form of words I can use.

"Why, Sir, it is no use—nothing can be done with Irish labourers; is a cry without grounds—it is idle—a wretched excuse for doing nothing; it is lack of enterprise and sincerity. Not the labourer that is to blame; he works—may, begs for work—and works, under all the disadvantages that well can be. I apprehend there is quite as much want of capacity in those who conduct the workmen as there is want of ability in the labourers to perform reasonable duties. Nor is there that want of taste and want of order so much laid against the Irish tenant. See the noble mansion of Adair Manor, and ask the Earl of Lunnoven who hewed that excellent stone and woodwork. Or go and see the cottages built by Mr. Napier, of Loughcrew—Mr. Herbert, of Muckross—or those about this place, and you will find how readily the labourer improves.—I am, Sir, your obedient servant, CHARLES McDONALD, *Woodstock*."

GREENHOUSE TROPEOLUMS.

ALL are agreed as to the desirability of variety, especially of colour, in the decoration of greenhouses and conservatories; and this object should be aimed at as much in winter as summer—indeed to my mind more so at the former than the latter season, for we have in winter fewer flowering plants to choose from. I read lately of a lady complaining of the monotonous appearance of her flower-borders—green and white, white and green, having become wearisome. Many people of small means make a similar complaint as regards their greenhouses, which are much less attractive than they might and ought to be.

Tropeolums are plants of easy management, and when once a person understands their mode of treatment they can be so managed as to add much to the decorative effect of the greenhouse. Where I first became acquainted with this class of plants they were held in high estimation, and great care was bestowed particularly in propagating them. This was done by taking off the young and tender points of their growths, inserting them in pure white sand, kept moist, under bell-glasses, where a moderate bottom heat could be maintained. It required a watchful eye to make them succeed well; and when they did form their small tubers it was some years before they could, from their size and strength, give much flower, however desirable it was to have them blooming in winter, with their singular yet very pretty colours.

About fourteen years ago I went to live in a part of the country where a neighbour was skilled in growing Tropeolums, and I will now very briefly detail his practice, remarking that, from my friend's success in their cultivation, I was induced to try the same mode. It is now more than ten years ago, and I have not yet had any reason to abandon this line of treatment.

Supposing that we have four ordinary-sized tubers or roots of *tricolor* or *Jarrattii*, that we wish to grow each tuber in a separate pot, and are likewise desirous of increasing

them whilst having as many flowers upon them as they can produce, proceed as follows: Take some good fresh turfy soil, with a little fibry peat chopped pretty small, and a good portion of silver sand, all well mixed together, so as to be a nice fibry mixture, such as will not be too close or become sodden. Having the compost all ready, the next proceeding is to take four pots about 8 or 9 inches in diameter at the top, to drain them well, placing moss or some similar material over the drainage, and then to fill the pot rather more than half full of the compost. Place the root into this, having the crown of the tuber all but covered, so that you can see when it begins to grow. A strong root will often give several shoots or growths. Let them grow on. When they are 6 or 8 inches long put in the stake or wire trellis on which the plant is to grow, as, if delayed longer, the growths of the plant might be injured in putting in the trellis, owing to their being covered with soil. The trellis having been put in, the next proceeding is to lay the young growth or growths across the soil in the pots, carefully covering them over with the same kind of soil; and as they grow go on turning them from side to side in the pot, gradually letting them rise higher to the top of the pot, and of course adding more soil each time. When done in this way, carefully bending them where there is a joint in the slender stem, they will generally form a little bulb at every joint.

Now to give an outline of how my friend grew his pots of Tropeolums. He generally had his in pots from 12 to 16 inches in diameter, and had the compost much the same as that which I have described. Into the large pots he often placed an inverted three-inch pot at the bottom, and filled in an inch thick of potsherds. Over this he placed some moss, and then filled the pots three parts full or rather more before he put in the tubers. Into the largest pots he would put six or eight good-sized roots, just covering them over, and placing them in a circle about an inch from the top. After they were started and 6 or 8 inches long, he put in the top of a compactly-grown Larch tree, perhaps from 3½ to 4½ feet high, or the top of a Holly tree from which all the leaves had been carefully removed, and as the plants grew he covered them over with the same kind of compost, still inclining them towards the stem of the Larch tree on which they were to grow. He allowed them to ramble all over it; and in the course of time it had the appearance of a cone of 2½ or 3 feet wide at the base and 4 feet or more high from the pot. Trained in this way the plants had a charming effect in a conservatory during the spring months, and afforded a nice contrast when placed beside some of the white Azaleas on the one side and a nicely bloomed Rhododendron on the other, backed up with a Camellia, or even when placed alone upon the floor of a conservatory, where the pot could be seen and admired on every side.—G. Dawson.

TRENTHAM.

(Continued from page 376.)

At the south-west corner of the main garden, and at the west end of the ribbon borders, is one of the most elegant conservatories of the day.

It is ridge-and-furrow-roofed, 11 feet in height, fully 70 feet in breadth, and 100 feet in length, as far as could be judged by pacing it. We have always understood that this was the first house in which the ridge-and-furrow roof was used to cover a large space of ground without any great altitude of roof, and so preventing the drawing of the plants, and doing away with any necessity for stages and platforms. The width of the pathways, and the neat stone edgings fringed with Lycopods, &c., conjured-up ideas of ease and gracefulness: whilst the somewhat stiff trimness of the massive specimens in the beds and tubs, was relieved by the wild flaunting luxuriance of the dangling creepers and climbers. Among the most prominent of these were fine-foliaged Acacias, different Passifloras, Tacsonia mollissima, Bignonia jasminoides, and the beautiful crimson *B. Chivere*, *Ipomaea Learii* in fine condition, the never-ceasing-flowering *Habrothamnus elegans*, the light blue *Plumbago capensis*, and a huge mass of the *Cestrum aurantiacum*, which produces long racemes of its golden flowers

all the winter. It would be endless to enumerate the fine plants in the beds of this house, mostly trained less or more in the pyramidal form, which gives more room for the streamers of climbers and the baskets of creepers suspended chiefly over the pathways. The house is always kept gay by fresh introductions during the season. In the end of August we were most struck with fine-flowered *Fuchsias*; large *Brugmansias*; a fine plant of *Luculia gratissima* covered with buds; a huge barrel-shaped plant, reaching nearly to the roof, of *Camellia reticulata*, well supplied with large buds; very large plants, in the highest luxuriance, of other *Camellias* and *Azaleas*, less or more in the pyramidal shape; fine masses of *Hedychium*, as *Gardnerianum* and the sweet white-flowered *coronarium*; a good plant of *Rhododendron Dalhousianum* with well-swelled flower-buds; and at the north corner of the west front, inside, was a strong plant of the New Zealand Flax, with a seat on the pathway behind it, from whence you could see any one crossing the iron bridge over the river, and be yourself concealed by the thick foliage of the Flax, possessing as it does a luxuriance we might look for in vain out of doors in the warmest parts of these islands, though it thrives pretty well in some parts of the south of Ireland.

The west front of this conservatory is separated from the river by gravel and a sloping bank of turf delightfully green; and a little farther north, opposite the foot-bridge, is a large parallelogram of gravel backed by evergreens; and on that parallelogram are inscribed in broad letters of Box the names of the four sisters of the present Duke, with "*Great memoria*" beneath them. On our previous visit to Trethurton Mr. Fleming told us he could use salt water for destroying weeds inside and round these letters without injuring the Box, though for ourselves we always found Box very easily injured by salt in any shape. Whether and how salt is now applied we failed to inquire, but all the walks were in excellent condition.

Close to the north side of this fine conservatory are elegant gates that form, we presume, the chief entrance to the kitchen garden from the mansion, these gates being in a line with the arched Pear-walk running from east to west which we have already noticed. At the back of the conservatory is an open square of gravel, as if for setting plants on in summer if desirable. The back of the house was clothed with Ivy, but beautifully draped with long streamers of *Honeysuckle* and *Ayrshire* and other climbing *Roses* allowed to dangle naturally, with little or no appearance of training to molest them. Trina training would have spoiled their beauty. It would be well if gardeners could be persuaded at times to "let well alone."

We now pass the gardener's house again, cross the roadway and the rustic bridge over a brook that falls into the Trent, and find ourselves in the village of houses and pits on the north side of this main entrance. Here too we are, as in the principal division, presented with the same ideas of the ornamental. Here is the background of shrubbery all round, raised beds skirted with Ivy and *Cotoneaster* alternately, filled with *Geraniums*, *Humeas*, &c., and in the front of the large stove-range is a beautiful flower garden, the beds edged with Thrift, and the colours chiefly belted and well contrasted.

We first come to a very long house called the Brook-house, and almost entirely filled with fine plants of *Azaleas*, as it is found useless to put them out of doors in summer. Then opposite this at right angles is another long range with ridge-and-furrow roofs, the first a greenhouse with a stage, walk along the front, and Tea *Roses* against the back wall. These *Roses* are exposed to the full air, and are kept rather dry in autumn so as to harden the wood, and then there are plenty of fine *Roses* all the winter and spring in the usual greenhouse temperature. The stage in this house is also cleverly managed, the end and the front, as high or higher than the front shelf, are covered by a trellis filled with *Camellias*, *Acacias*, and *Scarlet Geraniums*.

Next and much wider is the moist stove or tropical aquarium conservatory, there being a tank supplied with hot water immediately in front of the entrance. The back wall is formed into a rough rockery for Ferns, Mosses, &c. The plants over the aquarium and elsewhere in pots were chiefly distinguished for the beauty of their foliage, as *Cyanophyllum magnificum*, *Alocasia metallica*, very fine

plants of varieties of *Croton*, *Dracenas*, *Marantas*, *Musas*, &c., and fine specimens of the beautiful finer kinds of *Caladium*. We presume the *Nymphaeas* and other water plants were chiefly in a state of rest. The front curb of this house is fitted with a shallow pan, and for the whole width it was a dense green mass of the dwarf *Lycopodium apodum* or *densum*. The beauty of these plants as specimens was more than rivalled with the wild grandeur of the flouting creepers above. For natural magnificence (for the art to effect it was completely hidden), we have seen nothing to compare with it except the middle division of the stove of Mr. Bewley near Dublin. In this latter case, however, the striking effect was produced entirely by the rich-leaved streamers of the *Cissus discolor*. Here this plant was also in its glory; but mingled, shaded, and contrasted, with the foliage and flowers of *Stephanotis floribunda*, *Ipomoea Horsfallii*, &c., *Passiflora princeps* and *quadrangularis*, &c., *Allamanda cathartica*, *Bignonia venusta*, &c. So wild, mingled, and luxuriant are these and others that it requires close examination to perceive whence the stems come from, and to note that all are under control. The beauty of these climbers in summer depends greatly on the treatment they receive in autumn and spring. In September the tank is dried, plants requiring a moister atmosphere are removed elsewhere, and the house, as a whole, is kept drier and warm, but with more air to harden and ripen the shoots of these climbers, which are gradually pruned pretty close home in winter when more light is wanted for the plants in the house. This causes the climbers not only to break strongly and healthily, but with shoots that will be smothered with flowers. At the end of this house is another greenhouse filled with fine close-trained plants of the later kinds of *Azaleas*, and here too the back wall is covered with Tea *Roses* treated as already detailed.

Amongst other things we must state that we looked into a beautiful span-house devoted chiefly to *Heaths*, *Epancrises*, and other New Holland plants, the path being sunk in the middle of the house and the stage on each side of it; then into a span stove-house, where, among other fine things, were a great many of the most beautiful plants of *Crotons* plunged in a hotbed after being potted afresh; then into another long span-roofed stove, small as to width, but not small as to length, filled with *Euphorbias*, *Gesneras*, &c., and the roof a picture from end to end with *Hexacentris mysorensis* and *Thunbergia laurifolia*, the latter in very fine condition. Then we looked into a pit filled with softwooded stove plants of the most free-flowering kinds, as *Poinsettias*, *Justicias*, *Gesneras*, &c., that had not long been underpotted, for these plants are wanted in such quantity for house-decoration and to go into vases, basins, &c., that after they have been pretty well grown it is often necessary to shake away a good portion of the soil, to underpot them, and have them well established again before packing them thickly in vases, &c. Many vases and zinc pans are filled and kept ready for moving into the finer receptacles designed for them. We also noticed whole beds of *Linum monogynum* in smallish pits, *Cinerarias*, *Primulas*, *Crassulas*, *Calceolarias*, for everything is made to serve its purpose. Were we to tell of *Cucumber-houses* in all stages, *Melons* in houses and pits in all stages, pits and houses filled with beautiful Vines in pots, ditto with Figs, and all the rest of it, and all in small pots for their size, telling that they had something to nourish them besides the earth you saw at the surface, we should want a Number for the express purpose.

One secret we did find out in our solitary ramble in the morning—a large shed filled with mellow cowdung and a huge heap of boiled bones beside it, and the men were cutting the dung with a gusto as if they knew its value. A second secret was a huge mound of bright-looking coals at a price which we in the south must not yet think about, and it is always well to keep down every rising of that nasty spirit called envy. A third secret, we did not find out, because we forgot to make inquiries about it, though we had plenty of reminder too in seeing a vapoury smoke issue from a black funnel among some trees, and not a wreath over all these houses and pits. The secret, the great secret which we ought to have found out, is how from all these houses and furnaces the smoke is conveyed by tunnel, and in low ground too, to this one concealed funnel as a chimney top.

The beds were beautifully filled, and the garden as a whole a delightful spot, and quite large enough for the majority of our readers.

R. FISH.

(To be continued.)

A PERSONAL NARRATIVE OF POISONING BY A NOXIOUS FUNGUS.

(Communicated to the Society of Amateur Botanists.)

FIG. 2

FIG. 1.

ORD. 1.—AGARICINI.

SERIES 2, HYPOBODII. SUB-GENUS 12, ENTOLOMA.

215. *Agaricus* (*Entoloma*) *fertilis*.

Pileus smooth, pulverulento-squamulose, dry, fleshy, obtuse; stem fibrillose, sub-squamulose, somewhat bulbous; gills flesh-coloured, adnexed. In woods. Smell like that of fresh meal. Pileus 4 inches or more across, of a pinkish-buff.—(*Berkeley's British Fungology*.)

At the request of the President of this Society I beg to lay before the Meeting a few particulars regarding the poisoning of myself and family by a dangerous fungus found in woods, and scientifically known as "*Agaricus fertilis*."

The single specimen eaten was gathered in Bishop's Wood at the close of September. I was there, searching for fungi in general, with my friend and patron, Mr. M. C. Cooke, when the specimens of *Agaricus fertilis* presented themselves. I took one home, the smaller one, and Mr. Cooke took the larger.

Having constantly eaten a variety of species of fungi without unpleasant results, I was not sufficiently cautious over this one, and the consequences that followed the consumption of this specimen were entirely owing to my own carelessness in not comparing it carefully with published descriptions. I had the same day seen a drawing of *Agaricus giganteus*, and I thought the species gathered was certainly that, but I did not refer to Berkeley for a minute description, or I should have seen my error at once, as I did when too late. After breakfast I most foolishly prepared

the upper part of it for luncheon, throwing away the stem and even part of the pileus or top.

At the time of eating it I thought it was all right, as there was nothing at all unpleasant or acrid in the taste of it either when raw or cooked. But I ought to say, in justice to the fungus, that I kept it under a propagating-glass for two days after it was gathered.

The fungus cooked in first-class style with butter, salt, &c., in the recognised way, I proceeded to test its gastronomic qualities, which I found to be of a high order. There was very little of it when cooked—not more than half an ounce at most: of this I ate, perhaps, one-half or a quarter of an ounce. Mrs. Smith, who is an amateur fungologist, ate two or three very small pieces, and one of my children, two years old, came round the table, and took one or perhaps two very small pieces off the plate. As I thought it was all right I did not prevent her. So the cloth was cleared, and all appeared well.

I shall now proceed to give an account of the effects of this particular species; and although it is not specified in Berkeley as poisonous or suspicious, it will be seen by the sequel to be one of the most violent and dangerous in its effects of the whole tribe.

It so happened that morning that I had business in the city, a very unusual thing for me, so I will narrate my own symptoms and experiences first, apart from my family. I had to start by a train on the North London railway for Fenchurch Street about a quarter of an hour after I partook of the fungus; and I can well remember that while waiting for the train, close by my own home, and within twenty minutes of eating the species of fungus, I was overtaken by a strange, nervous, gloomy, low-spirited feeling that was quite new to me. I, however, thought nothing of the fungus. By the time I reached Fenchurch Street this feeling had considerably increased, accompanied by a dull headache; but I still thought nothing of the fungus. My business took me through Billiter Street on my way to Devonshire Square, and as I passed some of the warehouses I noticed some men loading and unloading certain goods that gave forth a most powerful and oppressive odour. I had no sooner got out of Billiter Street than I found my headache much worse, accompanied by an unpleasant swimming sensation, while two or three sharp pains shot through my stomach. By some strange process of reasoning I now attributed my indisposition to the stench in Billiter Street, an opinion I retained till I got home. I soon transacted my business in Devonshire Square (it only engaged me a minute), and then I made the best of my way back to Fenchurch Street, my illness increasing with every step. Still the fungus never entered my mind. When I got to the station my head was aching and my brain swimming to such an extent that I could hardly walk; while everything in the station appeared to be moving with death-like stillness, either from side to side, up and down, or round and round. This is no exaggeration whatever, and worse is to come yet; and what appears so remarkable to me is that such terrible effects were produced by eating such a small quantity; one would think if five or six had been eaten instead of one (minus stalk and part of top), that instant death would have ensued. I will, however, continue my account. I staggered into a carriage, and reached home in twenty minutes, so ill that I could hardly place one foot before the other, with the overpowering feeling of sickness increased to a degree that was unbearable, although I could not be sick. I knocked at my door with the determination of going to bed directly I got in, sending instantly for the doctor, and making up my mind for a severe attack of brain or some other fever; and I had never all this time thought about the fungus we had for luncheon.

I must now for a few minutes revert to my little child and her mother. On knocking at my door the first thing that called my attention was the delay in answering the knocks. The door was opened, however, in a few minutes by Mrs. Smith, who could hardly walk to the door, and could not speak for crying. I will here make another statement that may appear somewhat apart from the subject. We received a letter from the country two or three days before this occurrence, stating that a brother of Mrs. Smith's lay apparently dying after a serious illness, and no hopes were given of his recovery. On seeing Mrs. Smith thus distressed I

immediately thought her brother was dead (I never thought of the fungus), and after telling her I was certainly dying too, I began to say a word or two expressive of my sorrow for her loss; but before I could say many words she let me know that she had been worse than I had been: that the little child was downstairs in the arms of a neighbour, apparently in the last stage of existence (as Mrs. Smith was too prostrated to hold her own child), while the servant was sent out for the doctor. When I saw how matters stood my illness to a certain extent seemed to pass away, and on the emergency of the occasion, ill as I was, I left home to get immediate medical assistance, which I was fortunate enough to procure pretty readily.

It appeared, directly I left home Mrs. Smith took our little child out for a short walk, and bought a slate and pencil; but the mother had no sooner left the shop (about twenty minutes or half an hour after luncheon), than the same swimming of the head came over her that attacked me; and what with headache and sickness she could hardly reach home with her child in her arms. Directly she got into the house the little girl suddenly fell sick, and the sickness speedily became so violent that by the time I returned she was perfectly prostrated.

On the first day Mrs. Smith and the little girl were much the worst of the three; but after the first and second days I was worse than all. The effect on my wife was utter prostration by the vomiting and nausea, and a feeling of loathing everything eatable that was brought to her notice. Her vital powers were so greatly reduced at the end of the first day that she had no strength to be sick, and brandy had to be freely administered.

The little child was certainly the most affected, and if the medical attendance had been delayed I am sure she could not have survived more than one or two hours. She was in a deep stupor or sleep, with her eyes wide open and fixed, her fingers occasionally clutched convulsively, and mouth twitching. At intervals of about five or ten minutes a fit of sickness appeared to come over her, by the heaving of her chest and stomach; but after the first hour she had not strength enough left to be sick.

The doctor administered two emetics and other medicine to her, and found it necessary to attend her three times a-day for the first two days, and remained in attendance nearly a week. The little child remained in the stupor for twenty hours, and after this time gradually recovered and regained strength. This ends the notice of the child.

Mrs. Smith, after two or three days' medical attendance, gradually got all right again; but this was not the case with me. I shall now give a few details of the latter part of my own illness, and conclude the paper.

I certainly ate the lion's share of the fungus—say a quarter of an ounce. The feeling of sickness and nausea did not leave me for a fortnight, and for three or four days I ate comparatively nothing and drank nothing but coffee and milk. In my case, on the first day it caused swimming of the brain to an alarming degree, the most distressing headache, and vomiting, and excessive purging. I note the purging particularly, as I was the only one of the three so affected: this lasted for four or five days, accompanied by a feeling of loathing, sickness, and lassitude. At nine in the evening of the first day a heavy drowsiness came over me, and I fell into a deep sleep for twelve hours. Racked and harassed by dreams, in which fungi, and particularly poisonous fungi, always played a prominent part, advancing and retreating, increasing in size and diminishing in an endless maze; but always fungi—poisoned by fungi; dead poisoned children—dead fathers and mothers, &c.

This sleepiness was shared by my family, but not to such an extreme degree; for, after my twelve hours' sleep of the first night, I came down stairs and thought I could do a little work; but I fell into an uneasy but deep sleep in my chair at ten o'clock, and did not wake till two, making four hours more sleep. I took hardly anything to eat the rest of the day, and at five o'clock fell asleep again, and slept till nine the next morning, and had a better night.

I noticed on the second night that all the joints of my legs and feet were quite stiff, and I could not move them without inconvenience and pain; but in the course of a day or two this gradually passed off. For three or four nights I also noticed that when the drowsiness came on, a swim-

ming of the head and sick feelings accompanied it; but it all gradually passed away during ten days or a fortnight.

I certainly received a most severe lesson with my experience, and shall be careful in the future when I gather a species new to me to determine the species with certainty before I cook them.

In my short paper on the growth of "*Phallus impudicus*" I stated that my rabbits ate the porous stem quite readily; so when I knew the effects of *Agricus fertilis* on the human system I thought I would try it on rabbit economy.

I recovered the stem I had previously thrown away, and placed it before the rabbits for their approval, but they refused it with disgust, although the taste was not unpleasant. I think, therefore, we may say that should the choice in future lay between *Agricus fertilis* and *Phallus impudicus*, the latter should be preferred for culinary purposes.—W. G. SMITH.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE heavy autumn rains probably retarded the progress of trenching and other ground operations: the present weather offers abundant opportunity for continuing such work. The garden by this time should be freed from all unnecessary and exhausted vegetable matter, and put generally in a clean and orderly state. *Asparagus*, the beds if not already attended to, should be manured and dressed for the winter, and a portion taken up for forcing purposes. *Endive*, cover the plants with a slate or tile laid on each, and close the whole over with dry leaves, finishing with some stable-litter; in this manner they will blanch well, and be fit for use throughout the winter. A very considerable store of leaves should also be collected for lining hotbeds, Sea-kale covering, &c. *Herbals*, if they are not yet cleaned and done up for the winter, they should be attended to without delay. A slight coat of very rotten dung should be laid on them, for the double purpose of protecting the roots from severe frost, and to enrich the soil. *Lettuce*, the Cabbage varieties planted in frames and intended for winter use, will not require much air if the soil is light and dry; should they need a little water, give it to each plant separately from a watering-pot without a rose. Never expose the plants to heavy rains. *Peas*, a sowing of these and also Broad Beans should be made at once, choosing the most sheltered piece of ground at command, and which should also be of a light dry nature. Use an early hardy sort, such as the Daniel O'Rourke Pea, and Mazagan Beans. *Rhubarb*, the forcing of this and also Sea-kale, must now be attended to, and provided there is a good stock of strong roots, a supply of these will be easily kept up. Where there is room to spare in the Mushroom-house, this forms a very suitable and convenient place for forcing them. The roots to be placed on a slight bed of warm dung, filling up the spaces between them with old tan, or the soil and manure, mixed, from an old Mushroom-bed, giving a good watering to wash it in amongst the roots. The bottom heat should not be allowed to exceed 70°, as too much heat is not favourable to securing strong growth, and, except for the first crop, it may be dispensed with altogether. Clear up all decaying leaves, and stir the surface of the soil on dry days among growing crops, as Cabbages, Spinach, &c.; also, get all vacant ground manured and ridged-up as quickly as possible, in order that it may be exposed to the influence of the winter.

FLOWER GARDEN.

A fortnight's fine weather in November, while it seems to prolong the autumn by permitting us the enjoyment of the fading glories of vegetation, also affords us the opportunity of proceeding with the various important operations connected with the garden; finer weather could not be desired for planting evergreens, &c., than we have had lately. This sort of work should be in active progress. The clearance of all decaying matters from the beds and borders should be unremittently followed up, the remaining leaves will soon be down, when a final clearing may be made throughout the shrubberies for the season. A little care may preserve *Chrysanthemums* for some time, especially those trained against a wall. The simple protection of a mat will turn aside the excess of frost likely to injure them. Take up

and store Dahlias, Marvel of Peru, *Salvia patens*, if not already done, and finish planting bulbs. The best place to keep Dahlias is under the stage in the greenhouse. Where this convenience is not to be had, perhaps the next best way to preserve the tubers is in a cool cellar; at all events they must be kept from damp. Beds intended for *Ranunculus* in February, to be turned over, and any fresh compost or soil will be better added now. Choice plants in the borders, intended to be protected for the winter by slightly covering the roots, &c., should be seen to at once. Roses of the tender kinds, especially standards, to have a bunch of dry moss, or a wisp of hay or straw, or some dried Fern bound round the head, and the whole well fastened to a stake.

FRUIT GARDEN.

Fig trees must now have some dry fern or spruce boughs nailed over them to prevent injury from severe frost. Some prefer gathering the shoots into several bundles after being unnailed, and then wrapping mats round them. Prune and nail Vines, and other fruit trees as before recommended. Brush the leaves off the Peach and Nectarine trees with a new birch broom, and unnailed the small shoots. The planting of young fruit trees, and transplanting or raising those of larger growth, to be vigorously prosecuted: the season is very favourable, and the earlier these operations are performed, the greater is the chance of success.

GREENHOUSE AND CONSERVATORY.

Sunshine and clear skies are not the traditional enjoyments of November in England. The inmates of these structures usually suffer from the diminished light and the fogs and mists of this dull, dreary month. The frosty nights will render a recourse to fire absolutely necessary, while the succeeding bright days will allow the advantage of a free circulation of fresh and wholesome air. Regularly remove all dead leaves, and prevent the spread of moss in all situations. Creepers to be closely tied that they may interfere as little as possible with the action of light on the plants. The bulbs of the Japan Lilies to be shaken out of their pots, and to be repotted in half good fibrous loam, and half peat soil, or decomposed leaf mould, as a substitute for peat, with a small portion of silver sand. As the bulbs, when making their spring growth, emit roots for 2 or 3 inches up the stem, they will now require to be planted that depth from the surface of the pot, and to be earthed-up with the compost in the spring. All plants in these structures to be kept rather dry, giving whatever water may be necessary on the mornings of fine days, so that the superfluous moisture may be removed before the evening. *Pelargoniums*, herbaceous *Calceolarias*, *Cinerarias*, &c., for late blooming to be kept cool and dry, and should not be allowed to suffer for want of pot-room. Plants intended to flower early should be encouraged with a gentle heat, keeping them near the glass, and admitting air at every favourable opportunity.

PITS AND FRAMES.

Abundance of air to be continued as long as possible, avoiding, however, the least wet. As long as the thermometer stands above 32°, give air. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

WEATHER, with the exception of Lord Mayor's-day, which was fine throughout, windy, wet, with frosty mornings, which have at length settled our Dahlias. We have some Dwarf Kidney Beans, sown in July under protection, and which are still, on the whole, fair, without any artificial heat; but we notice that the elder pods are becoming a little hollow and do not crack easily. For a number of years we have generally wanted a good supply about the beginning of this month, and this sowing used to give us a good yield without any help from hot beds or hot pits, &c. We may keep them to the end of the month, but we do not think they will be so crisp as they ought to be. A Dwarf Kidney Bean is one of those things that are rather the better for being forced. To succeed those under protection we used to sow in pots in the end of August out of doors, and place them under glass where a little heat could be given them by the end of September if needed. To keep up

a succession sow now. We generally, to save room, sow in boxes, say 3 feet by 1 foot and 6 inches deep, as little space is occupied until the shoots begin to come, when the plants may be turned out in a bed or in pots in warm soil. Heated soil is of importance. The replanting causes the plants to bear sooner. Rich light soil should at this season be used, and syringing with warm clear soot water in a sunny day is good for keeping the foliage all right.

Gathered all the remainder of Chilis and Capsicums, and were sorry to throw away the plants, as they would have produced a heavy crop early next season if we could have kept them over the winter, but it was of no use thinking to find room for them. The tops of the plants and all the greenest fruit will be capital for mixing with tobacco or laurel leaves for smoking insects when they show themselves. Sowed on a slight bedded Radishes and a sprinkling of Lettuce seeds in case anything happens to those plants out of doors. Filled a frame with nice Lettuce rather more than half grown. Took up a lot of full-grown plants and put them under the thatched roof where our first out-of-door Mushroom-bed was. In severe frost a little litter or dry hay may be laid over them. Covered up a piece more Endive, curled and plain, with beads, slates, pieces of old tan, and then a slight covering with leaves, to give a large supply in a fortnight. Took up also a good lot of fine-grown plants with good balls from a bank, and turned them in close together on a border made into an earth pit, watering them at the bottom and putting dry earth on the top. Here we can shelter from much wet, protect from frost, give full air when fine, and just cover up a little piece for blanching as needed. The great enemy in such a place has been mice—both house and field or grass mice. Who will tell how to destroy whole flocks of the latter in the best manner without exposing any other animals to risk from poison?

Took up as many roots of *Asparagus* as filled one light of a frame closely packed, and will fill the other light in a week or two as the ground gets drier. Cut down the *Asparagus* stems after gathering a lot of seed, chopping it at two or three times with an old scythe, as that and everything else that will heat must go into the fermenting-heap. We must use the whole of the beds in the flower garden for the same purpose. Such things as *Calceolaria amplexicaulis*, *Salvia fulgens*, &c., are all the better of being thus chopped over, so that the length shall not exceed a foot. All these *Verbenas*, &c., from beds, when mixed with leaves, sweepings of grass, and a little dung, make a very nice fermenting-heap. Perhaps the least valuable for this purpose are frosted Dahlias, but even they are better than nothing. We depend much on a few tree leaves, and we wish now we had collected a few before the late tremendous winds, as in our high place they have mostly been carried away to enrich the farm fields in the valleys. It is important, however, that the stems of these flowering-plants, *Asparagus*, &c., should not be too long. We recollect when a heap was turned and some Holly-hock-stems, &c., had been used rather long, a stout young chap grumbling sadly, said, "That it was only to annoy he." As soon as the frosty nights showed themselves, we removed a number of barrowloads of Cauliflowers with heads nice and compact, about the size of a good fist, and placed them in the shed where we had put some the other week, and also the Lettuces mentioned above. We did not trouble much with balls in their case, but stuck the roots in the dung of the Mushroom-beds, watered them, and then trod the material of the bed firmly about them, and leaving only a few of the top leaves, as these will protect from frost. These we had partly protected previously by placing some of their own larger leaves over them; but after such rains very little frost injures them. A younger lot we will try and lift ere long with balls, and place under the protection of old sashes or straw covers. Wood covers, moveable, or that could be tilted-up on fine days, would be the best. Pricked-out also a lot of young Cauliflowers in a frame, in case those under hand-lights, &c., should fail. Put a few scores also in small pots. They came after repotting very early last season.

FRUIT GARDEN.

The ground has been too wet to proceed with pruning. We had some straw ready to lay over Strawberry pots if the weather should be at all severe, as we have not yet put them under protection, but will try and make room for

them in the orchard-house, or under old sashes or moveable covers. When plunged in leaves laid on the surface, and a few leaves over the pots, they will stand almost any frost if the soil is dryish. Their own leaves will also help them. For this purpose we never take off a leaf until we begin to put them in for forcing. Long practice has convinced us that if the pots are very wet and much frosted in winter, the flower-buds are apt to suffer. Packed a lot more on their sides against the back wall of a pit, laying the first layer on their broadsides and three to six layers above them, which will tend to keep them dry and also arrest growth, both of which are of importance before commencing to force. We used to build them up in this way, packed in ashes, and a board along the top row, before we could obtain any other protection for them. Straw hurdles set in front of them in frosty weather kept the frost from them. In this way we seldom had any injured by mice, but we always lose a few in hard winters by these vermin, when we set the pots on the level, with a few leaves between them, whenever the winter is more than usually severe. We prefer a wall for such storing when such can be had, but we have had the plants do very well when the pots were fired in a bed of ashes, just like a small span-roofed house or a ridge Mushroom-bed. Thus, set off a bed—say 1 yard in width—with a layer of ashes at bottom, lay down a row of pots all round with the plants to the outside, fill up the space behind the pots with ashes made firm, and bring the ashes forward to the rim of the pots, making all level and firm, and seeing that the ashes below the bottom end of the pot are sufficiently high that the top of the pot, when laid down, shall be perpendicular from bottom to top instead of sloping, for that would let in the rain, whilst we want to keep them dry. Proceed with the second layer, so that the rims of the pots are 1 inch behind the rim of the first layer, and so on to as many layers as you can put on, and cover the top with ashes, litter, and a board. It is easy protecting such a ridge with litter when necessary. The pots will rarely be too dry all winter. The ridge should be broken down about the middle of March, and the pots set on their bottoms as, if they remained in the ridge on their sides, and the weather were fine after that time, the plants would grow one-sided. Some such arrangement will be useful to many amateurs, as they may rest assured that the frequent want of success is greatly owing to the plants standing in pots above the ground in all weathers, in winter. If the pots were even plunged, and a few leaves or some litter strewed over the surface, it would be a great improvement to standing them on the open ground. In the latter case the roots and crown are often exposed to such a low temperature as the plants would never experience if planted or plunged in the ground.

Picked out a few berries from Grapes that had signs of damping. On the whole they are keeping very well, but the floor of the house is not so dry as it ought to have been, owing to plants remaining rather long in it. Moved stove plants from vinery, pruned it, washed Vines, lime-washed walls, stages, &c., and will fill at once with bedding plants that are most likely to suffer from damp—as things that have been growing at all freely, though they may be kept from frost by covering, will not stand a confined damp atmosphere. Watered Vines in pit with manure water, heated to about 90°, and damped the stems a little. Manure water in evaporating-pans is the best substitute for a heap of fermenting dung in breaking Vines, &c.

ORNAMENTAL DEPARTMENT.

Placed peat and loam over furnaces to heat for top-dressing and repotting Ferns, stove plants, and fresh-casing baskets of Orchids. All stove plants are now kept rather cool and dry except those in and showing bloom. Not the best time for potting anything, but the little place being in course of repair and alteration, the plants have been squeezed in anywhere, and will need kind treatment to re-invigorate them. Used little water in conservatory, unless for Chrysanthemums, Cinerarias, &c. Hardwooded plants should have plenty of light and air. It is annoying to find the floor sailed from a watering-pot as in the dog days. Put a little fire on, to have all ready and in good order in case of a sudden frost, and have had all furnaces, flues, and chimneys looked at. After so much wet there is likely to be damp everywhere, and a brisk fire will dry all up and

make it fit for use. In long flues, with several turns, in a wall, we have had before now to pull out a smoke-plate some 20 or 30 feet from the furnace and put a bundle of shavings on fire there, to give a good draught and prevent our being smothered at the stovehole. By the way, there were lately some very sensible remarks on managing furnaces and regulating draught by the asphit doors; but the mischief is, you would require to have the eyes of Argus and feet that never weary, to keep such doors in order under the generality of stokers. Moved lots of Verbena cuttings and things of that sort where we could keep them drier. For Calceolarias and things of that kind a little damp does no harm. We are almost sorry that our Calceolaria cuttings in the pit are striking and pushing out roots. We should have liked it as well if they had not done so until after Christmas. They must have every bit of air that they can stand to keep them back, as they are so thick, and as yet scarcely one has done badly out of many thousands. We do not think we shall be able to thin them before March.

In answer to an "INQUIRER," we would say that if you can give no dry heat, the worst place in which you can preserve Verbenas, Petunias, Lobelias, and plants of that sort is an old hotbed frame. The damp rising from the dung, and from rain soaking into the dung, will be a constant annoyance. The frame set on dry ground would be worth a dozen of the old damp hotbed. A few of the earliest potted bulbs will now be fit for forcing in a mild heat. The rest must be kept from frost, whether for pots or the flower garden. Auriculas and Polyanthus of choice kinds should now be plunged in a cold pit or frame, and plenty of air given in fine days, and air back and front at all times, except when very frosty. They will need no covering unless the weather be very severe. Pinks not planted out, Carnations, Wallflowers, and early Stocks, Ten-week, Intermediate, or Brompton, had better be under protection for the winter. Tree Carnations will now be coming into bloom, and if well rooted will stand a little manure water. As already indicated, we have cleared a few beds in the flower garden for our fermenting-heap, chiefly in frosty mornings, as the lawn is very wet, and we do not care to thoroughly sweep the lawn until most of the leaves have fallen, which they will have done by the next frost. We will, if possible, take our Dahlias up this week. It is well to cut them rather high—say from 6 to 9 inches from the tubers—and lay them with the stems downwards in a dry place for a week. Then we place the roots in dry earth in a shed, and rarely lose one. The same earth has served for a number of years.—E. F.

COVENT GARDEN MARKET.—Nov. 14.

The market continues well stocked with all kinds of fruit and vegetables in season. Hot-house Grapes are both good and plentiful, especially Black Hamburgs. The supply of Pines is very abundant, but for those of the best quality prices have not retrograded. The best dessert Apples consist of Ribston Pippin, Cox's Orange Pippin, King of the Pippins, and Golden Reinette. In Pears, Glou. Moineau, Chaudmontel, Winter Nellis, and Passe Colmar are the leading kinds. The best Cobs maintain the prices previously quoted, 65s. to 70s. per 100 lbs. Cut dowers are the same as last week.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

PRUNING PILLAR ROSES (T. G.).—Roses grown as pillar or climbing roses require to be pruned on a different principle altogether from standards. For a pillar we shall presume that the plant has five shoots. Select the strongest and cut it back half its length, the next strongest two-thirds of its length, and the remainder are to be pruned to four eyes each. The leader will push some five eyes, the uppermost of which is to be trained to the pillar, the remaining four shoots being also tied if there is any danger of their becoming broken in a gale. The shoots made by the leader are to be pruned precisely in the same manner as in the previous season, and all below pruned to four eyes, and so on year after year until the pillar is covered, when the shoots are pruned to four eyes from top to bottom. If they are to be trained against a trellis or wall select the two strongest shoots, and bring these down towards the bottom, and having cut them back half their length, nail or tie at about 1 foot from the bottom, letting the shoot rise from the stem 1 foot in a yard distance. Take the two next strongest and cut them back two-thirds of their length. These are to be trained about 9 inches above the other shoots. The remainder being equally distributed towards the centre, and three shoots are ample to cover or fill the centre, cut two to six eyes, and the centre shoot to four. The season following the shoots on the old wood are to be cut to two eyes, and the leaders of all the branches to half their length, except those in the centre, which are to be pruned to two-thirds the length of each. Proceed in this way until the allotted space is covered, when closer pruning is requisite for the whole. You will attend to the cutting out of an old branch in after years, and supplying a young one in its place, taking such shoots from the base of the plant. Out of those you named you will prune Breous and Gloire de Dijon less than the Hybrid Perpetuals.

TRANSPLANTING ROSE TREES (Idem).—You may move the budded roses now, the sooner the better; but do not cut off the part above the bud until the beginning of March.

PAMPAS GRASS NOT FLOWERING (Idem).—The Pampas Grass is evidently suffering from want of moisture at the root. You will do well to add some strong clayey loam to the soil about the plant, and water copiously with weak liquid manure twice weekly in droughty weather. We think your plant would then not only flower but be very fine, amply rewarding you in due time for the labour bestowed. Rivers's Rose Catalogue will meet your wishes.

PROTECTING YUCCA FILAMENTOSA (A Cottager in the West).—If you leave the plant out the best thing would be a hood of mat or calico, or canvass made waterproof, to set over the plant every night, and to keep it on if the weather should be frosty during the day. The plant is hardy, but the frost will injure the flowers if severe. If you are very anxious the plant could be raised carefully with a ball and placed in a tub or pot, and set indoors until the blooming was over. We presume the dry summer has caused it to bloom so late. The same crown will not flower again, but fresh crowns will bloom when strong enough.

HEATING PIT FOR BREDDING PLANTS (A. A.).—You would see an answer to a correspondent last week how that could be done by taking a flue underneath with a chamber over, and openings to let the heat up. A small flue at the side would answer the same purpose. All could be saved without artificial heat, if covering up from frost is attended to, in frames set on raised ground, banked up all round, the outside coated with tar and sand, and for a yard or 4 feet all round to send off the water. For single frames, say of one or two lights each, earthenware gallon bottles filled with hot water would be serviceable. For a number of them the cheapest thing would be a small furnace, a yard or 2 yards of brick flue, and then common drain tiles about 7 or 8 inches in diameter, and to be used only in damp or frosty weather.

PLANTS BUT NO GREENHOUSE (Economy).—Your best plan would be to try a spare room for your plants. Such a contrivance as you speak of, covered with oiled paper, would do from the middle of April to the middle of October, but you must keep the wind out even then. Calico glazed or painted with dried oil and a little bees-wax melted in it would be better, and if well tacked to the wood would last some time. You are just the sort of person to have a small greenhouse, fixed roof, wooden ventilators at the top and front, and glazed with glass at 2d. per foot, warmed by a brick Arnott stove to keep out the frost. Rafter sash-bars 3 inches deep would do for 16 ozs. glass if the house were not more than 6 or 7 feet wide, and that in a few years would be cheaper than your temporary paper frames, though with these many good plants have been grown. Command us if we can do anything for you.

FUNGUS ON TANNERS' BARK (A Novice).—It is not injurious to plants; but is unsightly, and may be destroyed by frequently stirring the surface.

GABBENS WORTH VISITING (R. H.).—All those omitted from your list had been published by us previously, as you will see if you refer to some of our back Numbers.

NASTURTIUM [TROPEOLUM] (A Lady Subscriber).—It is impossible to judge of the value of a Nasturtium from a single crushed bloom. Everything depends on habit and on the colour of the fresh flower.

AQUINO DONAX CULTURE (R. Powles).—We should prefer the south-east border. It requires nothing beyond common soil to grow in, and does best planted near water, so that its roots may feel the benefit of it.

SURFACE OF PIPING REQUIRED (T. H. J.).—Your first letter was destroyed long ago. If we kept MSS. we should require no end of warehouse-room, so we cannot say anything about the Arnott's boiler. You had better repeat the question. Your two four-inch pipes for ainery 30 feet by 9 will not be sufficient for early Grapes nor yet early Cucumbers. You would need, at least, one pipe more all round the ends and front. If you took the two pipes all round the back as well as front and ends that would be sufficient. You say nothing how you propose arranging.

LONG SHOOT OF BANKSIA ROSA (H. G. M.).—Cut it back half its length and bend the upper part of the remaining half down, to induce the eyes to break from the bottom and all along the branch. If failed-in now it will only break a few eyes at the top. After the shoots are a few inches in length it should be nailed to the wall.

VANISHING CALICO (Idem).—To render this a substitute for glass, use linseed oil one quart, acetate of lead one ounce, white resin three ounces. Grind the lead with a little of the oil on a stone slab; add the remainder of the oil and the resin, and incorporate thoroughly in a large iron pot over a slow fire. Apply whilst hot to the calico stretched loosely, by means of tacks upon the frame. When cold it is fit for use, and may be tacked on the frame tightly, putting a piece of tape between the tacks' heads and the calico. The composition should be applied with a brush.

WINTERING CALADIUMS (George Linn).—When the roots are kept dust dry they are apt to become farinaceous, and though hard and apparently plump and sound when potted in the spring, they not unfrequently rot on water being applied or on placing them in moist soil. We should place them on the floor under the stage, and if it is rather moist the pots will absorb moisture enough to keep the roots at rest still fresh. Do not water now, but place them on a moist floor under the stage of the stove, being careful that water does not drip from the pots above and make the soil in the pots sodden.

AZALEAS INFESTED WITH THRIPS (Idem).—We told you before how to kill thrrips on Ferns, and we can only repeat:—Smoke strongly two nights in succession, and syringe the plants the morning following each operation. Gishurst compound at the rate of 4 ozs. to the gallon of soft water, is an effectual remedy for thrrips, but it should be washed off with the syringe twelve hours after it is applied.

SEEDLING RHODODENDRONS DECAYING (S. B. O.).—Your seedling Rhododendrons are, we fear, standing too close together, and in a soil the reverse of sweet, or in that which is rendered sour by stagnant water. Perhaps you are using the old soil in which seedlings have been grown before. Any of these causes will produce the disease known to gardeners as "damp." Irrespective of these causes there are changes continually going on in the atmosphere which produce those diseases of fungoid origin which puzzle even the most experienced. The disease is brought on by a deficiency of one or more of the elements, aerial or terrestrial, necessary to the proper constructing of the plant's several parts, but what that deficiency is remains, and we fear will for some time be one of the problems that science fails to solve. We know of no remedy but exposing the plants to the full influence of air by taking off the lights, and stirring the surface soil, and thus making all sweet about them. Self-sown plants, we may add, never go off in the way yours are doing, and this we think is owing to their receiving thorough exposure to the air, which secures the opposite of draws, imperfect-structured plants, such as too often result from artificial rearing.

CONSERVATORY ROSES NOT BLOOMING (J. J. J.).—You do not say what kind of roses yours are. There is, however, but one mode of treatment, so far as potting is concerned, necessary for them. They should be potted in September, and plunged in ashes in a cold frame. Air is to be given by taking off the lights in mild weather, letting the plants have the benefit of gentle rains; but putting on the lights during drenching rains, and to shield them from frost. In November the plants should be pruned. Teas and Chinas require but little pruning, merely taking out the wood that has produced flowers, and shortening the shoots retained. Perpetuals require pruning to two or at the most to four eyes; Bourbon, Moss, and Provence must be pruned moderately. The beginning of February is early enough to introduce them into the conservatory, where they should be placed in the coolest part for a fortnight, sprinkled morning and evening with tepid water, and copiously supplied with water at the root. They may then be placed in the warmest part, if not above 50°, where, with abundant ventilation and light, they will flower in due season. Return them to the garden in summer, plunging them in ashes until September, when you will pot them and place in the cold frame as before. As your plants are now in the conservatory, prune them at once, and keep them as cool as possible, and rather dry at the root, until Christmas. After that water more freely, and bedew the plants overhead morning and evening with the syringe. Give all the air and light practicable, and be careful not to let them want for water at the root.

DOUBLE PRUNIUS CULTURE (Idem).—Take out greater part of the old wood, cutting this year's blooming-shoots clean out, leaving nothing but young wood to grow and bloom another season. They require to be kept moderately dry during the winter, and in a cool and dry atmosphere with a temperature of from 35° to 40°.

USE OF A SPARE ROOM TANK-HEATED (M. B. T.).—You might force Asparagus, Rhubarb, and Sea-kale in your spare room; or, if you could obtain some horse-droppings, sufficient to make a bed 6 inches thick, you could have a crop of Mushrooms. In January you could sow Cucumbers, and have some nice fruit in April; and in March you could sow some Melon seed, grow on in pots, and plant out in May, and these would give you some fine Melons in August. Or you might have some Vines in pots plunged in the soil, and train the canes to the roof, about 1 foot from the glass; keep them there until the fruit change colour, when they will be none the worse by being removed to a drier atmosphere to ripen. Last, but not least, it is just the sort of place wherein to place any sickly plant, and, if you could lower the temperature, to bring forward such things as bulbs, Roses, Dielytras, Deutzias, Rhododendrons, and Azaleas. These are a few of the uses to which the space might advantageously be employed, and to them we think you might add many more.

PRICE CATALOGUES OF FAVIT TAERS (H. Hawkins).—We have no such publication. You had better write for them to some of the chief nurserymen.

SUPPLEMENT TO COTTAGE GARDENERS' DICTIONARY (Isora).—No supplement has hitherto been published, but one is now ready and will soon go to press.

CONVERTING A GREENHOUSE INTO A VINERY (Ely).—Our friends who wish for an answer to questions in next week's impression should let us have their questions in the beginning of the week. You very modestly propose two questions, but these involve ever so many, and a full answer to them would need a whole Number of this Journal. Most of them have recently been discussed in detail, so we must be brief. We should have fully comprehended your span-roofed greenhouse, facing east and west, 30 feet by 17, if you had given us the height at sides and the height of the ridge-board. The height at the sides, wall and glass, would have given us the key-note for the forming of your borders for Vines. Glass in squares, twenty-one inches, and in such large squares as 20 by 16 inches, should have braced at their lower ends at any rate, besides the duty to keep them from slipping. A brad to the middle of the square in such a case, with a slice of india-rubber beneath it, would make all more safe, especially if the rebates are very shallow. If at all deep, they will not be needed. There are plenty of offices which insure glass houses against injury from hail-storms, &c.; but we cannot take upon us to recommend any office in preference to another. A gravelly and sandy soil, if the two first are in excess, will not grow Vines successfully; but if deep and open it may be enriched with manure and loam, and some chalk or lime rubbish and a few bones. If the gravel and sand are unhealthy to vegetation, some of the cleanest gravel and sand should be used with lime, in the proportion of six parts of the former to one of the latter, to make a concrete bottom of 3 inches, and on that place good fresh loam for the Vines. If other things grow well in your sandy gravelly soil, the Vines will also do well with the addition of a little loam and manure, the latter chiefly as top-dressing. For making borders, see notes on Kew Hall, and notice of Trentham at page 374; but if you merely wish for late Grapes, and the soil is at all favourable and no chance of stagnant water, you may add a little fresh soil merely on the top of the old, mixed or not mixed with it, as you will shortly see was done by Mr. Lane at Herkhamstead. In general cases the preparatory mode will be found the best in the end. We prefer the Vines to be planted inside, and would have the roots to run there as well as outside. The outside border might be from 8 to 10 feet wide. You might have eight Vines on each side if you chiefly wish for Vines; and if you wished these to be forced early, or to have little forcing at all, but to be ripe and cleared off in the autumn—say by the middle of October—then nothing would be better than Buckland Sweetwater, Royal Muscadine, and different varieties of Black Hamburgh. You might also add a plant of Hamburgh Muscat and Moscat of Alexandria. If you wished the Grapes to come in late and bang during part of the winter on to the spring, then to the above add the Trebiana, Charles-worth Tokay, and Lady Downes' Black. If you propose growing fruit trees in such a house, there will be no difficulty; but the five Vines on each side would be enough, and you make your house a fruit-house and not a greenhouse. A good arrangement for such a house would be a bed in the middle 7 feet wide, the path round 24 feet, side borders 24 feet. Any small saddle-back or conical boiler would do for such a house, increasing the size according to what you want from it. It would be placed best at the end of the house, next the range of pits to be heated. We have frequently described how different places may be easily heated from the same boiler. The quantity of piping would depend on the time Grapes were wanted, and two four-inch pipes all round would be ample for general purposes, and these would be placed side by side on the side and end borders, avoiding the doorways. For very early forcing a third pipe would be necessary, or a couple of pipes might go under the central bed, with clickers or stones round, and then either or other matter to set the pots in. The top spit from a pasture—or rather 3 inches of it piled in a heap for a few months, with layers of branches in it to let the air through it—would be in capital order to be chopped roughly down in six months. Any fresh soil beneath turf, or from a roadside, may be used at once if you deem such fresh soil necessary, and certainly it is safest. The great thing is to avoid stagnant water and the roots getting too deep. The time of planting is immaterial. It planted now and well mulched the roots will begin to make fresh fibres at once. If planted in March and a little heated soil is used and warmed water also, they will soon start away. If you can grow the Vines inside until June, you can plant out then and shade a little to prevent a check. In every case the roots should be carefully spread out. In that the best plan of all, if it could be done, for quick work, would be to turn out the roots in spring carefully into shallow baskets some 2½ to 3 feet in diameter. Grow them inside a warm house and then plant out in fine aired soil in June, planting basket and all together. Planting inside, however, you may do at any time when the ground is ready. With Vines thinned on the roof, the plants in pots will do very well.

TRANSPLANTING PEACHES, APRICOTS, &c. (Idem).—There need be no hesitation in moving these trees, eight or ten years old, from one garden wall to another, and the sooner it is done before the ground is cooled the better. Prepare the ground where the trees are to be planted, unfasten the trees and fasten the branches in bundles so as not to be broken. Then dig down a deep trench near to where you may expect the extremities of the roots to be, and pick down and throw out the soil in the face of the trench, saving every root that comes in your way, and thus go on until you get up to the tree, wrapping the roots, if the weather is at all dry or sunny, in damp mats. Carry the tree with all its roots thus secured to the new place, and pack the roots nicely in the fresh soil, and the bulk of them to be 6 or 8 inches from the surface. Light sandy soil will be the best to pack them in, and then place the other soil over and fasten down moderately, and place a good layer of litter over the soil to keep the frost out. Most likely if thus managed the trees will be improved by the moving. But in order to give them a first-rate chance, whilst these means are used to encourage root-action, keep the shoots from the wall as long as possible that they may be kept from swelling their buds too soon.

ASPARAGUS-BED-MAKING (A Reader, Bingley).—If the soil is light, rich, and deep, 6 inches of well-rotted manure, worked-in in treaching the ground 3 feet deep, is a good preparation, the bed being made 5 feet wide, with two feet alleys between. In very cold heavy soils it is advisable to take out the soil to the depth of 3 feet, and fill in 6 inches thick of charred turf at the bottom, then 6 inches of manure, 3 inches of river sand next, then more turf, or moderately light, good-bodied soil, manure, and sand, until the whole is raised level with the surface. Having an opening at one end, turn the whole over, mixing it well together; and when that is done, throw out the alleys 1 foot deep and 2 feet wide over the beds on each side, which should be 5 feet wide. The ground being well drained previously, and proper care taken of the beds afterwards, good crops will result.

PAPER DRAPERY (Paper Drapery).—We cannot find such an advertisement in our columns.

PRONUNCIATION OF CYCLAMEN (A Subscriber).—It is pronounced as if spelt Sick-lamen.

ASH-BARK FOR EPILEPSY (Charlotte).—The bark of the female Ash-tree (*Fraxinus excelsior*)—that is, a tree bearing fertile keys, differs in no known quality from the bark of the male, or non-seed-bearing tree. Some Ash trees bear both fertile and unfertile flowers.

OUVIRANDRA FENESTRALIS CULTURE (Anxious Inquirer).—Your treatment is right, except that you are ignorant of the grand secret in growing it—"Keeping the leaves free from dirt, and all about it sweet." A successful cultivator furnishes us with the following particulars of its cultivation:—"It requires a temperature of from 70° to 75°. Broad glass pans are most suitable for it, as they allow of the structure of the leaves being perfectly visible from the light transmitted through the sides. The compost consists of fibry peat with a little rotten turf. This is put at the bottom of the pan to the depth of 3 inches, and is covered with half-an-inch of river sand. The sand is to prevent the water becoming discoloured or dirty when the plant is syringed. It is watered with the syringe every morning, taking care to use water of the same temperature as that in which the plant is growing. This syringing frees the leaves of any sediment that might adhere to them, and prevents green slimy moss forming in the water. The sides of the glass require rubbing occasionally to keep them clean. Early in spring the soil is renewed, as the leaves begin growing smaller and weaker when the soil stops in too long. The soil is only changed once a year." You did quite right to report the plant when you found it was not doing well, as that, it seems, is one of the main points to be attended to.

PLANTS FOR A SHADED CONSERVATORY BORDER (F. N.).—Ferns are more adapted for such a border than Heaths, which require, and must have, sun, light, and air. The various multifid and elegant varieties of the British species of Ferns would be charming in such a place, grown in pots or planted out. We know of no flowering plants that would do in such a place as that you name.

CREPERS FOR CONSERVATORY PORCH (Idem).—Those you name would do very well. *Wistaria sinensis* is a handsome fast-growing plant, and so is *Clematis lanuginosa*, the former flowering in spring and the other during the summer. Of evergreens there are *Caprifolium japonicum*, sempervirens, and *Younghii*; *Lonicera brachypoda* and *flexuosa*; and *Jasminum revolutum* and *Wallianum*. *Magnolia grandiflora*, and *Crataegus crenulata*, *Pyra-cantha*, and its variety *fructu-albo*, are handsome evergreens.

EARLY-FLOWERING ANNUALS (Agnes).—Sweet Alyssum; Campanula Lorei; Clarkia pulchella var. Tom Thumb; C. pulchella and alba; Gilia bicolor and tricolor; Echeardium grandiflorum; Gypsophila muralis; Collinsia atrovirens, bicolor, bartschfolia, and bart-nefolia alba; Eschscholtzia californica, and crocea alba; Silene pendula and alba; Limnanthes grandiflora and alba; Lupinus ninus and nanus albus; Nemophila insignis maculata; Nolina atriplicifolia, alba, and paradoxa; Venus's Looking-glass; Leptosiphon aureus and densiflorus; Candytuft; and Erysimum Peroffskianum. These, with many more, bloom early. March is the best time to move them, though we have found very little difference between those moved in October or the beginning of November, and those transplanted in March. The grand secret is to lift them with balls, and to disturb the roots as little as possible. All transplant well with balls of earth attached to them.

HIPPEASTRUM FLORESCENS (A Subscriber since 1856).—It is an evergreen from the West Indies. Your treatment is quite right so far; but you should have gradually withheld water from the beginning of October, but not so much as to suddenly cause the leaves to turn yellow. Place on a shelf in the stove, allow them all the sun and light practicable, and give very little water during the winter—that is, from November until the beginning of March. It is not necessary to put them to rest by drying-off the bulbs, as that de-toys the roots in the pots, which we are certain weakens the bulbs. *Cleopatra* and many others do not die down unless compelled by withholding water. We do not recommend that plan, but recommend the roots to be kept dry for a period of three months at the duldest time of the year, and to give them more sun, light, and air, at that period than any other, and a corresponding dryness. You are quite right in giving them plentiful nourishment after flowering; in fact they cannot be encouraged too much for three months after flowering, or until the foliage attains its full size. After that time water should be gradually withheld, so that they will need very little indeed during the winter. We will attend to your other inquiries.

WINTERING PELARGONIUMS AND YOUNG HELIOTROPES IN A ROOM (An Old Subscriber).—The plants you have managed to strike out of doors, and establish in four-inch pots, will no doubt succeed well under the same care as that which has brought them thus far. A room is a very good place to keep such things, provided there be plenty of light, and the plants be placed near the window. Pelargoniums are quite as hardy as bedding Geraniums of the scarlet or similar breeds, and will endure quite as rough usage; but there is a wide difference between wintering plants for the flower garden and preparing tidy plants for keeping in pots to flower. In the latter case nice-shaped plants are required; in the other, shape and symmetry are of little moment. However, by giving the best places to those plants which are required for retaining in pots, they will be better shaped; but you can hardly expect to compete with those having better means. Your Heliotropes will keep very well if you do not give them too much water. Perhaps, however, the foliage may become a little disfigured during the short days, but they will grow well enough afterwards, and afford cuttings to propagate from in April, when they root freely. If the room they are growing in be not too dry, we do not think bell-glasses will be wanted, excepting for plants not sufficiently rooted. You are perfectly right, however, in trying such experiments, and we hope to hear from you again. Perhaps the next time you will favour us with the result of your experiments in some department that will be adaptable to other of our readers.

NAMES OF FRUIT (T. A., Dorchester).—It has now "come to your turn." 3, Passe Colmar; 4, Swan's Egg; 5, Uvedale's St. Germain; 6, Nonneau Poiteau; 7, Fleamish Beauty; 8, Veau of Winkfield; 10, Chaumontel; 11, Comte de Lamy; 13, Shepherd's Seedling; 14, Bedfordshire Foundling; 15, White Costing; 16, Trumpington; 17, Court of Wick; 18, King of Pippins; 19, Dunelov's Seedling. Others not identified. (An Old Subscriber, Elmton).—Pears.—2, Nonneau Poiteau; 3, White Doyenné; 4, Neill; 6, Madame Elize; 7, Comte de Lamy; 8, Van Mons Leon le Clerc.

Apples.—1, Lemon Pippin; 3, Braddick's Nonpareil; 5, Striped Queening. Others unknown. (*R. B.*).—*Apples*.—12, Hawthornden. *Pears*.—2, Vicar of Winkfield; 3, Forelle; 4, Passe Colmar. The others cannot be identified. (*A Pear-Grower*).—Too decayed to be identified. (*T. G.*).—*Pears*.—2, Beurré Langueval; 3, Crasanne; 6, Crasane; 7, Winter Nelia. *Apples*.—1, Altristron; 2, Fearn's Pippin. Others not recognised. (*R. Webb, Colcot*). The high-coloured Pear is Veurré Clairgean, and the greenish-yellow one is Conseiller de la Cour. Very fine indeed. The baking Pear is Winter Franc Real. The Pears Croft Castle and Wormsley Grange were delicious. The two nuts Webb's Cob Filbert and Thin-shelled Deviana are, perhaps, the largest and best we have seen.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (*R. S.*).—1, *Thuja tatarica*; 2, *Thuja Menziesii*; 3, *Biota orientalis gracilis*; 4, *Thuja plicata*. (*Zeta, Red Hill*).—1, *Funkia alba-marginata*; 2, *Thuja pendula*; 3, *Cupressus sempervirens*. (*A Subscriber*). Doubtless a *Callistachys*; but we cannot determine the species without seeing another flowering specimen. Send us a flowering sprig in a little damp moss. (*J. C.*).—Your Ferns are—1, *Lastrea Filix-mas*; 2, *L. dilatata*. (*Miss Walsh*).—Your bulb is *Nerice undulata*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

ABOUT MANY THINGS.

"AN EXHIBITOR IN A SMALL WAY," pours out his griefs in a recent Number of your Journal, and seems to imply a want of fairness in the management of poultry shows. I am also an exhibitor in a small way, and I have had my share of disappointment both in prizes and in sales; but I cannot agree with your correspondent altogether. There are many mistakes—there is occasional unfairness: I do not see how these things are to be avoided. There is, on the other hand, a natural disposition in exhibitors to grumble at want of success, and to have an impression that their own pens must be the best.

Supposing unfairness or carelessness on the part of judges and others at shows, there is a remedy in the hand of every exhibitor, which I mean to use vigorously as soon as I come across too glaring a mistake or the shadow of dishonesty. The awards cannot be altered, but the shortcomings of judges and of officials can be posted in the newspapers, and nothing would more shake the system of prizes and sales at shows than a suspicion of dishonesty or carelessness. The amount of money and time expended to produce birds worthy of exhibition deserves the strictest honesty and the greatest care. I recommend exhibitors to agitate publicly every want of honesty or care, making due allowance for the difficulties that both judges and officials have to contend with, not overestimating their own stock or suffering themselves to be blinded by prejudice or disappointment.

At the recent Crystal Palace Show I failed in all that I tried for, both in prizes and in sales; but from my own observation of the Show I was perfectly satisfied. I saw mistakes there—to wit, a prize Game fowl whose legs were faulty; a prize Sebright with more than what Mr. Bailey calls the "suspicion of a sickle feather." By the way, all the Sebright hens were to my mind faulty in the comb. We do not raise such birds as old Sir John's. I saw birds, very many of them as good—or so nearly so that it was hard to tell the difference—as the prize birds. I saw birds marked in the catalogue at ages which I am sure were incorrect. But I really could not find any reason for a complaint of either carelessness or dishonesty, nor do I think that small exhibitors had less chance than others. For my own birds, I must say that they received the greatest care, came back to me quickly in as good condition as I sent them, whilst I am bound to acknowledge the civility and attention of the attendants and the courteous painstaking of the Secretary.

I mean to try my luck at Birmingham with some very choice pens, and I shall be perfectly content if I am beaten by better. I cannot suppose for a moment that there will be any shelving of small exhibitors; should it be so, you will hear from me again, and I should state the unfairness in several other papers.

I do not like the rumour that the Committee of the Birmingham Show mean to confine the poultry exclusively to the poultry bay regardless of the amount of entries. Either let them close their entries or procure sufficient space. They will I am sure act fairly in this, as well as in seeing to the size of the pens for the larger varieties—a great want in former shows.

I would exhibit also at Manchester, which Show is second to none in fairness, care, and punctuality, but that I agree with another of your correspondents in objecting to the employment of people away from their homes on Christmas-day, and I do not choose to have my birds exposed to a blank day in the middle of the Exhibition, on which day a certain amount of negligence might naturally be expected. I hope that this second hint to the Manchester Committee may be taken, or that exhibitors who have not entered will withhold their entries. Exhibitors have a great power in their own hands if they use it with temper, fairness, and discretion. Small exhibitors cannot expect the success of great exhibitors, any more than small traders can hope to make the profits of large ones. The field is open to all, and shows will depend very much upon small men, who, of course, in this, as in everything form the majority. A small man who can hit hard and fight fairly, is a troublesome fellow amongst dishonest men. Honesty is the best policy, if it is not anything more; and if poultry shows are to last and be profitable, they can only be upheld by straightforwardness on both sides.

The suggestion of your correspondent that you should "set apart a column of your paper, in which your subscribers could for a small fee insert their wants, whether of buying, selling, or exchanging, without the formality of an advertisement," is a very good one; I hope you will find that you can carry it out. To this I would add, that you might publish after every great Show a list of the pens sold, their prices, names of exhibitors, prizes, &c., as a supplement to your usual account and prize list.—EOMER.

SHEFFIELD AND HALLAMSHIRE FANCY PIGEON SOCIETY.

THE fourth annual exhibition for this year's birds was held in the large club-room of the New Inn, Shales Moor, Sheffield, on the 2nd inst.

There were more than two hundred birds shown, including old ones; but the prizes were given only for young birds of this year. In *Carriers*, Mr. Colley took first, second, and third prizes with three splendid birds, Mr. E. Brown coming in fourth. In *Pouters*, Mr. W. Taylor stood first with a Mealy cock, also fourth with another of same colour; Mr. Ashforth second with a good Blue; the third went to Mr. Smith. *Fantails*, Mr. Smith took first and second; Mr. Taylor third and fourth. *Owls*, Mr. Wilkinson first and fourth; Mr. Benninson, second and third. Variety Class, Mr. H. Brown first; Mr. Ashforth second and third.

There were some very good old birds shown in *Carriers*. Mr. Colley was greatly in advance of the other members. A pair of good Duns, which took first at Collingham last week, were shown by Mr. E. Brown.

Mr. H. Brown showed some excellent *Pouters*, including Red, White, and Yellow; one of the last colour he sold for a good sum. Mr. W. Taylor, also, had some very good Blues and Meales, and a large Mealy cock that has taken several prizes. Mr. Simpson, of Newark, brought a few good *Pouters*, also a beautiful pair of Yellow Short-faced Mottles. There were *Owls*, *Turbits*, and other sorts shown by different members of the Society.—E. B.

BRAHMA POOTRAS NOT WELL ENCOURAGED.

ALLOW me most fully to endorse the facts and opinions contained in the letter of your able correspondent "Y. B. A. Z." We all know that the most "rising" fowl of the present day is the Brahma Pootra, and yet it is equally certain that this fowl is more hardly used and more systematically discountenanced by the managers of shows than any other kind. Compare, for example, the treatment of the Brahma with that of the Polish fowl, which latter is so feebly represented in point of numbers at our great shows. There were only four pens of one variety and a single pen of another variety of Polish fowls at the Crystal Palace, and yet these five pens competed for precisely the same sum in prize-money as was offered to all the pens of Brahmas, twenty-four in number.

Again: in spite of what your correspondent points out,

that the Brahma brings in a better return in entrance-fees as compared with the prize-money than any other class, with but one exception, yet at Birmingham £13 only are offered to Brahmas, and just three times as much (£39) to Poldands. Such facts point unmistakeably to a revision of prize schedules.

When this takes place let it be remembered that there are two varieties of the Brahma fowl, both, according to the high authority of Mr. Baily, equally genuine, and further that one of these, the Light Brahma, excelling, in the opinion of many, its Dark rival in usefulness and beauty, boasts a large and growing number of supporters who can ill brook its practical but unjust exclusion from prize lists, owing to the paucity of prizes given in the Brahma class.

The division of the Brahmas into two separate classes is imperatively demanded both by the growing numbers of the specimens exhibited, and still more by the practical exclusion of the Light birds under the existing system.—**BRADDA POUTRA.**

PREPAYING FOR POULTRY.

SEEING a letter in your paper relative to prepaying for poultry, I beg to acquaint you that in two cases that I have done so I never received any fowls, and in another case they did not answer the description given, yet the seller refused to take them back, and he having the money I could do nothing. Under these circumstances I should recommend that no prepayment for fowls be made, as the purchaser is as likely to be honest as the seller.—**CONSTANT READER.**

[If a purchaser buys fowls which he has never seen from a person he does not know, he voluntarily incurs a far greater amount of risk than common prudence justifies. If we were wishing to make a purchase under such circumstances, we should merely give a reference to some respectable well-known party, and stipulate with the seller that we should be at liberty to return the poultry, paying all charges if they did not suit. In a transaction of this kind both purchaser and vendor should cheerfully allow to one another the exercise of common precaution.—**EDS.**]

EXHIBITING POULTRY PROFITABLY.

ALLOW me to address a few lines in reply to "AN EXHIBITOR IN A SMALL WAY." The result of my experience for two years is that an exhibitor of his class may add profit to the pleasures of prize-poultry-breeding if he go the right way to work; but in this, as in all else, there is a right and a wrong way, and among so many it is natural that many should never find out the right, and give it up in disgust. There are people who have mistaken their calling, and who never should have attempted to keep poultry for any but domestic purposes. But let the right way be adopted by the right man, and I will guarantee that not only profit but very considerable profit will ensue, and such as shall be a tangible addition to a moderate income.

First we must assume that he starts with really good stock, which, if he has an eye and has friends to advise, he may pick up cheap enough by looking about; and if he intends to do it well, with a view to pleasure and gain, I advise his confining himself to getting a name for one sort only. The trouble and vexation of trying various sorts at once is to my mind a nuisance, and the confinement it entails upon the birds prevents their keeping good health and plumage, and does away with the pleasure of seeing them roam at their ease.

As a beginner, I do not consider one should expect to sell many pens at shows, however they are marked, and that must not be too low.

On the contrary, what a young hand should aim at is to send good birds, and endeavour gradually to get his name up for a certain breed. As soon as he is mentioned, or takes a prize or two, he will have a few isolated applications for stock, which let him reply to by always supplying a good bird. But this must not suffice; he must now begin gradually to invite a wider sphere of demand by going through what he calls "the formality of an advertisement" in your Journal. If he is too careless or proud to adopt the great medium of the age, it will only be by a miracle that he can work his way to fame.

But, then, let him beware of the "Long firm." He must make a rule not to send a single bird away without the money, unless it be to a known correspondent, or he will assuredly be victimised. Let him make a point of sending out good birds at good prices; and if he has second-rate ones to sell he should detail their chief faults to his customer, who can take them with faults at a lower price if he chooses.

If he adopt this plan he will be sure to have quite enough demand for his stock if he repeat his advertisement from time to time; and my accounts show me that a man may, when once warm in the subject, easily add a hundred or two a-year to his means fairly and honourably.—**ONE WHO DOES NOT MIND THE FORMALITY OF AN ADVERTISEMENT.**

THE BIRMINGHAM SHOW.

THE entries for cattle, poultry, and roots having closed, we are now in a position to speak with certainty upon the prospects of this year's Show. Of late years each succeeding Show has, either in special departments, or, as a whole, developed its growth so rapidly that it seems almost impossible that its dimensions could be included within the limits of the space comprised within the walls of Bingley Hall. The difficulty in the way of space has been met by the erection of a new gallery over a portion of the bay, adjoining that in which the poultry are exhibited. This gallery will be devoted to implements, which department last year completely overran the space set apart for it. Implements will also be exhibited on the floor space. It will be remembered that at the last annual meeting the propriety of exercising a stricter supervision of the entries in this department was discussed. The Council, having discussed the subject, adopted the following resolution:—"That it be a recommendation to the Council in future to restrict the articles admitted for exhibition, in addition to stock and poultry, to agricultural and horticultural implements, tools, and machinery, roots, grain, and articles to be used in connection with agricultural and horticultural pursuits." To a great extent, no doubt, this resolution will meet the evil, though at first the remedy will not be complete, inasmuch as exhibitors are not required to send in a complete list of their implements, and there will be sure to be some articles creep in that do not come strictly within the prescribed regulations. The entries of cattle are fifty per cent. above the average of former years. The sheep, though somewhat fewer than last year, which, by the way, was exceptionally strong in this department, are also fifty per cent. above the average of the entries of former years. In pigs there is an increase of twenty-five per cent. The new poultry department has always been a strong feature in the Birmingham Show—indeed, one of the main features that have tended to make the Show famous. This year there is an increase of a hundred and fifty in the number of entries as compared with last year. The show of roots, though not one of the most attractive, is at all events one of the most useful departments of the Exhibition, and shows signs of healthy vigour. This year corn has been added to the roots, and the propriety of the addition is shown by the fact that there are fifty-seven entries. The new gallery to which we have referred above is intended for implements only; and to make room for the large increase in the other departments the Council have been compelled to deviate from the former planning of the Exhibition space appropriated to cattle, sheep, and pigs. The main central avenue will be slightly contracted, and down the two side avenues for cattle will be placed double rows of pens for sheep, while the space formerly occupied by the sheep will be taken up by an extra row of cattle. There will be one row of pigs in the old position, and the remainder of the pigs will be shown in the small corner bay beyond the second-class refreshment-room. An improvement has also been effected in the poultry department, by increasing the size of the pens for the Cochins and Dorkings. The following is a list of the entries, showing also the numbers last year:—

	1863.	1862.		1863.	1862.
Cattle.....	164	131	Corn.....	57	—
Sheep.....	92	110	Poultry.....	1,500	1,364
Pigs.....	93	70	Pigeons.....	275	232
Roots.....	124	116			

This year the public will be admitted on Saturday, the

28th inst., the day on which the Judges make their awards. The reason for this innovation is that some exhibitors have expressed dissatisfaction that the judging should be conducted in private, and the Council have therefore determined to give this privilege on payment of an admission fee of ten shillings. It was deemed necessary to fix the admission fee thus high, in order that the Judges might not be impeded by a throng in the performance of their arduous duties, and also not to interfere with Monday, the day of the private view. The poultry will not, however, be exhibited until the Monday.—(*Midland Counties Herald*.)

ISABEL PIGEONS.

IN reply to Mr. Brent's note in last week's JOURNAL OF HORTICULTURE, I, having bred several pairs of Isabels during the last and present year, willingly tell you all I know about them.

I purchased my first pair of Lady Winchester, and exhibited them at the Crystal Palace last December, where they took second prize. They were in moult this year, or I should have shown them again. Lady Winchester informed me she never let them rear their own young, implying that they were bad breeders; but I thought I would try them, having but little room for nurses, and the result is as above stated, I never having shifted their eggs; still I must admit it is desirable to keep them in a pen when breeding, that the young may be easily looked to, as they will sometimes neglect them, and let them die from cold with their crops full. Some will breed much better than others.

A gentleman in Glasgow whose name I forget, and with whom I exchanged a bird, told me that they are in some parts called Austrian Powters, and they certainly have some of the properties of the Powder, such as the power of filling out their crops with wind—female as well as male. They are very fond of "showing," and the young cocks very precocious, calling to nest at a very early age. They are rather smaller than Trumpeters, which they resemble about the feet and legs, being heavily feathered and vulture-hooked. Some are nearly as upright as Powters. They should be a rich cream colour with white bars on the wings (like the "Suaiban" Pigeon in Mr. Easton's work). Some are too light, others too dark, but by judicious matching good coloured birds may be bred from them. They appear to fly with the greatest ease, the air in their crops no doubt sustaining them, as they are very light.—ALFRED HEATH, *Cobne*.

FOUL BROOD.

I FREELY accept Mr. Lowe's explanation in the spirit in which I presume it to be tendered, but at the same time beg most emphatically to disclaim having indulged in any "ungenerous insinuations." I simply stated what Mr. Lowe himself admits to have been the fact, and I had then no means of knowing what, however, I am quite willing to believe—that the numerous misstatements of which I complained arose entirely from inadvertence and defects of memory. Such being the case, I have much pleasure in offering to shake hands over our little difference, and shall be but too glad to benefit by Mr. Lowe's able assistance in the cause of apiculture. I may add that I seek only the truth in these discussions, and am perfectly ready to abandon all or any of my opinions the moment I see cause to believe them incorrect.

Thanks also to my friend the Hampshire peacemaker, I can take a few "raps on the side" as well as any man, when the said "raps" are fairly laid on; neither am I prone to be thin-skinned if the righteous smite me friendly and reprove me; but if their precious balms break my head, may I not rub my pate and cry "hands off!" for the future?

Allowing, therefore, the dust of our skirmish to subside, let us see how the question really stands between us. Following all modern authorities on the subject and being fully borne out by my own experience, I have described foul brood as a highly contagious disease, the radical cure of which is extremely difficult and uncertain, since infection may be communicated by the combs, the honey, and the hive which has contained a diseased colony, and even by the

bees themselves so long as they retain any of the honey which they have taken with them. On the other hand, Mr. Lowe maintains, as I understand, that foul brood is no disease whatever, being merely another name for chilled brood, which he asserts is never removed by bees and consequently must remain a permanent evil in whatever hive it is unfortunately found. He therefore follows the old writers in assuring us that complete excision of the affected parts is sufficient to work an effectual cure, and condemns as unnecessary the various precautions which have been more recently advocated with the view of eradicating an infectious virus which he does not believe to exist.

I imagine that my experiment described in page 342, may have induced Mr. Lowe somewhat to modify his views with regard to chilled brood and its assumed immobility by bees; but as he seems to object to the comb being new, I may remark that the combs were also new in the case of the dozen hours' delay in a warm kitchen, which at the time he so severely reprobated, and, that I have never found bees more reluctant to expel chilled brood from old combs than from new ones.

That foul brood when fully developed is really an extremely virulent disease and by no means amenable to the old-fashioned process of simple excision, is sufficiently proved by Mr. Shearer's narrative in page 182. If, however, it be objected that in this case the excision might not have been complete, I must fall back on my own experience during the past summer, in which, I found that even driving the bees into a clean hive, furnished only with a few empty and pure combs, was insufficient of itself to effect a thorough cure, unless supplemented by three or four days of what has been called penal discipline and inanition in an intermediate-hive. Here, also, let me reply to the query with which "INQUIRER" concludes his letter in page 383. Foul brood has been submitted to microscopic investigation, and apparently with very remarkable results. I am reluctant to forestall, even in the slightest degree, the report of the gentleman who has so kindly undertaken the task, and am equally unwilling to theorise in advance of facts which are still awaiting verification; but this much I may say, that the revelations of the microscope appear to afford a clue to the means by which this pestilential disease becomes epidemic, and explain at the same time why simple excision may frequently work an apparent and occasionally even a radical cure in recent cases, whilst, where the disease is of long standing it becomes so virulent as fully to warrant the doubt expressed by Dzierzoz, as to the possibility of curing it by any process that can be devised.

An instance has recently been brought under my notice by a valued correspondent in the North, which countenances the suspicion that an overwhelming quantity of chilled brood may, under exceptional circumstances, degenerate into actual foul brood, just as an ordinary cold in the human subject may occasionally, although rarely, be developed into malignant fever. This may of course be, as I am inclined to fancy it is, a mere coincidence, and the bees may have imported the infection from some unsuspected source; still I deem it right to mention it, and it may be taken for what it is worth. My own experience undoubtedly tends, as I have before stated, to negative the hypothesis that foul brood and chilled brood are in any wise identical, nor is it countenanced by the best authorities to which I have access. Unlike Mr. Lowe, I do not dismiss with a cursory glance, but on the contrary am disposed to give due weight to what authors whom I find reliable in other respects have written as the results of their own observations on the diseases of bees. Dzierzoz, who stands pre-eminent as the first scientific and practical apiarian in the world, must have had the most extensive experience of a disease which he estimates to have cost him in one season the loss of five hundred colonies, and, I for one, should be slow to doubt, much less to ridicule, the conclusions of so competent and reliable an observer. On the otherside of the Atlantic we have Mr. Quinby, one of the ablest of the old school of apiarians. Few can rise from a perusal of his work without the conviction that he is an honest and painstaking observer, and, speaking for myself, I cannot but deem him a competent authority upon a disease by which he has lost as many as a hundred stocks in a single year. Let me, then, recite the conclusion at which he arrives after a careful consideration of the suggestion which reach: d

him from various quarters that foul brood was entirely the result of chill:—"To me, the cause assigned appears inadequate to produce all the results with the larvae. After close patient observation of fifteen years, I have never yet been wholly satisfied that any one instance among my bees has been thus produced."—A DEVONSHIRE BEE-KEEPER.

POLLEN-GATHERING.

ALL the bees about here (Spalding) have been unusually active with pollen lately. I trace it to blossom of coleseed, of which there is some at no great distance. They even forsake Michaelmas Daisy, which I have observed hitherto as their most favourite plant at this season for it. The idea in the JOURNAL OF HORTICULTURE that it may be from fuchsias I consider quite erroneous: I have as many of them as most persons in my garden, but never saw a honey bee at them yet. Some of the wild bees attack them, and some bore holes in the tube below the calyx for the purpose, but the structure of the honey bee's organs renders this impossible, and it is not possible to reach the honey without so doing. I notice another thing regarding honey-bearing flowers: many which are fruitful in honey in one locality secrete next to none in some other places, to say nothing of the influence of weather.—G. F. B.—Oct. 30.

[My bees were then incessant in their attention to the fuchsias, from which they collect abundance of light-coloured pollen, and extract honey from the punctures, made, I believe, by humble bees, at the base of every flower.—A DEVONSHIRE BEE-KEEPER.]

FOUL BROOD AND LIGURIAN BEES.

I THINK I shall have little difficulty in proving to "INQUIRER'S" satisfaction that he is as much mistaken in attributing foul brood to the introduction of the Ligurians, as he is in anticipating any outpourings of wrath on his head on account of the suggestion, which is after all scarcely so whimsical as that of the American who connected it with the potato disease, and declared that, "Since the potato rot commenced I have lost one-fourth of my stocks annually by this disease."

In the first place, I may repeat what I have before stated—that I have no doubt of foul brood having been first introduced into my apiary by the use of infected combs taken from defunct hives of common bees, and that it has been quite as prevalent and fatal among my black bees as among the Ligurians. Mr. George Fox's Italian stock came from my apiary, and doubtless carried the seeds of the disease with it, although of course, perfectly unknown to me at the time.

"INQUIRER" is also mistaken in believing that Dr. Bevan is silent on the subject, which is in point of fact referred to by him, although under another name. He will also find that it is noticed by Schirach, Bonner, Dunbar, and Huish, all of whom probably lived and died before the introduction of exotic bees was ever dreamt of. In America Mr. Quinby lost as many as a hundred stocks in one year from foul brood, long before the Ligurians were known on that continent; whilst in Silesia Dzierzon's apiary was reduced to ten stocks, and he estimates his loss from this malady at over five hundred colonies during 1848, just five years before he made the acquaintance of the Italian race of honey bees which he has since done so much to render popular.

In conclusion, I commend to "INQUIRER'S" perusal the following appeal recently made on behalf of some unfortunate dwellers in a part of Germany, to which the Ligurians do not appear to have penetrated. It proves at any rate, that the evils of foul brood have been by no means exaggerated by—A DEVONSHIRE BEE-KEEPER.

"FOUL BROOD."

"We—I speak of most bee-keepers of the Guten Society—had in spite of the miserable summer of 1862 and the winter 1862-63, likewise most unfavourable to them, brought our bees tolerably well through the winter. Stocks had greatly decreased in autumn, owing to the 1 ss men rain, cold, &c., but especially from leaving off breeding too early. We

were looking forward to the new year with apprehension; but to our great delight the blossoms of trees and rapeseed gave so much honey, that in spite of cold nights the stocks strengthened themselves visibly. In the middle of May most hives (we use Dzierzon-hives, straw hives, and wooden boxes), were filled with brood and bees. Suddenly the stocks relax in their accustomed activity—notwithstanding the rich pasture they fly but little. What is the matter? The hives are opened, and behold, we find foul brood, of which until then we knew only the name. Of one hundred maggots, three, five, ten, twenty, sometimes even ninety, had grown rotten. Most of the stocks were therefore shifted into other hives at the beginning of July. With some the fasting cure was employed, others were brought into new hives without employing it, and of others the combs were cut as far as the pure sealed honey. And what is the result up to this time? Most stocks are again diseased. There is, however, this difference, that it is no longer the maggots but the nymphs that die. With other stocks neither dead maggots nor dead nymphs are found. The brood, however, is very irregular; regularly sealed combs are scarcely to be found. It must also be remarked that most of the stocks, which were shifted into other hives swarmed out in the beginning of August. These are our sad experiences. Without advice we now stand by our stocks and see them perish, unable to help them. And what will most of our bee-keepers do when the last bee hums to them the far-well-song? They will "throw the gun into the corn."*

"In bee-books much is indeed written on foul brood, and as to what is to be done to remedy this evil; but the end of the song is almost always, "Destroy the stocks and procure new ones!" But who likes to adopt this means? Many of our bee-keepers have deprived themselves to get together the little sum required to procure their stocks; and now, destroy them!—horrible thought!

"And now, gentlemen, has no sure means been recently discovered of remedying this evil? It is the duty of man to assist his fellow man at least with advice. Do not allow so many bee-keepers any longer to pass sleepless nights and days of grief. Many a poor man loses by this disease twenty, fifty, a hundred and even two hundred thalers,† and that is much for him. Dzierzon, Von Berlepsch, Kleine and other honoured gentlemen, give us some advice if there be yet a means of clearing foul-breeding stocks.—N."

MALE WASPS.

In one of your late Numbers you mentioned that some of the male wasps had stings; I must beg to differ in toto from this. For the last few years I have examined scores—nay, hundreds, and never yet found a male with a sting. I have often nests brought to me with scores of both males and queens in them, and have frequently caused much amusement by taking up the wasps (males of course) in my hand with the most perfect impunity, pretending they never stung me. They are so readily distinguished from the ordinary wasps by their long horns and long bodies that I have never any fear of laying hold of the "enemy," or else "woe betide me." I think, therefore, you are quite mistaken in supposing that the male wasp has any sting whatever. We all know that the drone bee has not.—RYFURNE.

* This means that they will give up bee-keeping altogether.

† The Prussian thaler is nearly equal to 3s. sterling.

OUR LETTER BOX.

BOOK ON POULTRY (M. C.).—No book will teach you "every particular, so as to make poultry profitable." You can have "The Poultry Book for the Many" free by post from our office for eight postage stamps. That will give you all the general information. Management, economy in feeding, and the use of your own good sense will be the other chief aids to success. When any difficulty occurs you can have further information through this Journal.

DYEING MOSS GREEN (O. W. D.).—We have been told that this is done by soaking perfectly dead moss in a warm solution of verdigris in distilled vinegar. Perhaps some of our readers will oblige us by decisive information on this subject.

HERON'S PLUME (L. E.).—"The feathers which constituted 'The Heron's Plume,' were the fine and descending feathers of the bird, especially those above the wings.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 47.2°, and its night temperature 34.1°. The greatest heat was 60°, on the 28th, 1828; and the lowest cold, 14°, on the 30th, 1856. The greatest fall of rain was 1.21 inch.

ORCHARD-HOUSES AND PEACH-HOUSES.

HAVE occasionally observed in articles written by your contributors, describing their visits to great gardens and good gardeners, that the latter have spoken

disparagingly of orchard-houses as compared with Peach-houses, and it may not generally be known that they are to a certain extent quite correct in their

opinion. The truth is that where the produce of a fruit garden is alone thought of, and not the pleasure of cultivating fruit, the orchard-house is out of place unless it be in situations where such fruits as Cherries, Pears, and Plums do not succeed on walls. In such places houses for them erected in the kitchen garden would be found of great use. In a first-class well-appointed garden, with Peach-houses and fine walls, the owner of which is either an absentee or fully engaged in political or mercantile life, knowing nothing and caring nothing for fruit-culture if his table is well supplied, an orchard-house is not wanted, and a gardener would not act with judgment in recommending one. But if a nobleman or gentleman interested in fruit-culture, and wishing for one of these most agreeable structures for a promenade, as well as the pleasure of seeing fruit in all its stages of growth, asked his gardener's advice as to the propriety of building one, he would, even if he had numerous Peach-houses, act well to promote it. The late (but one) Lord Braybrooke was the only nobleman in my experience who felt much interest in orchard-house culture. He had a large house built at Audley End somewhere about the year 1852-3, and I remember hearing from his own lips the great pleasure he had derived from it in his old age and declining health, for he seldom passed a day without a promenade in his orchard-house. I can fully understand this, for during the stormy weather we have had lately I have found my daily walk in a house 100 feet long, the thermometer at 60°, always most agreeable; for the fruit-buds of Peaches and Apricots are already commencing to swell, and one seems to picture the trees covered with their gay flowers.

With respect to the produce given by a Peach-house, the trees trained to trellises in the usual way, and an orchard-house with full-grown trees in 15 and 18-inch pots, I have the past season had a good opportunity of making some calculation. It may possibly interest some of your readers.

From one of my large houses 100 feet long and about 24 feet wide, I gathered in the past season as nearly as I could calculate about twenty bushels of Peaches, Nectarines, and Apricots from two hundred trees, some planted in the ground, but the majority in pots (some in 15 and 18-inch pots). I found on measuring the fruit

of fair-sized Peaches that twenty-five would fill a half-peck measure heaped in the usual way of measuring fruit; and that the large trees, now from ten to twelve years old and upwards, produced from four to five dozen—in round numbers a peck each. This would have given, if all the trees had been of the same age and growth, the large aggregate of fifty bushels; but many of the trees are young, and some gave only from one to two dozen each.

To amuse myself, I imagined my span-roofed house divided and formed into a lean-to house 200 feet long, carrying a trellis under the glass 10 feet wide, allowing a little space at bottom and top which the trees would not probably cover. This would give 2000 square feet of trellis. It has, I think, been stated somewhere that a square foot of wall to which a Peach tree is trained should carry twelve full-sized Peaches. This is a mistake: six full-sized Peaches are as many as can be grown on a square foot either of trellis or wall. To ascertain this without any calculation, a square foot should be formed with four pieces of deal nailed together, and then placed on a Peach tree full of fruit nailed to a wall. Six full-sized Peaches will be found to occupy the square foot, leaving only a sufficient space between each for full exposure to sun and air. We can thus easily calculate the number of Peaches (when the crop is good and regular), that a lean-to Peach-house 200 feet long, with the trees trained to a trellis should give—viz., 12,000 Peaches, amounting, when measured 50 to a peck, to 60 bushels.

We must now take a span-roofed orchard-house 100 feet long and 24 feet wide and calculate its produce. In a house of these dimensions 180 full-sized Peach trees may be cultivated, and in a large house like this trees on stems from 2 to 3 feet in height are the most eligible. If well cultivated they may, in the course of two or three years, be transferred to their permanent large-sized pots, 18 inches in diameter. They soon form fruitful round-headed trees, and bear large crops. When in full bearing each tree should give from four to five dozen of full-sized Peaches—for the sake of round numbers we will say fifty. One hundred and eighty trees will thus give forty-five bushels, or fifteen bushels less than a trellised house with the same quantity of glass. I have purposely made this low calculation. The advantages of this trellised house are the regular exposure of every fruit to the sun, and consequently a greater increase in colour, making the fruit better adapted for market; so that where they are grown for profit, or merely to supply large establishments, the trellised house is the most advantageous: therefore a good gardener who well understands the training and management of Peach trees is quite right in adhering to the system. Much labour and much skill are required in the management of a Peach-house, and there is but little pleasure in it for the amateur—a promenade under a thickly covered trellis, with the fruit only to be seen imperfectly from below, is not agreeable.

We must now consider the advantages of the orchard-

house as a mode of Peach-culture. I repeat that it is a structure eminently adapted to give much pleasure to those who love gardening, and who enter into the spirit of fruit-culture; for the trees, growing to a certain extent in their natural state without the formality of training, remind one of more favoured climates. I have, however, a strong opinion that with many persons the Peach tree trained against a wall is its natural state, so much is it associated with our gardening ideas. We walk in an orchard of Peach trees, we enjoy the blossoming season, we see every fruit, and if we have time and skill we assist our gardener by taking a few trees under our especial charge, pruning and pinching them in friendly competition with him. This is the sort of intercourse that should take place between the gardener and his employer, leading to a very happy state of things, and widely different from the old-fashioned reserve which with too many used to make a gardener fear to make his employer too wise.

As I have stated in the commencement of this article, orchard-houses are not required in first-class gardens that are favoured with a good soil and climate, and which are cultivated merely for their produce—such as the Royal Gardens, Frogmore, for instance; but in first-class gardens not so highly favoured by climate, and where Apricots, Pears, Plums, and Cherries trained to walls too often fail from the effects of spring frosts, they may be made most useful adjuncts to the kitchen garden. Mr. Thomson, of the Dalkeith Gardens, cultivates Pears in pots with great success. He has now upwards of a hundred trees in pots, and finds their fruit always excellent. So that in gardens in cool climates, where there are Peach and Nectarine houses heated in the usual manner, but where the above varieties of fruits not requiring artificial heat are wanted, strongly built but cheap houses might be erected in the kitchen garden for their culture. The finer kinds of Cherries amply repay the cultivator of them in such houses, as do Plums, and above all Apricots, for of all wall trees Apricots (the finer varieties), are the most tiresome to the gardener. It is very rare to find a wall planted with Apricot trees in a well-furnished state; for after a few years large branches die, and those left are too rigid to be bent so as to fill the vacancies: consequently the good gardener feels constant annoyance at seeing what he cannot remedy.

All this may be avoided by having a span-roofed Apricot-house: it should not be small, but 20 or 24 feet wide and 12 feet high. But few gardeners as yet know what can be done in the culture of Apricots in pots in well-ventilated houses. Pot-culture is by far the preferable mode. When planted in the borders under glass they will grow rampantly and make long shoots without blossom-buds; whereas in pots they make short-jointed shoots, which are generally full of blossom-buds. The soil they require is a tenacious loam made very firm by ramming it down when partially dry, at the time the trees are top-dressed in autumn.

It is but recently that I have been fully impressed with the agreeability and perfect success of pot-culture for Apricots. Some of my trees in 18-inch pots are ten or more years old; and those on stems from 2 to 3 feet in height are models of perfection in culture. Their heads, from their shoots having been pinched in during the summer, are round and sturdy as a pollard Oak, every shoot of last summer's growth being a mass of blossom-buds. If Apricots are cultivated in houses of the height I have mentioned entirely appropriated to their culture, I should recommend them all to be grown as low half-standards, with two to three-foot stems; they will then in the course of a few years form round heads full of health and fertility. So averse are they to having their roots disturbed, that I have known all the blossoms from a large number of trees drop off without setting their fruit, only because they were top-dressed after Christmas. For this reason I have my trees operated upon in October, and but a small quantity of the old soil—not more than 2 inches in depth—taken out.

They seem to succeed so well in a soil that is firm—I may say hard—that in places where only a sandy loam can be had, it must be rammed down most firmly; and I am not yet quite certain that the best method of treating Apricot trees in pots growing in such a soil is, not to take out the soil and top-dress in autumn, but to allow the trees to remain in the hard and dry soil all the winter, giving them some

water about the middle of February if mild; and after they have blossomed and set their fruit, and when it is about the size of a small horse bean, to scrape off the surface soil an inch in depth, so as not to disturb the young fibrous roots, and give them a rich surface-dressing, to be repeated during the summer as soon as it has subsided by the watering. This method was fully carried out here the past season, and nothing could be more satisfactory. My Apricots were abundant and most delicious. Writing of watering reminds me that it has been made to a certain extent the bugbear of the pot-culture of fruit trees. If every cultivator would take a lesson in watering from the Crystal Palace, and have a cistern a little elevated, and gutta-percha tubing, watering potted trees would cease to be a formidable operation.

As far as I can see into the future, it appears highly probable that the attempt to grow choice fruit in the north otherwise than in orchard-houses will be abandoned, and the neighbourhood of such rich and populous towns as Newcastle, for instance, will abound in houses appropriated to the culture of fruit trees; and I repeat, that even in the more favoured parts of our island as regard climate, in gardens with vineries and Peach-houses in abundance, the Apricot-house and the Cherry-house will be found most useful, and give a gardener much comfort. I must not, however, omit the Apple. Only those who have seen specimens of the fine American Apples, grown on small trees in pots in an orchard-house, can have an idea of their value as dessert fruit; their size and beauty, as well as the nature of their flesh, always tender, juicy, and rich, render them almost unique. I have at this moment specimens of the Melon Apple, part of the produce (eighteen in number) of a little tree grafted on the Paradise stock, growing in an 11-inch pot, measuring upwards of 12 inches in circumference, and perfectly beautiful. The Northern Spy often exceeds this in size, and the Newtown Pippin grown under glass is a superior fruit to those imported. It is only the increased temperature and dryness of the climate under glass that gives those Apples their remarkable beauty and excellence; but little care is required in their cultivation, and the roughest glass-roofed shed will serve for an Apple-tree house.

Innovations in Horticulture, and its sister science Agriculture, are always resisted, and however sound and beneficial, make but slow progress. In this respect how unlike any good mechanical invention, which is at once seized upon and spread over the face of the world! The orchard-house idea was first promulgated in 1851; and although it made its way among amateurs, many of whom having skill and perseverance had great success, yet many failed from thinking that fruit trees could be cultivated in common greenhouses ventilated in the usual inefficient manner. Its great opponents were, however, a class of men who set themselves up as oracles in gardening—men with more words than wisdom. I used formerly to hear persons of this class say, "Oh, this is all wretched nonsense, no tree can be kept in health in a pot more than two years." After twelve years of close observation I am thoroughly convinced that everything appertaining to orchard-house culture is sound, and that those who wish to find pleasure in the cultivation of fruit cannot find any gardening pursuit more agreeable than its culture under glass.—T. R.

ANOTHER WORD ON STRAWBERRIES.

I FANCY your correspondent who signs himself "J.B.C.P.," in the Journal of November 10th, in his strictures on the mode of growing Strawberries as practised here, appears annoyed at an expression used by me in an article contributed to your Journal of October the 20th, in which the word "barbarous" is applied to the indiscriminate removal of the leaves from the Strawberry plants previous to the winter setting in. Your correspondent, in refutation of my practice of allowing a great portion of the leaves to remain on the plants until spring, adopts a rough and ready way of manipulation, by the introduction of a novel instrument for that purpose in lieu of a knife, in the shape of a scythe. If, therefore, he considers this instrument so very effective, why not apply it in mowing off all the decayed or spent

leaves and stems from the perennial plants, in his garden in the autumn in like manner, and let his newly-introduced kitchen-garden implement at once supply the place, wherever practicable, of the knife?

Your contributor is at perfect liberty to follow his own course, and he will say the same to me, as regards that with which I am perfectly satisfied. However, for the benefit of your general readers I will endeavour to explain my reason for allowing a great portion of the old leaves to remain during the cold winter months. If, in the early autumn, or when the fruit is all gathered, I were to denude my plants, wisely provided with their coming winter clothing, one of these consequences would arise—either the plants would be insecurely protected against cutting winds and frosts, or Nature must make an unusual effort to reproduce leaves at a period when the plant should be partially at rest, at the manifest expenditure of energy and to the impoverishment of the soil.

It appears similar to me to the shearing-off the wool from a sheep in autumn to compel Nature to supply it with fresh covering from the wintery blast.

Unquestionably fresh leaves would make their appearance and attain some little growth; but does your correspondent believe that these newly-formed ones would be so likely to contend against the storms and frosts of our ordinary winters as the old and well-ripened ones? With regard to his gathering nearly half a bushel at a time from a quarter of an acre of land, for nearly three weeks, planted with Keens' Seedling, I do not consider that so very extraordinary a produce, being by no means equal to what I gathered proportionably from beds of the same variety, and the fruit equally fine. The plants to-day (November 19th), are many of them 2½ feet in diameter.—QUINTIN READ, *Biddulph*.

EXHIBITING ROSES.

HAVING lately been thrown much amongst Rose-growers and Rose-exhibitors, and had a good deal of conversation on the subject of Roses and Rose-showing, I think it may serve the cause we have so much desire to advance if an opening is made for the ventilation of some matters which have in one way or another been brought under the notice of the Rose-loving public during the past few weeks. I do not expect that we shall ever arrive at agreement, either as to the character of Roses or the method of exhibiting; but there are some common-sense points of view, at least so they seem to me, that ought not to be overlooked, and, if possible, agreement come to as to the course to be adopted. Having had some experience also in Rose-judging for some years, I may, perhaps, be considered as having some little claim to obtain a hearing, while the fact of my not being an exhibitor may clear me from the notion of any partiality or one-sidedness in the matter; my sole desire, as far as I know myself, being to advance the culture of a flower which all alike have crowned a queen.

I. WHAT IS A TRUSS?—It may seem somewhat strange that so simple a question should, even now, after so many years of Rose exhibitions still remain a disputed point; but so it is. A Rose throws up, according to its character and habit, shoots that bear sometimes one, at others two, three, four, or five buds as the case may be. Now the question I take to be this—Is the shoot to be shown as it grows, with its full-blown flowers and buds? or is it lawful to disbud—that is, to remove some of these buds for the purpose of throwing vigour into the remaining one or not? and is a shoot so disbudded to be considered as a truss? Now the object for which this is done is, I suppose, to obtain greater size, and this mania for size is likely to spoil our Rose taste. A Rose which is naturally of a medium size can never be exhibited as large, unless by the loss of refinement; and coarseness, I think, is fatal to a Rose. What is the use of a flower as large as a breakfast-saucer if there be no quality about it? A truss, then, I should consider the natural production of the shoot, and that disbudding ought not to be allowed. If, however, this do not meet the views and wishes of the Rose-growing fraternity, I would then say, "Make rules as to what a truss is, and adhere to them," for the present system is manifestly unfair—viz., that some should exhibit them *au naturel*, while others have by copious

disbudding obtained size, which I know with some judges supersedes quality. It is said that if you do this you must examine each Rose, and pull it out of its tube, &c., in order to see whether it is fairly exhibited. Not so. It might be and would be desirable to examine one or two in each stand; but of this I am persuaded, if a man wishes to be dishonest as an exhibitor no rules will stop him. Even during the past season I saw flowers, not Roses, exhibited, of which I am morally certain not one was grown by the person in whose name they were put up. There was no proof to the contrary, and so the matter was passed by.

II. HOW MANY TRUSSES SHOULD BE SHOWN?—This opens out the question of trebles, and number of blooms also. If the rule with regard to disbudding were maintained I would discard trebles *in toto*; it entails so much labour on the Judges that, unless they adopt the French plan of allowing one whole day for the adjudication, I do not see how it is to be done. The place of exhibition is rarely cleared before half-past ten o'clock, and at twelve, both at the Crystal Palace and Kensington, the public are to be admitted—yet in that hour and a half some Judges have to decide on the merits of perhaps eighteen hundred Roses! Moreover, too frequently one good flower is obliged to carry two indifferent ones on its back, or to hide them, rather, in its ample folds; to obtain nearly three hundred good Roses taxing even the ingenuity of our largest growers. Then I would do away with the 96 Class altogether, and make fifty the highest, giving more prizes for smaller numbers. Rose-growing is now so extensive that there need be no fear of not having the stages filled—nay, I think they would be better filled if so many flowers were not required. Who would not rather see forty-eight really good flowers than twice the number of indifferent ones?

III. IN WHAT MANNER OUGHT THEY TO BE SHOWN?—"Oh! with moss, of course," exclaims every looker-on. Softly, gentlemen, if you please. Why so? What reason, except some sentimental one, can be given for it? If moss be fit for Roses, why not for Dahlias? What is the object to be gained by a Rose show? Surely the seeing of the best Roses. Now, I verily believe this moss hides a multitude of sins; and a bed of fresh, bright-looking, green moss is quite a foil to many a piece of blackened and spotted foliage, while it is a manifest injustice to many a Rose-grower. Often, I am convinced, the excellence and smoothness of the moss catches the eye of a judge, and first impressions very often do a great deal, so that a person who lives in the neighbourhood of Windsor or Epping, or in any wooded county, has a most appreciable advantage over those who do not. Why, if I were to run the risk of breaking my neck for a week in this neighbourhood, I could never find a bit of moss that was worth looking at, and, consequently, could never hope to put up a stand satisfactorily; and then there is another most serious drawback—viz., the expense of transit that it entails. Boxes must be carried already prepared for exhibition; and with the moss in a damp state, which it must be, the weight is considerably increased; so that all idea of gaining anything by the prizes is taken away. Mr. Hedge's gardener told me the other day, that when he took his Roses to the Birmingham Show it cost £12, and, although he took all the first prizes, he only obtained £14; whereas, if they were exhibited as Dahlias are, the boxes could be easily carried, and the tender mercies of the guards and porters could be dispensed with. There would then be no need for the gardener to sit in the break-van to mount guard over his treasures, as I know to have been done, and the break-neck work of setting them up at the Palace would be avoided. Moreover, we should be much more likely to see that all was fair in the exhibiting, and the quality and character of the foliage would be more conspicuous. If "good wine needs no bush," I am quite sure the Rose needs no meretricious ornament to set her off. The addition of foliage is fatal, and so would I make the addition of moss. Nothing but the Rose *pur et simple*.

IV. OUGHT THE CLASSES TO BE SEPARATED?—A good deal has been said lately about the necessity of doing this. With both hands I protest against it. Have the advocates of it ever really seen a box of Moss Roses worth looking at? I never have, and a box of Teas is almost as poor; and although we have great brilliancy of colour in the Hybrid Perpetuals, yet I am sure it would be ruin to them to show

them by themselves. Let it be remembered, that they, various and beautiful as they are, are after all only shades of red, from very faint blush up to brilliant and dark crimson; for Madame Rivers, and Caroline de Sansal, and even Mademoiselle Bonnaire, are not white Roses, and Louise Darzins is more of a Noisette, and will never make an exhibition Rose. And then to exclude the buffs and yellows amongst the Teas and Noisettes would, I am sure, be a most unwise step—they help so to relieve the boxes, that I cannot conceive a stand would look well without Gloire de Dijon, Céline Forestier, or Triomphe de Rennes. At the same time, I do not think undue preference should be given by judges to those stands where these appear. It is not in the south of England much more difficult to grow a Tea Rose than a Hybrid Perpetual, and yet often I fancy there is an impression that of five or six Roses from amongst the Teas and Noisettes, the stand which is so furnished ought, whatever be the merit of the flowers, to have the preference. It strikes me that this is wrong, and that the judgment ought to be irrespective of the classes, simply on the merits, individual merits, of the flowers shown.

V. ARE FANCY CLASSES DESIRABLE?—Let me explain my meaning:—such a prize, for instance, as one for a single truss. To take off a £2 prize for one Jules Margottin, is, no doubt, a very nice thing; but is it not calculated to mislead? and might not the funds be better employed? These bouquets of Roses, unless some definite notion of the terms of adjudication be given, must continue to be what they have proved—a source of perplexity to judges, and of annoyance to exhibitors. At the Crystal Palace the Judges were told that the vase in which it was exhibited had nothing to do with the merit of the bouquet; the quality of the flowers and the taste of the arrangement were the points to be considered; hence the prize was given to a very fine bouquet of very fine Roses. At Kensington, on the other hand, the quality of the Roses seems never to have been considered. The first prize was awarded to one of Mr. March's stands, which contained corals, &c., and a few very poor specimens of Roses, and was avowedly given because of the taste displayed in the stand, which taste I considered very questionable, my notions on that point tending towards severe simplicity, and abhorring all cockneyism.

I have thus gone over the various points connected with Rose-exhibiting that have suggested themselves to me. The opinions are my own, although in most of them I am strengthened by the opinion of some of the most successful exhibitors we have, both amongst nurserymen and amateurs, and I shall be only too glad if they are the means of opening up a discussion on the points. The more such subjects are discussed, if done in a friendly spirit, the more I am persuaded will good be effected; and let us hope that Rose-showing may be in fashion even more than it has hitherto been. Not a grower in the kingdom but has to tell of very large quantities being sold this autumn, and this we must hope is suggestive of an increased interest in the loveliest and most generally loved of all flowers.—D., *Deal*.

DO LEAVES ABSORB MOISTURE FROM THE ATMOSPHERE?

YOUR correspondent "S. L. G., Cornwall," asks for more information on this subject.

The question, as will be seen on referring to the works of physiologists, is a disputed one; some contending that leaves do, and others that they do not, absorb atmospheric moisture. Bonnet, who paid much attention to this subject, found that some plants absorb moisture either by the upper or under surface of the leaf indifferently, but that some absorb more powerfully by one surface than the other. He found that the leaves of the Kidney Bean and Cabbage, with some other vegetables, retained their verdure equally long whichever side was deprived of the power of absorption, whilst the Marvel of Peru and others lost their life soonest when the upper surface was prevented from absorbing; and, on the other hand, that, of many trees and shrubs, the leaves soon died when absorption by the under surface was prevented. These experiments, however, cannot be considered conclusive that leaves absorb moisture, for by preventing absorption he would hinder evaporation in some cases, and respiration in

others. Dr. Lindley agrees with Bonnet, but many eminent men advance in proof of the non-absorbing power of leaves that if they be made to float on coloured infusions no colouring matter whatever enters them. I will give proof sufficient, I think, to convince even the most sceptical that leaves in a healthy condition do possess an absorbent power; and I hope to show, when roots are disposed of, that it is by no means uncommon for leaves to absorb nutriment from the atmosphere irrespective of that collected by the spongioles.

If a plant be allowed to become dry at the root the leaves will flag from want of moisture. They emit more water than the roots afford them. Syringe the plant whilst under the same amount of light, and the leaves regain their original freshness. I am aware, if the plant were placed in a moister atmosphere and shaded from light so as to prevent too hasty evaporation, that the leaves would become fresh. But how could the leaves repair the waste consequent on evaporation if they did not absorb moisture? That they obtain moisture from some source is manifest, but whether from the atmosphere by absorption or from the dry soil through the spongioles is a matter of doubt. If they obtain the moisture through the spongioles it is evident that syringing the plant whilst under the influence of light hinders evaporation. De Candolle assigns light alone as the cause of evaporation, but dryness has quite as much to do with the evaporation of water by leaves, as in the case of plants in rooms dark but dry. If light be the cause of evaporation it is evident we do not cause darkness by syringing the plant's leaves, therefore evaporation goes on: the roots do not pump up more moisture, and yet the leaves become fresh. We, however, will not syringe a drooping plant, nor place it in a moister atmosphere, nor shade it from light, but let Nature take her course. There shall be no syringing of the house, the temperature shall not be altered, and the degree of humidity, as indicated by a dry and wet bulb thermometer, shall remain the same during the night as during the presence of light. Examining the plant at midnight the leaves still droop. There is no moisture in the atmosphere, and the darkness does not prevent evaporation. Morning finds it no better. We will then syringe it, prevent water reaching the roots, and keep it from light, sprinkling every available surface with water, shutting up the house, and syringing the plant again before dark, also allowing the temperature to fall considerably during the night so as to favour condensation. The result will be that the leaves will be fresh in the morning. Further: during hot dry weather in summer when the ground is little short of dry dust, what gives the flagging leaves by day their freshness in the morning? Not because they inhaled oxygen and liberated carbonic acid; but because they absorb moisture along with the oxygen, in sufficient quantity to repair the waste of the previous day, again to be exhaled during the day, unless the weather prove cloudy. If, however, the day be sunny the oxygen inhaled during the night is exhaled during the day. This I have on the authority of Saussure. If plants derived no benefit from dews the non-absorbing powers of leaves would be determined; but as all foliage is refreshed by moisture or dew falling on it during the night, the absorbing power of leaves seems to be established. Further: every operation in the cultivation of plants by artificial appliances acts on the principle of moisture being absorbed by leaves at night. The cultivator bedews his plants with water, makes all moist about them, and seeks to rest them by keeping the temperature 15° to 25° less by night than during the day.

Again: let a Gloxinia leaf be detached from the root, it cannot, therefore, obtain any moisture in that way, and expose it to the influence of the sun or light so as to cause evaporation from it until one-fourth its weight is lost from evaporation; then place the footstalk of the leaf (petiole) in a quill filled with oil, so as to prevent absorption through it; next moisten the upper and lower surface of the leaf, and, sticking the quill in moistened silver sand, place a bell-glass over it, and put it in the dark. The leaf regains its freshness, and if we examine the under surface we find it dry, the moisture having been absorbed more quickly by it than by the upper surface, which remains moist or wet. Absorption is, therefore, more rapid by the under than the upper surface of a Gloxinia leaf. A Gloxinia leaf is covered with a quantity of hairs on both sides, every one of which performs no mean office in the vegetable economy, and that office, I

believe, is the absorption of moisture. The pores, or stomata, also absorb moisture, and thus a rootless leaf is enabled to retain its verdure until a callosity is formed and roots are emitted. A leaf of the *Cineraria*, *Begonia*, or *Vine*, taken in a flagging state and placed in a close, moist, and shaded atmosphere, regains the fulness of its parts through its stomata while its leafstalk is deprived of the power of absorption. Moreover, we have a *Calceolaria* cutting and we will allow it to flag. If in that state the bottom of the stem is placed in a vessel containing oil, the leaves being moistened, and if it is then placed on moist sand with a bell-glass over it in a shaded place, the leaves not only absorb moisture sufficient to fill their empty cells, but that of the stem as well.—G. ABBEY.

WINTERING BEDDING PLANTS.

The following is the plan I prefer to many:—

For instance, the *Geraniums*: I put three cuttings into a 60-sized pot, in a compost of leaf mould, loam, and a sprinkling of silver sand, the pots being previously well drained. They are then placed in brick pits with lights over them. After they are struck they are fully exposed to all the light and air possible; but in case of heavy rains the lights are then replaced. I may add that they occupy the same pots through the winter, and are stored away in the greenhouse as closely as will permit a current of air passing freely between them. The supply of water required is very limited indeed until the days lengthen, when they will require a somewhat larger supply. About the middle of March I dig out all the *Celery-trenches* that are required for the season, and, these being 4 feet wide, in the bottom I place about 4 inches of leaf mould and road sand mixed together. I then fork it in lightly with a little of the common garden soil for the reception of the stock of *Geraniums*, which are planted about 9 inches from plant to plant in the rows, the rows being about the same distance asunder. Prior to dividing them I give them a thorough good soaking of water, after which we can perform the operation without the least injury or check to either of the plants. They are sheltered with straw covers, such as are used at *Putteridge Bury*, and so often described by Mr. Fish.

After they are all turned out there are about two thousand pots at command, which are then all washed clean preparatory to the potting of such as *Verbenas*, *Lobelias*, and a great variety of the more tender kinds of plants. The *Calceolarias* are never troubled with either pots or artificial heat: they are treated precisely the same as we have done them before at *Putteridge Bury* under the directions of Mr. Fish, and we shall be greatly surprised if we lose a dozen out of two thousand plants.

The *Calceolarias* are planted out in the trenches as above mentioned for *Geraniums*. They both do equally well, and by the time you want to plant them out they are fine stocky plants. With the aid of a trowel or small fork we can lift them with as much ball as we like; and after planting them in their respective quarters, the soil being previously well stirred, and finally a good watering, not a leaf of either would be seen to flag.—J. B. C. P.

GRAPES SHRIVELLING WHEN IN BLOOM.—Having seen an article in your *Journal* of March 24th about Grapes shrivelling up when in bloom, I wish to state that I witnessed the same in a large late vine, of which I had charge at a somewhat later date, although in certain parts of the house they set well. Thus, one cane at the end of the house, which was brought down at the top to nearly a level position, sets its bunches well throughout its length. Also, in other parts of the house where the shoots happened to grow up under rafters shaded from the sun, the bunches set and did well; but in this case it was near the top of the house that they did so. In my opinion the well-doing of the Grapes depends upon the position of the canes at their blooming season, or even before it, and after the Grapes are set. The Vines above-mentioned were planted in the usual way in a border in front of the vineries, the border being rich and moist.—D. PRATT, *Gardener to the Hon. D. Plumet.*

HOLLYHOCK FLOWERS BECOME BLACK.

YOUR correspondent, "AN OLD LADY'S," Dahlias would have looked well with my black Hollyhocks. You do not believe that her Dahlias became white, and you may be equally incredulous that we have about fifty Hollyhocks, fine double flowers of all colours, which last year turned black. I let them remain, as I thought they might return to their true colours this year, but again they were all black. Every one that has seen them remarks that the like was never known before.—A SUBSCRIBER FROM THE COMMENCEMENT.

[We never before heard of such a wholesale change of colour. Certainly we have heard that clayey loam, blue vitriol, and iron filings have sometimes changed *Hydrangeas* blue; and also that *Norwood loam*, on account of its large amount of iron, had the same effect. Granting that you have not been deceived, the complete change from many colours to one must depend on something in the soil. It would save a deal of uncertain speculation in many cases if our correspondents would state particularly the nature of their soil and subsoil when advice about plants is asked for. Pray tell us the nature of the soil in which your Hollyhocks have played such fantastic tricks.]

GARDEN BOILERS.

If I had not had the experience of above ten years' experiments amongst the various modes of heating garden structures, I should not now venture to pen a few words upon a subject so important to my brother amateurs.

I have tried various kinds of boilers and various modes of heating them; and as I am also the proprietor of a large establishment where I have steam boilers and hot-water-heating apparatus employed in my business, I may venture to give the result of my experience, and, if needful, warn your readers against some useless outlay. My principal reason for writing at present is that I see a disposition to employ a method of heating water which has the tempting attraction of being apparently the most efficacious. I say apparently, because I know that it is deceptive, not intentionally so, but nevertheless both deceptive and expensive. I allude to what are called tubular boilers. There is no novelty in the idea of heating water in tubes, and it is equally certain that when quite newly erected it is the most economical method of conveying heat to water, but the apparent economy soon vanishes unless extraordinary mechanical arrangements are provided for perpetually keeping the tubes free from soot, which is well known to be a most perfect nonconductor of heat. Many, very many years ago, various ingenious methods of heating the water which is used in large steam boilers were tried, such as passing the pipes through the furnace itself (a fallacy, for it was robbing Peter to pay Paul)—another plan was to use the waste heat between the boiler and the chimney, to heat the water in a pipe or pipes fixed in the flue, which is exactly the principle of the present fashionable tubular boilers. This method was found to act admirably for a short period, but as soon as the pipes became coated with soot, the water actually became cooler instead of hotter, though it passed in the pipes down 40 or 50 feet of a fiery flue; consequently this system was abandoned, until a clever Mr. Green discovered and patented a method of working by mechanical agency a set of sweeping-brushes or scrapers, which are perpetually traversing up and down a set of tubes placed in a flue perpendicularly, exactly like the tubular boilers, and by this means keeping them free from soot. It is only by the perpetual cleaning that these pipes can be kept hot; if the sweeping machine stops, the pipes soon become cold. Your readers will see that the same result must inevitably take place with their tubular boilers. At the outset the new boiler does wonders. It is watched at first by both master and man, but after a while both will have cause to express their disappointment because they cannot make the fire heat the pipes as it did at first, or at any rate without an enormous consumption of fuel, which only succeeds because it manages to touch some small part free of sooty deposit. Now, remember that I do not dispute that tubes are the most economical mode of imparting heat to water, but to do so they require to be kept perfectly clean; and how

can that be done except by mechanical means, kept in motion by machinery? and how few, how very few of us, could or would incur such an expense?

From the above remarks you will agree with me that amateurs must look elsewhere for the great desiderata in a garden boiler—namely, “simplicity and efficiency,” or should I say efficiency and simplicity? for it is difficult to decide which should be put first, both being of such importance. I have reason to believe that the boiler the most simple in construction will in the long run prove the most efficient and decidedly the most economical; such at least has been the result of my own experience and the result of my observations on the successes and failures of my neighbours. Now I will only venture to describe two kinds of boilers which appear to me to be exactly what we all require—exceedingly simple in construction, efficient in action, and economical in working. The first being the oldest shall be described first: it consists simply of two flat oblong cast iron boilers, 2 feet 6 inches long, 2 feet wide, and only 3 inches outside depth, with a flange pipe on each end by which they are connected with each other.

Now the manner in which these are placed secured for them the greatest possible heat, and the plainness of their construction afforded the best chance of their being kept free from soot.

No. 1, fire-box. No. 2, the lower boiler connected with No. 3 by a pipe which is not shown, the flange pipe at one end of No. 2 being the feed, and the upper flange pipe of No. 3 being the flow.

The two boilers are set with their edges resting on fire-brick walls, and the ends placed as shown in the engraving. The heat from the fire passes by the flue 5, 5, 5, 5, under and over both boilers and round one end of each; it also passes under No. 4, which is a separate and independent pan or tank having a sand-bed under it for propagating purposes.

No. 6 is the ash-pit, and No. 7 is a framed iron door, which enables the man to rake out any soot which may accumulate; a damper at the top of the flue regulates the draught. Now this has been working for years, and probably will outlast many of the present generation of boilers. It certainly has not yet been beaten in efficiency, and has the merit of not being particular about the quality of the fuel.

The next is equally simple, but to my mind more efficient, because it economises all the heat by surrounding it with a jacket of water. It is constructed of two plain cylinders, one inside the other with a space of about an inch wide for the water between them. The feed-door is at the top; on the side and at the bottom is a small door to withdraw the ashes. The part above the feed-door may be made to form part of the boiler, or it may be made available to heat a propagating tank as before described. Now a boiler of this description prefers coke, or coke and small coal mixed, but it has this advantage that it does not require feeding so frequently, and it is wonderful to see what a quantity of piping one of

these little boilers will keep hot. In appearance it is not unlike a cannon boiler set on end. I have seen one of these boilers, 3 feet long and 1 foot diameter inside the cylinder, heating 900 feet of piping. The especial advantage of this boiler is, that as long as the fire is burning in any part of the upright cylinder, it heats and causes the water to circulate, so that whether the fire is burning at the bottom or has eaten its way towards the top of the fuel the boiler is in action, and the intensity can be regulated by a damper which is attached to its outlet-flue. These boilers also do not require any brick-setting to fit them up, but I recommend them to be enclosed in some rough covering to economise heat.

I have no intention to recommend any particular boiler-maker, in fact I shall decline to do so, because the proper medium of such communications is through your advertising columns.—W. W.

BLANCHING CELERY.

SEEING lately in your Journal some remarks on different modes of blanching Celery, I am reminded of a plan I saw in Oxfordshire in August last. It was simply placing a common drain-pipe upright, and allowing the plant to grow up through it. My friend, in whose garden I saw it, assured me that he not only had his Celery blanched much better, but also that it was ready for the table much earlier. That the latter is the case I can affirm from my own observation; for the plants I saw growing in the pipes had already grown above the tops of the pipes, while those treated in the ordinary way were not half so high.—A POOR MAN.

A PLEA FOR THE ARBORETUM.

OF late years the importation of trees of foreign growth into this country has certainly been all in one channel—Coniferae. Assuredly the countries whence our many really useful members of this family have been drawn possess other species of forest trees new to this country; and much as I admire the class of plants now so popular, it is certainly a pity that it should usurp the whole attention of planters.

I am old enough to remember when the term “Arboretum” came prominently before us, and it was strongly urged on gentlemen possessing the means, or where in public gardens the situations were suitable, that planting all the newly-introduced trees that foreign parts afforded should be commenced forthwith. Now, public attention seems to be confined to the consideration of the Pinus tribe alone, and the additions made in other respects to the arboretum during the last twenty years or more have been very unimportant. Assuredly the case ought to have been different.

Do the hilly regions of the western coasts of the American Continent, both north and south, possess no other than coniferous trees? The vegetation of the accessible portions of China, Japan, and Northern India is certainly not confined to the evergreen species we have had from thence.

I am far from finding fault with the introductions that have reached us, but what I would like to see is more variety, and a wider departure from the confined fashionable path of the present day. Could not a move be made so as to lead to a fresh influx of such fine ornamental trees as some of our Evergreen Oaks, and our Magnolias, both evergreen and deciduous? Perhaps some other Acacia might be found hardy. In fact, once draw public attention in that direction and beautiful objects will be forthcoming.—H. L. T.

STEPHANOTIS FLORIBUNDA FRUITING.

IT would be interesting to know what culture is most conducive to the fruiting of the above most fragrant stove climber. The plant referred to by your correspondent, Mr. Morris, of which he had charge when foreman here, failed to fruit this season, although a much larger plant and in more robust health.

When living as gardener at Winch House, in Cheshire, the roofs of two Orchid-houses were entirely covered with a plant of this species, and, of course, it was subject to a great

amount of heat all the season through; but during the seven years I had charge of it I never once saw a single fruit. This plant produced annually bushels of bloom, and was, indeed, a most glorious sight when in flower. At more than one place in the neighbourhood the *Stephanotis* has fruited, but under what circumstances I cannot say. Does it fruit better in a pot than planted out? Or has heat or impregnation anything to do with the result? Perhaps some of your correspondents can enlighten us.—JOHN EDLINGTON, *Crom Castle*.

CHRYSANthemUMS AT MR. SALTER'S NURSERY.

MR. SALTER'S name is inseparably associated with the *Chrysanthemum*. Not only is he a most successful cultivator of that flower, but also the raiser and introducer of many of the finest varieties which we at present possess. Nor has he ceased to advance in that path of improvement in which his name has become celebrated, as his collection, which comprises every variety of known worth and many beautiful novelties besides, will amply prove.

In the open ground, two borders, each more than 120 yards in length, are filled with fine blooming specimens with flowers of every shade of colour, affording an opportunity of judging of the merits of different kinds for border purposes and of their comparative hardiness. For the latter purpose the late frosts, preceded by heavy rains, have unfortunately afforded too good a test.

But it is in the winter garden, a T-shaped house, 95 feet long by 18 wide, that the gems of the collection are to be found. On entering this the eye wanders over a mass of the large-flowering kinds, fronted by pretty *Pompones*, and beautifully arranged for effect; whilst on the other side of the winding walk which runs up the centre of the house are pretty groups of less height, and small circular beds of *Pompones*. To give relief from so much colour, Orange trees in fruit, *Araucarias* and other plants remarkable for the beauty of their foliage, and here and there plumes of the *Pampas Grass*, are introduced; and Ferns, such as *Adiantums* and *Scolopendriums*, are liberally used as edgings. One small clump near the entrance of the house contained variegated Ivy of the sort called *latifolia maculata*, the leaves of which are beautifully diversified with white, and contrasted well with those of a very dark kind, covering the ground at the base.

Among the new varieties already sent out were—Her Majesty, not very large but beautiful in colour, which is a silvery blush; Lord Palmerston, a rosy amaranth, peculiarly tipped with white; Dido, white; Abbé Passaglia, brassy amber; Antonelli, a fine salmon orange; Beverley, a remarkably fine large cream white; and Queen Margaret, a large rose Anemone, with a blush centre. Of varieties less recent were fine examples of Lady Harding, Progne, Versailles Defiance, Prince Albert, Mulberry (a fine colour though rather small), Triomphe du Nord, White Queen of England, Lady Margaret (large white Anemone), and host of others.

Of seedlings, Mr. Salter has several of the highest merit, and many more of great promise. Conspicuous among these are Prince Alfred, a beautifully incurved rose amaranth, which even in its present state is 5 inches across, and when grown for size will, doubtless, attain yet greater dimensions. Princess of Wales is another magnificent flower, an ivory blush, and it will probably grow as large as Prince Alfred. Both of the above will, doubtless, take a very high position when sent out. General Bainbridge is a beautiful bright cinnamon; Jupiter, a deep chestnut tipped with gold; Lord Clyde, a blood crimson, fine in colour, though rather flat. Mrs. Haliburton is another finely incurved, full-sized flower of a rose pink; Venus, delicate peach, with a high centre, is also large and finely incurved. Pelagia, yellowish-ivory; Bernard Palissy, orange scarlet; Hypatia, marbled rose; Florence Mary, bright red; Lord Brougham, dark chestnut; St. Patrick, deep rose and blush; and St. Margaret, large orange Anemone, are all sorts of great promise, and to these might be added several others which have not yet been named.

In a small house adjoining that in which the principal display is, are some very dwarf specimens, not exceeding

18 inches in height from the base of the pot, the plants being in some instances not more than half that height above the rim. They were formed by allowing the shoots to take their natural growth, and then bending them round the pots, which, in some cases, are completely hidden. Among them were beautiful specimens of Prince Albert, Her Majesty, Julie Lagravère, Julia Grisi, Progne, and some of the seedlings above referred to. In the same house were a pretty orange-and-yellow-mottled *Pompon*, another rosy lilac, both, however, being as yet unnamed; also, a variegated *Gazania splendens*, the leaves having a golden margin, and which is likely to prove a good edging plant.

Mr. Salter has, besides a large collection of hardy variegated plants, a very pretty variety of the *Pampas Grass*, with the leaves broadly edged with pure white; but the plant is not yet for public inspection, and being very young it would be premature to say much about it, but if it maintain the purity of its white when of older growth it will be a decided acquisition.

AMMONIA FOR GRASS LAND.

I WANT to apply ammonia to some grass land. I find sulphate of ammonia advertised at £17 per ton. I can procure soot (25 lbs. to the bushel) at £2 4s. per ton. Soot is said to contain two-fifths of its weight of salts of ammonia. If this be so, I can procure two-fifths of a ton of salts of ammonia—i. e., 8 cwt. for 4s., whereas 8 cwt. of sulphate of ammonia would cost 13s. Without valuing the other ingredients of the soot, is it not better to apply soot than sulphate of ammonia? or does the latter possess any special advantage over the salts in the soot?—R. I. I.

[Independently of the economy, we should prefer applying the soot. It will afford quite as much ammonia as the grass needs, and its other ingredients are beneficial to grass. We should apply it early in the spring and during showery weather.]

FLOWERS IN A WORKHOUSE.

WHEN recently inspecting, court by court and room by room, the large new workhouse in my neighbourhood, as a member of its visiting committee, besides being struck with the beauty and admirable arrangements of this building, the perfect ventilation, the separation of the hospital far away from the body of the edifice, the excellent cooking apparatus, the water supply, the chapel, and the all-prevailing cleanliness, there was one thing which very much surprised and pleased me in addition to everything else, it was this—the presence of Flowers in the Workhouse.

Now, some years ago it happened that, during the illness of the chaplain, I officiated as clergyman in a union poor-house in another county. But I own I found it to be very weary heart-saddening work, and I would not have been its permanent chaplain on any account. I felt that it was so different to meeting the poor in their own cottages, however humble they may be; there were the bare walls, the prison-like aspect, the absence of any decoration, even the simplest, nothing to break the cold look of the large windows and the blank stretch of the walls. Entering each room without the tap which true courtesy gives at cottage door of the poorest, brought a consciousness of my having before me, some of my own countrymen it is true, but they degraded in the social scale below the cottager, and this for very usually no sin, and all this oppressed me. Now, in visiting this present workhouse I experienced far less of this painful feeling, and this set me thinking why it was so—what was the reason? I soon discovered that it was partly owing to the presence of flowers inside as well as outside the building. The worthy master is both a lover of flowers, and, what always accompanies it, a man of taste. Thus, under the walls of the little square courts, miniature quadrangles, he has managed little borders, not more perhaps than 2 feet wide, but gay with common flowers, and with some flowering plants trained to the walls. In the centre of some of the larger courts my eye was greeted with that very effective flower-basket, if not too large, a portion of a trunk of a tree, rich with knots and fantastic in shape. In these were Scarlet Geraniums and other suitable plants. At the sunny end of the long wide passage

which runs the whole length of the house on the second floor, I found almost a greenhouse, with here and there in suitable places a flower-stand. In the large room occupied during the day by the old women, the long south window was actually full of flower-pots, and boxes with cuttings. Here was the cottage window most pleasantly brought to mind.

I noticed some disturbance of the gravel in the centre of the old women's court (and to the old of both sexes the warmest side of the building is most properly given). I asked the reason of the earth being thus disturbed, and received for answer, "Oh! master's going to make us a flower garden." So, therefore, during the long summer days the poor old bodies could sit on the benches in the sun, and blink and dose and enjoy their flower garden. Here, then, was a source of great pleasure to the poor worn-out working people (for it was the same also in the old men's court), here was something of a home feeling brought back to them. I would fain hope, by the presence of flowers. This it was too, which took away from my mind, to a great degree, that oppressive jail-feeling which I have described above. I should also add that this workhouse is built upon a piece of ground quite in the country and commanding a fine view. Now, all honour, say I, to the kind and tasteful master of the workhouse for his pains and care in making his poor inmates happier, as I really believe they are made happier, by the presence of flowers; for, remember, it was not only in his own apartments, but in all other parts of the house that flowers abounded. I would also say, that while Guardians duly and most properly provide the in-door paupers with the Book of Revelation as a main source of comfort, yet the book of nature is well calculated to soften and comfort sad, and, humanly speaking, hopeless hearts.

I send this little account to THE JOURNAL OF HORTICULTURE, that, as thank God, in this world, bad though it be, good is contagious as well as evil, some other master of some other workhouse, himself a lover of flowers, may make his house as attractive as the one of which I have spoken.

Let me in conclusion remark, that the excellent chaplain and visiting ladies of my workhouse have not only taken care that in the different wards "admonitory and consolatory texts should inscribe their walls," but they have given for decoration many of the gay pictures from the "Illustrated London News," "British Workman," and other periodicals, and even in the school-room there were pictures as well as maps: so that what with flowers in the courts, passages, and windows, and pictures on the walls, the cold cheerless criminal-look was quite gone. I felt, and fondly hope that some of the better class among the inmates felt too, that this workhouse was not only a dwelling, but almost a home.

—WILTSHIRE RECTOR.

CHRYSANTHEMUMS IN THE TEMPLE GARDENS.

HEAVY rains succeeded by sharp frosts are not conducive to out-door displays of Chrysanthemums, and, hardy as that flower is, it could not fail to suffer under such circumstances; still the general effect of the beds in the Temple Gardens is very good, though some have been touched with the frost.

In the Inner Temple Mr. Broome's principal border, about 70 yards in length, is as usual covered with canvass, except in one part where glass sashes have been used. This is a great improvement, for in November days in London there is no light to spare, and the transmission of what little light there is is soon in a great measure prevented by the canvass being covered by "blacks." It would be desirable if the whole of the back of this main border were temporarily covered with glass; the cost would not be great, and in the long run glass would, probably, be more economical than canvass.

In this main border an extensive collection of the large-flowering varieties is ranged, diminishing in height towards the front row, which consists of Pompones.

Among Whites—Vesta; Snowball; Beverley, a new and fine cream white; and White Formosum, seem the best.

Of Yellows, the most worthy of remark are Etoile Polaire; Astrolabe, a bright early kind; Chevalier Domage, very useful for borders; Plutus; Golden Queen; Yellow Perfection;

Formosum; Golden Hermine; Cherub, a fine golden amber; and Jardin des Plantes, one of the finest of its colour, golden yellow.

In Orange and Buff we find General Slade; Cassy, very fine; Orlando; Mr. Jay, a new reddish-orange; Dupont de l'Eure; Antonelli, salmon orange; and Lord Ranelagh.

In Reds—Riflemen, Madame Poggi, Prince Albert (crimson), Dr. Rozas, Progne, and P'io Nono are the best.

In Lilac and Blush, &c., we have Queen of England, almost white; Alfred Salter, very large, delicate pink; Ariadne; Hermine; and Aimée Ferrière, white tipped with rosy pink, and very beautiful.

Of Pompones, the most striking are—Salamon, rosy carmine; Mr. Astie, yellow Anemone-flowered; Duruflet; Cedo Nulli; Lilac and Golden Cedo Nulli, the former a sport of Mr. Broome's own which answers admirably for bedding; Aurore Boréale; Argentine, silvery white; Hélène; Berrol, a very early golden yellow; Mustapha; St. Thais; Bob; and President Decaisne.

Besides the main border referred to above, there are two others equally well filled, stretching north and south, one 70, the other about 96 yards in length; and there are in addition some two dozen small circular beds filled with Pompones neatly trained by means of a stake in the centre, which is highest, whilst the surrounding plants are tied down. This is the fourth crop which these beds have borne, the first being bulbs, the second early annuals, the third bedding plants of various kinds, and the present one Chrysanthemums put out in the end of September. Thus a succession of bloom has been secured throughout the season, and if gardeners took a lesson from the example which Mr. Broome has given, our flower gardens would not be gay for merely some three or four months out of the year, but from the time that the early bulbs peep above the snow till winter comes again.

In the Middle Temple Mr. Dale has also a good display, including remarkably fine blooms of Queen of England, Lord Palmerston, Campestroli, Cherub, Little Harry, Novelty, Favourite (a pleasing rosy pink), Oliver Cromwell (a new ruby of fine form and very smooth outline), Golden Hermine, Plutus, and Yellow Perfection. There are several fine blooms of Fleur de Marie, a large white Anemone. Vesta appears to be one of the best of the Whites for lasting. Golden Christine is very free in borders. The beds on the grass are filled with masses of Pompones in full bloom; the two circles near the river are each composed of ten varieties radiating from the centre, and present a gay appearance.

GOLDEN-VARIEGATED ARABIS AND CENTAUREAS.

MR. ROBSON will be pleased to hear that the variegated Golden Arabis lucida exists in all the golden beauty that has been said of it. It is a very dwarf compact-growing plant with lanceolate leaves about 4 inches long, with a broad margin of gold of the same hue as Geranium Golden Chain. It is an entirely distinct species from A. albida, having had its origin from A. lucida, from which it is a sport, and occasionally it goes back to the original. A. albida variegata is grown here also, and is considered a very pretty and useful plant with a cream-coloured variegation, but it is altogether a coarser plant than A. lucida variegata, which latter I consider a perfect gem for edgings, and more especially for long straight lines—so much so that it is considered no longer necessary to grow such great quantities of Golden Chain. A. albida is a most useful spring-flowering plant on account of the enormous quantity of pure white blooms which it yields at that season.

Centaurea argentea, as far as my experience goes, is not nearly so fine a plant as C. ragusina, and the same may be said of C. gymnocarpa. They are graceful plants, but not more so than C. ragusina, and are not nearly so white.

I consider C. ragusina and C. candidissima to be the same. We have at present specimens of this variety that were planted out in May, and that are now nearly a yard across, and it would be difficult to imagine more beautiful objects, raised as they are on knolls formed by blue bullets from the sea-beach. It is really a wonder this fine old plant has not been more popular long ago. I take some pride in

it, as I believe I have the credit of making it popular in Scotland, where it is now grown in quantities that surprise the southerners when they cross the border.—D. THOMSON.

SOME GARDENS WORTH SEEING.

CORNWALL.

Name.	Proprietor.	Gardener.	Station.
Cardlew	Sir C. Lennox, Bart.	Mr. Johns	Truro.
Trebartha Hall	T. Reid, Esq.	Mr. Dawe	Liskeard.

DEVONSHIRE.

Werrington Park	Duke of Northumberland.	Mr. Snowden	Tavistock.
Mount Tavy	J. Carpenter, Esq.	Mr. Agar	Tavistock.
Sydenham House	J. Tremayne, Esq.	Mr. Durdan	Tavistock.
Kelly Hall	A. Kelly, Esq.	Mr. Bloomfield	Tavistock.
Lifton Park	H. Bradshaw, Esq.	Mr. Mounsead	Tavistock.

There is a railway being made from Tavistock to Launceston, so that some of the gardens will have stations nearer than Tavistock.—K. J. B.

TRENTHAM.

(Continued from page 395.)

WE have already indicated the chief mode of communication for pedestrians, by the iron bridge over the river, between the kitchen garden and the terraced gardens and mansion. From this cottage garden, so concealed by shrubs and trees, there is by means of a boat and rope a nearer access to the offices and the rooms, &c., on the east side of the house. From that ferry across the river lined with beautiful aquatics, you observe a little to the northward the arches of an ancient bridge, over which the road that passes the carriage entrance to the kitchen and forcing gardens we have already alluded to is continued past the commodious Trentham Hotel, which must be a boon to the many visitors, and through more of the village, until, entering the park on the left, you shortly arrive at the beautiful entrance gates, with a chaste Italian lodge on each side of them, and only a short distance from the mansion, which is in the same style of architecture, only richly adorned with lofty balustrading, urns, vases, &c. The architectural beauty of the mansion, however, we must leave to others to describe. The entrance is on the west side, and is thus singular, that instead of being ushered into a hall or lobby, you at once pass into a lofty conservatory chiefly ornamented with creepers and Ferns, and having broad stone pathways, that to the north leading to the public rooms, and that to the south to the more private apartments of the family. In connection with this is a court with flower-beds, and beautiful stone plinth edgings, the Geraniums having a brighter hue than ever they have out of doors, unless in a continuance of dry, sunny weather. The nearest approach to these Scarlet Geraniums in brilliancy were grown out of doors in large boxes by the side of the conservatory, and, from receiving less rain, and much less feeding room for the roots, they far excelled those that had been exposed to the drenchings of that watery place. Not but that the beds

out of doors were beautiful, but the bright blaze of these protected Geraniums confirmed what we lately advanced—that a glass-covered flower garden, with plenty of air, and moisture as needed, would give a greater brilliancy to most of our bedding plants; and even an acre, or half an acre so laid out, would yield more satisfaction than dozens of acres in the usual bed style out of doors. And then just think of the nightmare visions, the proprietor, if at all enthusiastic, and the sleepless nights of the gardener, if at all anxious, that might be prevented, but which must now be endured, when several select parties are coming to see “your beautiful place,” and the barometer tells you as well as the aches in your own body, if the rheums have got hold of you, that you will either have a hurricane of wind, or a drenching, desolating rain.

From this inner-court flower garden you enter the private conservatory, which forms the west wing of the mansion, on the south front. This, especially when the family is at home, is always kept a picture of floral loveliness. The engraving from a photograph will only give a slight idea of the beauty of the massing and foliage and creepers. It gives no idea of the artistic effect produced by marble statuary, vases, &c., for if not moved these alone would have occupied the foreground, and broken and concealed the foliage. This view, as well as that of Mr. Henderson's residence, and the temple to follow, were taken by a self-taught artist or amateur, Mr. Kirkby, of Trentham, and if the engraving is as good as the photograph, there will be little to find fault with. The conservatory is 50 feet by 35 feet.

Between this conservatory and a protruding wing on the east side is placed the slate terrace. The east wing, the same size as the conservatory, on the principles of balancing and uniformity, ought also to have been in the conservatory style; but this somewhat plain end that flanks the slate terrace, is relieved by the consideration that beyond the windows facing the south is the principal dining-room, for however much we love the beautiful, we must pay our regards to the more material and substantial. We fear that these dining-rooms often make sad wrecks of our ideas of the ethereal as respects persons and things, and bring us, however unwillingly, into the regions of stern reality. This somewhat tame end is also relieved by fine statuary, most of the statuary being of a colour as black as ebony. Similar statues are also placed at the west end next the conservatory, and also in places along this terrace; and each of these is in such a distinct and artistic attitude as they front each other, as to lead us to conclude that they must represent some athletic contest or game of skill, but what, our limited acquaintance with general or mythological lore prevented us from knowing.

Before proceeding farther, we must here allude to some little matters that gave us great pleasure, and also because showing the refined taste that is brought to bear on the simplest details. The mansion itself is painted or coloured of a deep creamy stone colour. Close to the base are semi-circles cut out of the slate terrace, and these were filled with blue masses of *Lobelia speciosa*, and we can conceive of no colour more striking in the position close to the walls. Then the whole of the sills of the lower windows of this centre front were filled each with a China-box just to fit it. Plants are grown in other boxes just made to slip in, so that the China-boxes look as full and overflowing as if the plants had never been anywhere else. These China-boxes are kept filled all the year round with plants suitable to the season. When we saw them each box was a dense mass of Golden Chain Geranium. What, and so close to such a coloured wall? Yes, it is true, and most beautiful they looked. But that you may take our word for it, we must also tell you that the pretty Wedgwood ware was chiefly white and green; but the upright bars and a rim at the top were of the richest blue, and the glass of the windows behind the boxes was of a light mauve colour. We thought at first that the blinds were so coloured, but found out it was the glass. Under such circumstances the Golden Chain was peculiarly at home.

The sombre colour of the slate-paved terrace contrasts also well with the colour of the mansion. From the conservatory to end wall of dining-room, it is 141 feet in length, and is 49 or 50 feet in breadth. There is an open space in the centre opposite the noble fountain in the flower garden.

On each side of this centre is a large oblong bed, and a smaller one on each side of it. The large bed is 27 feet in length, and 13½ feet in breadth, but the ends instead of being square are protruded and rounded artistically. The sides of these beds are of fine moulded stone 13 inches in height. The large beds were thus filled—two dense rows of

purple *Verbena* next the stone moulding; then two fine rows of *Flower of the Day Geranium*, grown only for the foliage, all the flowers being removed; and the centre was filled with *Trentham Scarlet Geranium*, except what was taken up with a sarcophagus-formed vessel, and that was filled with *Agapanthus umbellatus*. The *Trentham Scarlet* does

better than any other scarlet here, though seemingly of the Tom Thumb breed. The smaller beds stood across the larger ones, and were we to describe them the same way, it would be by saying that they also were 13½ feet in width, and 6½ feet in length. These were each centered with a statue, and filled with pink *Geraniums*, with a broad border of *Lobelia speciosa*.

We have several times expressed perhaps only our prejudices against concealing the base of statuary even by flowers; but the same objection would not apply to these sarcophagi. There is something not only instructive but pleasing and poetical, in associating the ideas of our last sleep with beautiful flowers. Few would be inclined to go so far back as to recollect that the name conjured up ideas

of a caustic limestone, that ate up in a very short time all dead animal matter committed to its care. Even then we might moralise on the wonders of this world of change and progress, where life *now* must be sustained by life that *was*. The fine rich umbels of the Agapanthus seem to tell us that

even beauty must be sustained by a due portion of decomposition. Be that as it may, we must state that these heds in their beauty evinced the most careful and skilful management.

R. FISH.

(To be continued.)

THE LATE MR. DONALD BEATON.

MANY of our subscribers not having our first series, we are induced to republish the very excellent portrait of our deceased friend, which is in the thirteenth volume of that series, and we accompany it with a very interesting relique,

the last contribution he had the power of writing for this Journal. It was written in answer to a note we forwarded to him. Paralysis seized him before he had returned it to us, and it has just been found among his papers.

CHANGING THE COLOUR OF THE PEA BY CROSSING.

"I NEVER cross-bred a plant intentionally in my life, so I am not about mounting a pillar like Simon Stylites, and proclaiming myself an authority, but I have been a cross-breeder of poultry, and have observed facts there which make me hesitate from agreeing that it is "absurd" to think that the skins of Peas may be altered in colour by the pollen which fertilised them. For instance: Cochín-China hens lay buff-coloured eggs, but if they are associated with a Dorking or Spanish cock the shells of their eggs frequently, after a time, are laid nearly white. Again, another fact we all have observed, a white woman has white children, but if

her husband is a black man her offspring becomes dark-skinned.—*February 3rd, 1863.*"

[The above is a most interesting fact, bearing directly on the question of changing the colour of the garden Pea by the influence of the pollen; and the two cases, as far as I know, stand isolated, the one in the vegetable and the other in the animal kingdom. The other fact adduced goes directly against the inference he draws from it, for to bring it within the analogy it is not the offspring of the white woman that would or should be the dark-skinned, but the white woman's own skin. It is not the offspring of the crossed Pea or second generation which the believers in Gärtner's cross ac-

knowledge, but the Pea itself. The Pea was crossed, and the cross changed that Pea, not the offspring of the Pea, although we may infer the offspring to be of the same colour as the parent. By that analogy it would be necessary to adopt the notion that the male influence in the animal kingdom changed the colour of the skin or coat of the female, not the skin or coat of their offspring, or second generation. Now, if we analyse the more plausible side of the question which is thus raised—the egg changed by the influence of the male, we shall be able, without any stretch of idea, to dispose of it as easily as of the other. The egg in the feathered race represents by analogy the pea-pod, not the body of the Pea; and to have a bearing on the question in hand, Gärtner's experiment would need to change the colour of the pod, not of the Pea. But the fact is, we can trace no direct analogy between the modes of fecundation in the two kingdoms; all we know is, the effect of the mode is the direct opposite in the two. Repeated approaches of consanguinity is a well-known cause of degeneracy in the animal kingdom, and the surest way of improving races in the vegetable kingdom—that is, improving flowers and fruits; and yet when we push the inquiry or the mode of improving to its ultimate, we find, or, at least, we have already found, that these improvements have been acquired at the expense of the health of that strain or race ere we reached the limits of the ultimatum or final stage of improvement, as florists could tell us from their records of their different "worts," every one of which has been getting less and more less healthy, and by consequence more difficult to preserve, from the first cross by in-and-in breeding.

This seems the best place for me to make a suitable apology to Mr. Darwin, and to ask a thousand pardons for my seeming contradiction; but I had not the slightest idea even of contradicting him, much less of discourtesy. I wrote hurriedly and very earnestly for a particular reason—well knowing that every word Mr. Darwin says carries great influence with it to the ends of the earth. I knew Gärtner was the least reliable of all the old authors; that he published the greatest absurdities about it, above all who wrote before him; that his first edition was the text-book of all who wrote upon crossing without experience in it themselves; and that it would be a thousand pities if Mr. Darwin lent the power of his authority to Gärtner's speculations, which have not advanced the art one single degree. It cannot possibly be an attack on an author for another to expose errors he might have fallen into. I have no idea, or any wish, but to speak the truth only about this author, when I affirm that nine-tenths of his nine thousand recorded experiments are nothing better than idle speculations. I am satisfied there are not nine of them out of nine hundred which would come exactly alike next year or next trial the same season, and such might be recorded a thousand-fold without helping the art of crossing to advance one single step. As the work of an amiable naturalist, and as pleasant reading, I have no doubt but Gärtner will be read as long as Sir Walter Scott. I only wish I could read him in the original, or that he had a good practical English reviewer instead of a highly scientific one.—D. BEATON.]

HEATING A GREENHOUSE FROM A DINING-ROOM FIRE.

IN reply to "A DEVONSHIRE VICAR," in your Journal of the 10th inst., page 372, I beg to suggest the following:—

Some thirty years ago I recollect being in a room that was heated by means of the surplus hot air from the kitchen grate. It was, I believe, thus:—An iron tube about 1½ inch in diameter commenced its course at the lower end, and on one side of the kitchen fireplace; it passed thence to the back of the fire, where it doubled upon itself, up and down, each fold touching the former one to the full width of the grate, the whole forming the back of the grate. It was then carried through the partition-wall and made its exit by the side of the dining-room fireplace, the outlet of which was guarded by a slide, as also was the inlet on the kitchen side. Thus when the slides were open and a fire was in the kitchen grate, there was always a plentiful supply of hot air in the dining-room, which could be regulated by the slide in the dining-room.—J. B.

WORK FOR THE WEEK.

KITCHEN GARDEN.

EVERY opportunity of favourable weather should be promptly employed in carrying out whatever digging, trenching, and draining have been marked out for completion during the winter months; if deferred until a later period severe weather may set in, and thus the operations may be retarded to the manifest loss of many advantages. *Brussels Sprouts*, when the head is cut the dead leaves should be removed, but none of the green ones, as they protect the young side shoots. The same may be said of Scotch Kale and other winter greens. *Cabbage*, take advantage of a favourable day to earth-up the autumn plantations. It not only invigorates but prevents them from being loosened by the winds. *Cauliflowers*, never neglect giving air daily to those under hand-glasses and in frames, unless during severe frost. If the plants are now elongated by an insufficiency of air they will be very liable to button-off. *Endive*, any that have been planted in frames should have air freely admitted to them to prevent rotting. *Mushrooms*, the beds out of doors should have a thick covering of straw, over which should be placed mats to protect them from wet and frost. When the straw is wet it should be replaced with dry. *Radishes*, on a dry warm border a few beds of Early Frame or Short-topped should be sown either alone or with the Short Horn Carrot. Cover the beds with straw or litter till the seeds germinate, when they should be uncovered every day when not frosty. A frame should likewise be placed on a gentle bottom heat for a sowing of the above to draw early. *Strawberries*, we do not approve of the practice of cutting off the leaves indiscriminately at the winter dressing, conceiving them to be designed by Nature for the protection of the buds which are to produce the future blossoms. On the score of neatness, the removal of such as are decayed will be sufficient, and to this, if done carefully, there can be no objection. Dig in these trimmings now with a portion of old hotbed manure between the rows, digging down only in the centre so as not to disturb the roots too much. The slight root-pruning caused by this process will be rather beneficial than otherwise, and the dressing will be placed just where the new fibres produced in spring will be able to profit by it.

FLOWER GARDEN.

If not already done, get all borders neatly trimmed-up for the winter. Valuable plants, as variegated Hollies, Rhododendrons, &c., if not growing as freely as it is desirable that they should do, would be benefited by a liberal allowance of rotten manure or well-decayed leaf soil applied as a top-dressing, covering it with a little fine soil, and working it into the ground towards the extremities of the roots. But Rhododendrons and what are generally termed American plants bear removal so well, that these, where not growing satisfactorily should be taken up, the ground well prepared by a liberal addition of peat or leaf mould, and replanted. While the winter continues mild the planting of deciduous trees may be proceeded with, providing the state of the land will permit of the operation being profitably performed. Deciduous shrubs may be pruned whenever there is time, except during severe frost. Many of the larger-growing plants will only require going over once in two or three years. Smaller-growing shrubs, as some kinds of Cytisus, Spiræas, Deutzias, &c., should, however, be pruned annually if a good show of flowers and uniformly-shaped bushes are desired. Secure shrubs and young trees from the effects of boisterous winds by stakes. Plant climbers, as Ivies, Clematises, &c., and train and support creepers against walls generally. Where walks are in good condition but have weeds still making their appearance on the surface, recourse should be had to hard-picking, and the use of the rake and hoe should be avoided at this season as much as possible. These instruments do more harm than good by breaking-up the surface, while the destruction of the weeds is not secured.

FRUIT GARDEN.

When orchard trees have been for some years left unpruned some of the branches will require thinning out; keep the middle of the trees open to admit air and to promote the formation of fruit-buds on the interior branches. Pears should not be allowed to become over-ripe before being

used; also look over the whole stock as often as time can be spared. Any of the choice varieties that do not ripen properly in the fruit-room should be removed to a warm dry room for a few days, which will be found to improve them greatly.

FORCING-PIT.

Particular care should now be exercised as to the application of water, atmospheric humidity, air, and heat, the latter should be generally applied a little extra by day with air, and very sparingly at night for some time to come. Gentle fumigations with tobacco should be occasionally given, and a little sulphur applied, in a liquid state to the heating apparatus when moderately cold, but by no means when hot.

GREENHOUSE AND CONSERVATORY.

The supposed necessity of resorting to fires in greenhouses may often be obviated with great advantage to plants by the use of night coverings. Double mats, or whatever may be devised for the purpose, will, except in extreme cases, maintain a night temperature of from 35° to 40°, which is an amount of night heat sufficient for the ordinary occupants of mixed greenhouses during the winter months. Stop the leader of every shoot of the large plants of *Pelargoniums* which are wanted to be in bloom in June, and also of the young plants struck the past summer, to cause them to push side shoots. *Tropaeolum tricolorum* and the other tuberous roots must now be potted if to bloom next season. Encourage *Tropaeolum Lobbianum*, it will bloom through the winter; also *Salvia splendens*, *fulgens*, *gesneræflora*, they are fine for autumn and winter bloom.

PITS AND FRAMES.

As a change from the present to severe weather may come on suddenly, be provided with ample means for covering these structures should it occur. *Mignonette* and *Neapolitan Violets* will require abundance of light and air to keep them from damping. Pot *Ixias*, and place them in a cool frame, or plant out of doors in a warm place. *Cinerarias* may be kept for some time longer in a frame, but must be protected from frost.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

THE fine dry days were chiefly used in clearing away the old stalks of Cauliflowers, old *Pea-haulm*, and *Pea-stakes*, as we could not get on the ground before on account of the wetness. Took up a piece of *Sea-kale* and *Rhubarb*, and placed in the Mushroom-house in pretty-well-spent manure that would give a bottom heat of about 75°, the atmosphere of the house being about 55°; but most likely we will raise it to some 5° more for a few days, as we shall want an extra supply of Mushrooms next week. If the *Sea-kale*, &c., do not come as soon as we wish, we will cover it over with straw, or place some hoops over it and a mat covered with hay, so that the air in the enclosed place shall be warmer than the general air of the Mushroom-house; for though that may be raised in temperature now and then for definite purposes, we always imagine that if the temperature is long above from 55° to 60°, the present gain will become a future loss, as the beds will sooner be exhausted. In removing our heap of Mushroom-spawn to a dry shed there were a few bricks not sufficiently spawned, and to avoid the covering-up from rains, &c., out of doors, we placed them in the Mushroom-house, and covered over with a little hay, having no doubt but that in a fortnight they, too, will be fit for placing in their dry quarters. Nothing tends to make the spawn exhaust itself more than being allowed to remain long in a damp place. Good spawn is best known by its pleasant Mushroom-like smell, and by the whole of the pieces being permeated by a whitish substance in hair-like fashion as to size, for if the filaments are as large as sewing-thread, these individually are too far gone for running in a bed. Even such may produce Mushrooms in a favourable position, but they seem to have lost the power of generating and filling the mass of a bed with productive spawn. Gardeners have rendered the culture of the Mushroom by means of its spawn a matter pretty well as certain as the obtaining a good Cauliflower. Who, by means of spawn or plants, will help them to attain the same proficiency in the culture of the Truffle and the Morel, which, for all the higher branches

of cookery, are as much used as the Mushroom? One advantage they would have over the Mushroom is that when obtained at the right time they keep good for a long period. Had we more time we certainly should like to try their cultivation in different ways. "It cannot be done, sir," should seldom be resorted to unless in a demonstrated impossibility. Owing to the fugacious character of the Mushroom it often happens that you may have a bushel of them when they are of little use, when there is nobody of consequence to eat them; and then when a large party suddenly comes, there may be none or only a few to get, though they might have been had by the extra fillip spoken of above if the gardener had only known. We expect that ladies and gentlemen would find that much of the solid-resistance-points which they present to their staying friends would give but imperfect satisfaction, unless the artiste of the kitchen knew some time beforehand, so as to have the meat, the poultry, and the game in the best possible order. When it is not considered worth while to let the gardener know anything of these great events beforehand, it is just a matter of chance if the products of the garden come in when most needed. A little more of a clear understanding in such matters would be to the benefit of all concerned.

The heap of chopped *Hollyhocks*, chopped *Asparagus*, and flower-stalks, mixed with leaves and dung, has come in most useful for slight hotbeds, and for placing a covering over the border of an early vinery, the surface of which had been covered with a thin coat of tar and sawdust. The mild hotbeds will do for placing some fresh hotbed bedding plants in, and just setting in movement the roots of some Vines in pots.

We have been so taken up with cleaning, that with the exception of stirring the ground amongst young Cabbages, Cauliflowers, &c., and giving a little more dry earth to *Celery*, with a little ashes or burnt earth and rubbish next the stems, we have done but little in moving the ground, though there could be no better weather for doing so. In many gardens, however, what ought to be done must wait until there is time. We always prefer moving ground, if possible, in fine, bright weather. Trenching and ridging cannot be better done than now. In light ground, trenching with a rough surface we consider to be better than ridging. Ridging is always best in stiffish soils, whether the ground be turned up one, two, or three spits deep. Those who have large places, and like us begin to be a little deficient in memory, should keep a digging and trenching book. In trenching, every second or third year it is advisable to break the subsoil, and bring a little of it to the surface. A great deal would do mischief; a little will always do good, and, exposed during the winter, it will mix well with the older soil in spring. This plan is especially suitable for all long-rooted plants, as Carrots, Parsnips, Beets, Salsafy, &c. In old gardens the soil is apt to become too rich for them, which encourages them to spread into finger-and-thumb-like roots, instead of one fine large one, and as straight as an arrow. The digging down, rather trenching down, such ground three spits in depth, or two spits if the soil is shallow (in either case bringing up an inch or two of the subsoil to mix with the soil that was lowermost, but now placed on the top, in the ridge state), would, if the surface were moved once or twice during the winter, render the soil nice and friable before spring, and the richest soil being at the bottom, the roots would be inclined to go straight down towards it. Such old soil would also be greatly benefited by a thin surfacing of quicklime, or burnt clay; but the most surprising effects will often be produced on such old, rich ground by a dressing of peat earth, so far as Carrots are concerned, using a dressing of lime with the peat. If even for this crop alone the ground were so prepared, the deep stirring and bringing a little fresh undersoil to the surface would, in course of time, take all the garden in regular course.

It may here be worth mentioning, that in trenching and ridging now, the work should be done differently from the way it should be done in spring. At the latter period it would be necessary to break the different spits as they were turned over. At this season it is best to take rather thin slices on the spade, and turn them over in a rough state, so that the air and the frost of winter may freely penetrate. From the crumbling-down it will be solid enough before the

spring comes. It is next to useless to describe such a simple operation as trenching or ridging two or three spits deep. An opening should be taken out of the necessary depth, and 2 feet in width. The bottom of the trench should be loosened with a pick if necessary, then turn over the top spit of the next 2 feet into the bottom, follow with another or a double spit as deemed advisable, and make the surface roughly level, or, in all grounds at all stiff, lay the last spit carefully up in a ridge as steep as possible, as the sharper the angle at the top the more will the air and the frost penetrate, not only the ridge, but the furrows between down to the bottom of the trench. If a sharp frost should penetrate 2 or 3 inches, it is a capital plan to turn these ridges over, and thus the whole surface soil is frosted, and no better employment could be found for a keen frosty day. It must be done before the frost is so hard as to prevent a good sharp spade penetrating when there is a sturdy arm and a firm foot behind it.

Talking of frost, however, seems somewhat out of place in such fine pleasant weather as we now have, but a little of it in moderation will soon be very acceptable. The well of our old-fashioned ice-house, without the assistance of a bit of straw or any other covering has lasted us now two years, but has failed at last. A little mud has collected in the bottom, but as it has become dry that shows there is no stagnant water; and, therefore, instead of making the well any deeper we will merely place a few faggots in the bottom before filling again, when we have the chance. We might have had a little in November last year, but it was supposed it would disturb the game before a shooting party. For a similar reason our tree leaves will be pretty well gone before we can take them. Ice is, no doubt, a great luxury, especially in summer, and is most valuable as one of the chief crutches in some of the worst afflictions to which humanity is subject, but it becomes a troublesome and an expensive affair when it has to be brought from long distances. Is it impossible to bring more into common use those chemical freezing mixtures of which we read so much, and which we believe some of our greatest confectioners use largely? Perhaps this may catch the eye of some one able to give particular information, as often when new modes are discovered it may be years and ages before these are brought into everyday practice.

FRUIT GARDEN.

Very much the same as last week, only we put a little more litter, and we would have given more if we could over the border of the late viney, and put the old sashes and straw covers over that again, our object being to keep the leaves green as long as possible. At one end the leaves are becoming yellow, and there we have mostly cut the fruit. If we could have kept the roots a little warmer the ripening of the leaves might have been a little more delayed, and, consequently, the fruit would have hung longer in a fresh plump state. As soon as the leaves turn yellow they must be removed, and after they are removed more care must be taken on frosty nights, as the bunches are more easily frozen when there are no leaves to shelter them. We trust the bulk of our leaves will be greenish for some time in this late house. Of course, all laterals to speak of have been removed some time ago, except some little twigs which furnish a few small leaves for garnishing on particular occasions. We have already stated that we put about a foot of our mixed fermenting-heap on a Vine-border, to which we will apply heat a month hence inside. We want the roots to precede the tops a little. We would also have placed wooden covers on the top of the litter if we could have commanded such a convenience, but satisfied ourselves with a little long litter, as we could not do better.

ORNAMENTAL DEPARTMENT.

Much the same as last week. Never had so much labour in clearing the wrecks of the flower garden, the beds were so excessively thick and strong, notwithstanding the dry summer we had. However, there will be more for the fermenting-heap; but there has been so much that the men seem much more tired of it than they were of the planting time.

A stray remark about old hotbeds and frames for bedding plants has brought us several inquiries; and we will meet these inquiries, first by saying if you have a good frame, or a

number of them, have nothing to do with the old hotbed if you can help it, but set the frame on a piece of high, dry ground in preference. If this had been the month of July, this is the plan we would have recommended: Choose your position for the frames, raise the ground 6 inches above the level, for a space wider by 2 feet, and longer, too, than the frame, firm it well, let it slope from back to front 6 inches. After firming it well run it over with tar about the thickness of a new halfpenny, throw some gravel and sand over it, and it will be as hard as adamant before you want it in the end of autumn for your plants. Place your frames on them, and for a lasting job it would be best to surround them with a bank of earth or soil 15 inches wide at bottom, and 9 inches at top, beat it firm, make it smooth, paint it with tar, and for 2 feet beyond, and cover with sand, road drift, or fine gravel. This will throw all rain away from the frame, and no moisture will rise from the bottom inside. Recollect that moisture and damp are the worst evils in winter. You cannot do the ground inside with tar now, it would kill everything, but the outsides may be so done, if care is used in air-giving; the inside may be elevated with dry earth, chalk, &c., or it might be done with earth smoothed and coated over with pitch, which would soon dry, and emit no disagreeable effluvia, and in either case dry gravel or dry ashes rough would do inside. In such a case the watering should be so done as not to spill a drop; in fact, the pots should be taken out to be watered, and be then replaced when drained. In severe frost a little litter might be thrown over the earth banks, and, of course, the glass must be duly protected. In very damp weather a piece of lime might be put inside, or a bottle or two with warm water, which, with air on, would cause a more rapid circulation inside, and make the atmosphere drier. If earth is not used, the next best would be straw neatly tied against the wood, and the sashes long enough to throw the water past the straw.

The best covering for the glass of such pits would be wooden covers made to fit to each other; the next best would be asphalt fixed to frames; the next best tarred cloth or frigi domo fixed to poles, which two people can easily manage. Good waterproof covers 6 feet by 4 are also advertised. We have supposed the above frame to be about 6 feet in width.—R. F.

COVENT GARDEN MARKET.—Nov. 21.

The supply both of fruit and vegetables, in consequence of the mildness of the weather, continues to be ample, much more so than is usually the case at this season. Pines are in great abundance, and prices have a tendency to decline. Of Grapes the supply is quite sufficient for the demand. Melons from abroad, which are the only ones now in the market, are plentiful. Apples and Pears consist of the same sorts as mentioned in last week's report. The Potato market is still heavy. Of Asparagus a few bundles may now be had. Cut flowers principally consist of Roses, Violets, Chrysanthemums, Mignonette, Geraniums, and Chinese Primulas.

TRADE CATALOGUES RECEIVED.

William Bull, King's Road, Chelsea.—*List of New, Beautiful, and Rare Plants.*

B. Whitham, Reddish Road Nurseries, Stockport.—*Catalogue of Forest, Fruit, and Ornamental Trees.*

Chivas & Weaver, Chester.—*Priced List of Forest, Ornamental, and Fruit Trees, Evergreens, Roses, &c.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Dew (*H. P. B.*).—Dew does not rise from the earth. It is a deposition of atmospheric moisture. You will find an explanation of that and other phenomena interesting to gardeners in "The Science and Practice of Gardening," which you can have free by post from our office for 3s. 4d.

DISSOLVING BONES (*A Subscriber, Cheshire*).—The cheapest mode of buying sulphuric acid is by the carboy. It is very cheap, and any chemist could supply you. The following proportions and directions will be a sufficient guide:—On a small scale, 6 lbs. bone dust, 3 lbs. oil of vitriol, 1½ lb. water. Sprinkle the water on the bones first, and then add the vitriol. Be careful, for it is very corrosive. Use a cask large enough to hold twice the quantity. As much ashes or water may be mixed with the dissolved bones as will enable you to sprinkle it over the plot of ground regularly. The above quantity of bones and vitriol would be enough for 100 square yards.

SCREEN BEFORE A ROAD (*Hesperis*).—Laurels will do very well if you do not wish for a tall screen. Arbor Vitæ grows somewhat taller than Laurels. We would plant Laurels, Portugal and common, and Hollies if we wanted a low screen, and add Firs at the back if these were too low. From now until April, in mild weather, is the proper time to plant them. You are rightly informed, Laurels grow fast and soon attain a moderate height. To shelter the house the various Conifers are well adapted for the purpose; but, instead of planting Firs exclusively, we would plant but one or, at least, only two of a species. They would be rather more expensive, but that would be amply compensated for by the additional interest they would afford you. You would have many and varied forms, which, we think, would please you more than monotony. Firs, Pines, Cedars, Cupressus, Taxus, Araucaria, Cryptomeria, Picea, and Wellingtonia gigantea, can be had at any nursery for a small sum. The beginning of March is a good time to plant them, but we prefer moving them from September and October to the middle of November. The Laurels move best when about 2 feet high, and Firs at any size providing they have been duly transplanted. Three feet is a good size, but those which are less are cheaper and are replanted with greater safety.

BONE DUST FOR A VINE-BORDER (*A Constant Subscriber, Yorkshire*).—The bone dust should be applied in March, and the guano at the same time. The bone dust should be neatly worked into the border without going so deep as to injure the roots. The guano had better be spread on the surface at twice—in March and May. Rains would wash its fertilising properties down to the roots; but should you dig it in there is a probability of its reaching the roots in its pure state and destroying them. We think it would do them good, unless the roots are deep, when lifting would be better.

MISTLETOE ON A PEACH TREE (*Idem*).—We never heard of Mistletoe growing on the Peach, either in Yorkshire or in any other locality. It is usually found in Yorkshire on the Crab Apple, Thorn, Poplar, and Lime trees. We have not seen it on the Oak, Ash, Elm, nor any other common tree. We should be obliged by correspondents stating whether they have found it on any of the Conifers, as there is a prevalent opinion that it will not grow on trees affording resin. Though it grows freely on the common Thorn (*Crataegus oxyacantha*), we failed to make it grow on any of the North American species. We should also be obliged by any information relating to Mistletoe found on any description of tree other than those specified.

STEPHANOTIS FLORIBUNDA AND IPOMÆA HORSFALLII PRUNING (*An Old Subscriber*).—The Stephanotis may be pruned at once. The pruning is simply thinning-out the shoots and cutting out the weak, old, and useless parts. You might probably obtain a second bloom, but we would advise you to be content with one rich display, as too much excitement has a tendency to weaken plants so subjected. The Ipomæa may be cut back to some prominent eyes, the nearer the root the better. You may do it now, but you must allow the plant a period of rest. Three months are not too long, yet it does moderately well after a rest of six weeks. The longer the roots rest the stronger growth and finer bloom may be expected from them.

HOT-WATER PIPES AND ROOTS (*Old Subscriber, Nottingham*).—The pipes should be at least 1 foot from the stems of your Peach trees. Three inches is too near the stems to place hot-water pipes. From 9 inches to 1 foot is the distance we recommend in your case. Vine roots are situated at about 1 foot from the surface, some deeper and some shallower; but, as a rule, in well-made borders they do not run deeper than 20 inches, whilst in some cases they penetrate to a depth of 4 feet.

BROXMOOTH GRAPE (*J. F.*).—As the Fruit Committee were not requested to do more than say whether or not they considered Mr. Denham's Grape the Muscat of Alexandria, they did not express any opinion upon its identification. It would, indeed, have been impolitic to have done so in the absence of further information, and of seeing the fruit growing on the Vine. There is reason, however, to believe that it is the true White Tokay; but upon this point it would be useless to assert anything without having had an opportunity of examining it thoroughly.

ALOCASIA MACROSPHA VARIATA PROPAGATING AND MANAGING (*One of the Try Company*).—It is propagated from suckers. These rise near the stem of the old plant. The soil is removed down to where the sucker rises from the root, and the latter is there cut off with a sharp knife, taking the least touch of the old root along with it. This operation is best done in the process of repotting the old plant. Use very turfy peat and loam from rotted turves half, leaf mould a quarter, and bits of charcoal (broken fine for cuttings, and not larger than a hazel nut for established plants), and silver sand the remainder. In this the cuttings are placed, if very small, in 60-sized pots, and the others in a larger size, just sufficient to hold them without cramping. A gentle watering is given, and the pots being plunged in a mild bottom heat of 75° to 80°, place a bell-glass over them. Keep close and shaded for a few days, and the suckers will soon become established. Gradually harden-off and grow on in the stove, potting as often as the plants fill the pots with roots. Perfect drainage is essential, and a moist close atmosphere must be maintained to have the plant in perfection. It is hardly possible to give it too much encouragement; therefore the shifts should be frequent, the watering copious, no dribbling but a thorough wetting. It must be shaded from strong sun, and kept as near the glass as its size will permit. In future pottings the charcoal should be more plentiful, using less sand—in other respects the compost recommended for raising the plants is suitable. A winter temperature of 60° to 65° at night, with a rise of 10° to 15° by day, and one in summer of 70° to 75° by night, and 85° to 90° by day, will grow this plant something like a monstrous Victoria Rhubarb plant with leaves nearly a yard across. Plenty of moisture, a sweet atmosphere, and a high temperature, with plenty of pot room, are the main points in its cultivation.

SPHEBOGYNE LATIFOLIA PROPAGATING AND MANAGING (*Idem*).—This is propagated from cuttings of the half-ripened shoots. If the cutting has three joints, one below, inserted in the soil, and another above, with the apex or growing point, they are just the sort. These, inserted singly in small pots in a compost of peat and silver sand, root rather freely in a bottom heat of 75° to 80° with a bell-glass over them. They will be well rooted in about six weeks, when they should be hardened a little prior to their being placed in the stove. The heat of an ordinary stove suits it. The plant requires a moist atmosphere, and shade from very bright sun. A compost of turfy peat half, light turfy loam and leaf mould in equal parts of the remainder, with a liberal admixture of silver sand is the most suitable soil. Perfect drainage must be provided, and the plants require potting when the pots become full of roots.

VINES, PEACH-HOUSES, &c. (*C. Peel*).—In articles by Mr. Thomson, Mr. Fish, and others you would see much on the arrangement of houses, and there is also much particular matter at page 400 in answer to correspondents. With such a *carte blanche* as you give, and no particulars, we might rewrite a volume and then not meet your individual case. See description of houses at Keels and Trentham. We think your first house will do very well. We presume the roof has a steep slope. A steep roof is also best for late Grapes. Your late house should be allowed to break naturally, or rather be kept back from breaking. It will need fire heat chiefly when the Vines are in bloom, and then in the autumn and winter to keep the Grapes from damping. These are the cheapest Grapes, and, perhaps, the most useful, as they come in when other fruits are scarce. Fine plants are grown in lean-to houses, but span-roofed houses are best—unless in cold northern districts, when a wall on the north side, or part of the north side so as to make a hipped roof, is an advantage merely on the score of warmth. Where fuel is plentiful the span roof is the best and most convenient.

CLIMBERS FOR WALL (*W. B.*).—*Lonicera aureo-reticulata*; *Pyrus japonica*, ditto white; *Passiflora coriacea*, and *P. Neumannii*; *Wistaria sinensis* and *alba*; *Magnolia grandiflora*; *Lonicera brachyrrhoda*, flexuosa, and fragrantissima; *Jasminum nudiflorum*, officinale, revolutum, and *Wallichianum*; *Aristolochia siphio*; *Bignonia grandiflora*, *B. radicans* major; *Clematis azurea grandiflora*, *C. flammula*, lanuginosa, odorata coriacea, and Sieboldi; *Atragene austriaca*. In addition to these there are numerous climbing Roses.

FLOWERING SHRUBS OF LOW GROWTH (*Idem*).—*Andromeda floribunda*, and *formosa*; *Berberis* of sorts; *Althæa frutex*; *Tree Pæony*, many kinds; *Buddleia globosa*; *Potentilla floribunda*, and *fruticosa*; *Cistus*, several varieties; *Cytisus* in variety; *Deutzia gracilis*, *grandiflora*, and *scabra*; *Daphnes*; *Furze* (double); *Lycasteria formosa*; *Ribes aureum*, sanguineum, var. *album*, and var. *atropurpureum*; and *Spiræas* in great variety.

EYEDREEN FOR CENTRE OF BEDS (*Idem*).—*Cupressus Lawsoniana*, *Juniperus stricta*, and *Thuja aurea*. The last we think would answer your purpose better than Bay trees, which are not hardy everywhere.

SOIL FOR VINES IN POTS (*R. G. B.*).—We do not recommend pressing the soil very hard in making a Vine-border. The soil should be packed rather firmly together with the fork, but no treading or ramming must be allowed. The soil will become quite firm enough in time without any ramming or pressing. The author of the book you name is not the same person of the name that writes for this Journal. The book, however, is a good one.

REPORTING CALCULADIAS, &c.—LOBELIA PAXTONIANA (*Nescio*).—In your circumstances it would be as well to defer repotting until the change of the day—say the 1st of January, then give a small shift—say into seven or seven-and-a-half-inch pots. You cannot well strike the Lobelia now without more help than a cold frame. Encourage growth and take off cuttings as soon as you can get a little heat in spring. You might easily make a little propagating-box inside of your living-room. We cannot say where you can get Chrysanthemum seeds. The raisers are not likely to part with their best seed. They are raised easily from seed.

WINTERING GERANIUMS IN A CELLAR (*Notice*).—We prefer taking off the soft parts of Geranium-shoots, removing all the leaves, dipping the tops left in quicklime, and packing the roots in dryish earth, or moss neither dry nor wet, for keeping in a cellar. The great thing is to preserve vitality but to prevent growth.

CYATHEA DEALATA PINNULES TURNING BROWN (C. S. N.).—The tips of your Fern fronds may be brown from moisture lodging on them during the night, which is evaporated rapidly on the presence of light in the morning. Too little water at the root, a current of cold air, and too dry an atmosphere will also produce the same result. Your plant is kept at least 20° too warm. A temperature of from 40° to 50° is quite warm enough for this Fern in winter. We keep ours in a cool house from which frost is only just excluded, and it is little short of 6 feet high, and a very young plant. Try a cooler temperature and a more regularly moist atmosphere.

BACK WALL OF A VINERY (H. M.).—Never think of withholding from giving us trouble. Such letters inform us of what our subscribers want, and thus enable us to please them as we would like to do. But, of course, in order to be able to give general satisfaction our correspondents should make definite inquiries as you do, and even then send only few inquiries at a time, which we are sure they would do if they would recollect that there may be hundreds if not thousands in a similar position to themselves. We think you exaggerate in speaking of the "hardness of our knocks" even in such cases, for we never intend to do more than ask for moderation. We fully appreciate your object in desiring to keep your back wall as low as 6 feet, as few advantages are worth having that could be construed into a source of annoyance by a neighbour. We presume the whole of the border for the Vines is to be inside, and that for such a small house will be an advantage. We have no doubt at all as to the plan answering with your hipped roof at back. That hip could be binged to open, or you could have a double ridge and a space of 9 inches or so between them, with a cap to move as desired, or a ventilator could be suspended underneath the cap, and openings left on the side. The moving of the hipped roof would be the simplest. If you mean to move your sashes, the having three or even four bars would be much the best. If the house is on your own property why not have a fixed roof? Sash bars 1½ by 24 or 3 inches would be quite sufficient. We forget already about the point in the book you refer to; and here we suppose we must give a knock in the shape of a hint, that our friends must not suppose that we have long memories, so as to know where to turn for references without any figures of page or volume. We presume, however, that you mean to follow the plan of houses for the million. In such a case you will need little air at back; but 3 or 4 inches must be left between each sash, and the place covered by a ventilator, to be moved less or more at pleasure. If we can help more we shall be glad.

VINES UNDER SHEET-GLASS BURNING (E. P.).—Give plenty of air to the Vines, especially at the top, and a little the first thing in the morning. Then look over the glass carefully, and on every scar or node of any size, daub a little paint or liquid putty. In most cases the air will remedy the evil; but the knots, if at all large, will burn the leaves. They concentrate the rays of the sun to one point.

FORCING A ROW OF SEA-KALE (D. T. W.).—Clear away all the old leaves, place a cone of ashes over the heads of the Kale, cover with pots, boxes, or merely sticks and strawbands, dig out a slight trench on each side of the row, and fill the trench with hot fermenting dung. Cover all over with leaves or litter so hot that the enclosed space will have a temperature of about 60°, and not more. The heat at the roots may be a little more. We are supposing that you mean to force the row where it stands. If taken up a dark place anywhere, with an average heat of 60°, would do. For instance, make a slight hotbed, take up the plants and put them in it, and cover with an old box or chest turned topsy-turvy, or make a box of old slabs and cover all over. By this plan a barrowload of fermenting manure will do as much as a good cartload out of doors over the row. The Strawberry pots will do well in a cold frame; they will do so plunged in the border protected from severe frost, or built up as described in "Doings of the Week" last week. There is no hook on the questions you note equal to the lucid articles in this Journal. Mr. Fish commenced a series of such articles, but other matters have kept them in abeyance. You will find full particulars of all such matters in "Doings of the Last Week."

GREENHOUSE FOR WINTERING GERANIUMS, &c. (G. H.).—We could have advised better as to internal arrangements had you given us the height of the apex of the roof and height in front or sides altogether. Rough plate glass will be best for the roof at all times, and especially in summer. The sides may be done with common plate. If expense is an object, common plate about 2d. per foot will do well enough, and the light might be dulled in summer. See "Doings of the Last Week" the other week and description of Kettle Hall. The flue taken right through the middle of the house, and its top forming the pathway, would be the cheapest plan of heating. A small boiler and two pipes all round would be the best. If the roof is low a pathway down the middle—say 3 feet wide, and a bed on each side 4½ feet wide—would be the simplest mode of arrangement; but the plants at the sides could not be so well attended to or examined as if they were nearer to the hand and eye. To make the most of such a house—that is, to yield the greatest amount of gratification—we would have a shelf on each side, 18 inches wide, with the heating-pipes below as far as the doorway, the shelf also going round the farther end, then a walk all round of 2½ feet, and a table or platform in the centre of 4 feet. This might be flat, or you might make it into a stage with a raised shelf in the centre, and two or three on each side. It would have been better if the house had stood north and south, but it will do very well as it is. The raised stage would, perhaps, be best if the apex of the roof were as much as 10 or 12 feet in height. A vast number of things could be housed under such a stage in winter.

NAMES OF FRUITS (Star).—The Pear is Wormsley Grange, and the Apple Colonel Vaughan. (*A Reader, Banffshire*).—2, Poiré de Rance; 3, Ne plus Meuris; 5, Figue de Naples, will not do so far north; 6, Chaumontel. Others not known.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE BIRMINGHAM TEN-SHILLING DAY.

THE following paragraph in your paper of last week, quoted from *The Midland Counties Herald*, cannot fail to excite astonishment and suspicion:—"This year the public will be admitted on Saturday the 28th inst., the day on which the Judges make their awards. The reason for this innovation is, that some exhibitors have expressed dissatisfaction that

the judging should be conducted in private, and the Council have, therefore, determined to give the privilege on payment of an admission-fee of 10s. It was deemed necessary to fix the admission-fee thus high in order that the Judges might not be impeded by a throng in the performance of their arduous duties, and also not to interfere with Monday, the day of the private view. The poultry, however, will not be exhibited until Monday."

The necessity for public judging presupposes dishonesty on the part of the Judges, but it is a question whether under any circumstances the remedy is not worse than the disease. Under the circumstances above quoted it is a positive dishonesty. Either the judging should be public and all exhibitors admitted by special tickets, or it should be private and all exhibitors excluded. The admission of a few for a fee of 10s. implies either weakness or unfairness on the part of the Council. They are either overawed by the wishes of "some exhibitors" who have expressed dissatisfaction, or else, for some reason best known to themselves, they wish to give an unfair advantage to "some exhibitors" who are disposed to pay for it. It is in effect the golden key to be used without secrecy. The reason given, that it is to avoid inconvenience to the Judges is simply a sham. There is as much inconvenience to a Judge from fifty excited and privileged exhibitors as from a hundred.

Let me ask the Council if they will permit me to make any alterations in my entries. They certainly will not. Why, then, should they make any change in the regulations under which those entries were made? I certainly would not have entered anything at Birmingham had I known of this 10s. privilege, and I protest against such a breach of faith as to subject me either to a tax of 10s. or to the loss of a privilege which may be used very materially against me. The meaningless remark that "the poultry will not, however, be exhibited until Monday," neither throws poultry exhibitors out of court nor guarantees their safety. It does not even say that the same principle will not be applied to that department. Perhaps it is intended to delude the unwary into such a supposition; but if the principle be admitted into one part of the Show, what is to prevent the Council by a stroke of the pen granting the already privileged "upper ten shillings" another privilege?

This decision of the Birmingham Council amounts to an admission that the Judges are dishonest, whilst it toadies to the wishes and interests of "some exhibitors." I am inclined to say, despite this Birmingham admission to the contrary, that the Judges at the great shows are men of strict honour, and I do not know why this mead of praise should not be awarded to those of smaller exhibitions. I am quite willing to admit that there are Judges who sail under false colours, who are swayed by influence and self-interest, and care little for the results. I do not believe that public judging will prevent this. There is as much to fear from the excited interference or impeding (as the *Midland Counties Herald* calls it) of exhibitors, as the deliberate unfairness of Judges. How an honest Judge can fairly and exactly decide the merits of a multitude of pens or exhibits of nearly equal merit in a crowd of exhibitors of every variety, I cannot tell. I do not believe that an iron-nerved man could do it well; a nervous and very conscientious man would inevitably be flurried, and peculiarly liable to mistake.

If the Birmingham principle is tolerated for a moment it may, and probably will, spread to other shows, and then the groans of your correspondent, "AN EXHIBITOR IN A SMALL WAY," may have some foundation. Those who cannot be present, and those who do not choose to pay, will grumble that their interests should have been watched by the "upper ten shillings." I am determined to have something for my money, and anticipate a treat, which I may communicate to you.—EGOMET.

BREEDING EARLY CHICKENS.

THOSE who breed early chickens—and whether for exhibition or the table, we think they are wise who do so—will now begin to prepare their pens, and to select their breeding-stock. It is not too early to do away with the promiscuous running that prevails in most yards during the

autumn. The period of separation has not been certainly defined, nor the time that must elapse after the running together of all breeds before the produce of a pen can be depended upon. In our opinion, if eggs are to be set in January, the birds should now be all separate. It is unpleasant to find when the hen comes off that the Spanish have an indisputable relationship to Dorking; and that there is more than suspicion there has been a *mésalliance* between Hamburgs and Cochins. This early separation may involve, perhaps, a little more daily labour, as birds in confinement must give more trouble, if they are properly tended, than those that are at liberty. Where, however, they are judiciously treated, and the supply of food, &c., is assimilated as nearly as possible to that they would get in a state of nature, we are not sure that fowls, with the exception of one or two breeds as Dorkings, are not as well in good roomy pens open to the sun as they are at liberty during the midwinter months, when the ground is barren of food, and the night occupies two-thirds of the twenty-four hours.

Our motive for treating this question is the number of queries we have at this season of the year, asking how long fowls of different breeds that have been running together should be separated before their eggs may be depended upon. It is a vexed and undecided question; but seeing that failure is irremediable during the current season, and that January or February chickens can only be hatched in those months, we advise immediate separation. The pens should be made afresh. All the holes and dusting-places the fowls have made during the summer and autumn should be filled up, and the surface levelled in such a way that the water shall run off during the winter. A good mound of sand should be made in a sheltered spot. If road-grit can be had, so much the better. It is always dry, and the fowls like it much. It is the best material we know for pens.

HULL EXHIBITION OF POULTRY.

It required a considerable display of resolution to carry out a Poultry Show at Hull, with a probable amount of success, at a date just preceding the Shows now so nearly approaching at Birmingham, Brighton, Leeds, Darlington, Manchester, and a host of minor meetings of like character. Yet none who visited the Hull Meeting on the 18th inst. could express a contrary opinion, than that as a whole it was a good one. It was evident, even at first sight, that chickens just at this time of year have great advantages over the old birds for exhibition purposes, and will do so for the next month to come. This was apparent in every class where such entries competed together. In Game fowls this superiority was necessarily even more developed than in some of the other breeds. Old Game cocks are not, as yet, sufficiently recovered from their moult to handle with the firmness of feather required; the young plumage being still in most cases only partially matured, and the pen feathers so full of sap, as to tend greatly to encourage the cannibal-like propensity, to which Game fowls especially are most prone, of actually eating each other piecemeal. We noticed several birds that were suffering from this morbid habit, and that, though evidently enduring intense pain, offered but little opposition to their mates, even though the flesh was actually being torn atom by atom from the bone. It is well just to remind amateurs, that fowls having once contracted this vitiated taste for flesh and pen-feather are rarely so far broken of the destructive habit as to be trusted again in close confinement, also that the injured birds in very few instances ever recover their plumage in perfection. It is, therefore, a rule that may be considered as universal with all kinds of fowls—they should never be closely confined till the feather is hardened, as well as replaced, or the bad policy of sending them to shows in that condition can only entail both loss and disappointment.

At the Hull Meeting the whole of the labour part of the affair lay on sadly too few hands, for, as at too many shows, the Committee seemed to dwindle into the smallest limits, when work, absolute "putting the shoulder to the wheel," most required it. This is a failing very generally complained of on all sides, and we think the promise "to help," ought to be scrupulously observed (or withheld) at the time

of the first formation of any poultry committee meeting. Another hint to exhibitors may here be usefully enforced—viz., strict compliance with the rules of the prize schedule issued solely for their direction by each Society. The intending exhibitor should in every case give this an attentive perusal, as different rules are enjoined by different Societies. Want of attention to this point alone caused several pens to be at once "disqualified" at Hull, among which was most decidedly the best pen of Grey Dorkings in the whole Exhibition. It must be borne in mind, that exhibiting a hen too many is equally fatal to success as one too few. We shall confine our remarks to a few of the best specimens at the Hull Meeting.

The cock (a Brown Red) in the *Game* class for a cock and one hen, was, perhaps, one of the most perfect birds in the Exhibition, and shown in condition, such as we generally find from the yard of Mr. Harry Adams, of Beverley. Being "a stag," no doubt his triumphs will be extended to other shows. The *single Game cock* class was not equal to anticipation; indeed, it was difficult to find birds worthy of prizes, even the first prize bird (otherwise a model of perfection) was suffering from an old injury to an eye; and the second-prize cock, a Black Red, that last year gained so many premiums for its well-known owner, Mr. Julian, has this year moulted so radically untrue to feather, that his continued success is impossible where anything at all approaching competition arises. In *Hamburgs*, it is only a rare exception that we meet with classes so good as were both the varieties of Spangled. These were one of the most striking features of the Show. An exquisite pen of Brown Red *Game Bantams*, the property of Mrs. Sharp, well deserved the most favourable mention. Some remarkably good *Polands* were shown.

In *Geese*, *Turkeys*, and all classes of *Ducks*, the Hull Show stood high. The Buenos Ayrean Duck class was not only well filled, but the competition was throughout of the highest order. Mr. Jessop, of the Beverley Road, here held his own against all comers.

The classes for *Pigeons* were not only numerous filled, but also with the choicest specimens. This feature of the Show was, however, robbed of much of its public interest, by all the birds being placed decidedly too high for inspection; but we hear another season this cause of complaint will be remedied.

The introduction into the prize schedule of "selling classes," with prizes, as in other cases, at Hull, proved quite a success. No kind of restriction of age or breed was enforced, the only proviso being a limit as to the selling price—in the fowls to 30s. the pen, and in the Pigeon class to 15s. the pen. A capital competition ensued, with choice the most abundant as to varieties, whilst the limited sums at which they were entered insured change of ownership to not a few pens. Again, the commission on sales to the Society was the same as on all others. The Hull Committee having thus introduced this new feature, no doubt other shows will also carry it into practice successfully.

DORKINGS.—First, W. H. Robson, Louth. Second, J. Dixon, Bradford. Highly Commended, J. Dixon.

SPANISH.—First, S. Robson, South Milford. Second, T. Greenwood, Dewsbury. Commended, H. Beldon, Bingley; E. Brown, Sheffield; W. Bowly, Cirencester.

COCHIN-CHINA (Cinnamon and Buff).—First, E. Smith, Middleton. Second, T. H. Barker, York. Highly Commended, W. Bradley, Worcester; C. R. D'Ewes, Knaresborough.

COCHIN-CHINA (Any other variety).—First, G. Williamson, Nantwich. Second, E. Smith. Highly Commended, W. Dawson, Hopton Mirfield.

GAME (Black-breasted and other Reds).—First, H. Adams, Beverley. Second, Rev. F. Watson, Norfolk. Highly Commended, H. Adams, Beverley. Commended, W. J. Cope, Barnsley; J. Hodgkinson, Salthouse Lane, Hull; M. Mantle, Newark.

GAME (Any other variety).—First, F. Sales, Crowle. Second, W. J. Cope, Barnsley (Duckwing).

HAMBURGHS (Golden-pencilled).—First, J. Dixon, Bradford. Second, S. Smith, Halifax. Highly Commended, H. Pickles, jun., Skipton; Mrs. Jessop, Hull.

HAMBURGHS (Silver-pencilled).—First, H. Beldon, Bingley. Second, J. Platt, Dean. Highly Commended, A. Nicholson, Walkley, Sheffield; W. Cannan, Bradford.

HAMBURGHS (Golden-spangled).—First, J. Newton, Leeds. Second, J. Roe, Manchester. Highly Commended, H. Beldon; H. W. B. Berwick, York; W. Cannan, Bradford; G. Holmes, Driffield.

HAMBURGHS (Silver-spangled).—First, H. Beldon, Bingley. Second, H. Pickles, jun. Highly Commended, W. Cannan; J. Dixon, Bradford; J. Newton, Leeds. Commended, H. Bancroft, Staunton.

POLISH (Any variety).—First and Second, J. Dixon, Bradford. Highly Commended, R. M. Stark, Hull. Commended, H. Beldon, Bingley; D. Hollingworth, Otley.

ANY OTHER DISTINCT OR CROSS BREED.—First, H. Beldon, Bingley. Second, W. Dawson, Hopton Mitheld (Crève Cœurs). Highly Commended, E. Greenwood, Burnley (Brahmas). Commended, J. Dixon, Bradford (Black Hamburgs).

BANTAMS (Game).—First, Mrs. Sharp, Bradford. Second, E. Brown, Sheffield. Highly Commended, W. Lawrenson, Derby; Mrs. Perren, Hull; C. W. Brierley, Manchester; J. W. Morris, Rochdale. Commended, R. Smith, Hull; J. Dixon, Bradford.

BANTAMS (Gold or Silver-laced).—First, H. Beldon Bingley. Second, J. Dixon, Bradford. Highly Commended, R. M. Stark, Hull (Silver); C. W. Brierley, Manchester.

BANTAMS (Any other variety).—First, W. J. Cope, Barnsley (Pekin). Second, H. Beldon (Black). Commended, R. Gledhill, Bradford (Black).

GANDER AND GOOSE (Any variety).—First, J. Dixon, Bradford. Second, O. A. Young, Driffield. Highly Commended, O. A. Young.

TURKEYS (Any variety).—First, R. M. Stark, Hull. Second, J. Dixon, Bradford. Highly Commended, E. Leech, Rochdale.

DUCKS (Aylesbury).—First, E. Leech, Rochdale. Second, R. M. Stark, Hull. Highly Commended, O. A. Young, Driffield; E. Leech; J. Dixon, Bradford; J. Middlehurst, jun., St. Helens.

DUCKS (Rouen).—First, H. Beldon, Bingley. Second, E. Leech, Rochdale. Highly Commended, E. Leech. Commended, J. Dixon, Bradford.

DUCKS (Black East Indian).—First and Second, J. R. Jessop. Highly Commended, F. W. Earle, Prescott; Master F. Sngden; R. M. Stark, Hull; J. Dixon.

DUCKS (Any other variety).—First, J. Dixon, Bradford (Grey Call). Second, Mrs. Jessop, Hull (Wild). Highly Commended, W. H. Young, Driffield (Muscovy).

GUINEA FOWL (Any variety).—First, O. A. Young, Driffield. Second, R. Voakes, Driffield.

GAME COCK (Any age or colour).—First, H. M. Julian, Beverley. Second, W. Boyes, Beverley. Third, H. Adams, Beverley.

GAME BANTAM COCK (Any age or colour).—First, R. M. Stark, Hull. Second and Third, R. Smith, Hull.

COCK OF ANY OTHER DISTINCT BREED.—First and Third, E. Leech, Rochdale (Brahma and Malay). Second, R. R. Tulip, Mowkwearmouth (Spanish).

SELLING CLASS (Any age or variety).—First, O. A. Young, Driffield (Polish). Second, J. Crookes, Sheffield (Silver-spangled Hamburgs). Third, C. Verity, Beverley. Highly Commended, H. M. Julian, Beverley (Game). Commended, H. Beldon.

PIGEONS.

CARRIERS.—First, J. Firth, Dewsbury. Second, S. Robson, South Milford. Highly Commended, Mrs. Statters, Hull; W. Watson, Beverley; H. Yardley, Birmingham; J. W. Edge, Birmingham; C. J. Samuels, Manchester.

ALMOND TUMBLERS.—First, H. Beldon, Bingley. Second, C. N. Lythe, Cottingham. Highly Commended, H. Yardley, Birmingham; J. E. Firth, Hull.

TUMBLERS (Any other variety).—First, H. Yardley, Birmingham. Second, W. Taylor, Sheffield. Highly Commended, J. R. Jessop, Hull (Splashed); J. Bell, Newcastle-on-Tyne (Kites). Commended, E. Leeson, Driffield; W. Carlton, Howden.

POWERS.—First, S. Robson, South Milford. Second, W. Taylor, Sheffield. Highly Commended, H. Beldon, Bingley; H. Yardley, Birmingham; W. Taylor. Commended, H. Brown, Sheffield; J. W. Edge, Birmingham.

JACOBS.—First, H. Yardley, Birmingham. Second, W. Veitch, jun., Jedburgh, N.B. Highly Commended, T. Ellington, Woodmansey. Commended, J. Percival, Peckham; H. Brown, Sheffield; C. W. Brierley, Manchester; J. W. Edge, Birmingham.

FANTAILS.—First, T. C. Taylor, Middlesborough. Second, J. R. Jessop, Hull. Highly Commended, H. Yardley, Birmingham. Commended, H. Brown, Sheffield; J. W. Edge, Birmingham.

TRUMPETERS.—First, H. Yardley, Birmingham. Second, J. R. Jessop, Hull. Highly Commended, S. Robson, South Milford; W. Veitch, jun., Jedburgh, N.B.; R. Carrick, Preston. Commended, W. Carlton, Howden; J. W. Edge; C. J. Samuels.

BARES.—First, H. Yardley, Birmingham. Highly Commended, J. J. Stott, Rochdale; J. R. Jessop, Hull; S. Robson, South Milford; H. Yardley; C. J. Samuels, Manchester.

TURBIS.—First, T. C. Taylor, Middlesborough. Second, W. Massey, Wisbeach. Highly Commended, M. E. Jobling, Newcastle-on-Tyne; H. Beldon; J. W. Edge.

OWLS.—First, H. Beldon, Bingley. Second, H. Yardley, Birmingham. Highly Commended, F. Else, Bayswater; H. Yardley.

NUNS.—First, B. Leeson, Driffield. Second, J. W. Edge, Birmingham.

ANY OTHER VARIETY.—First, J. R. Treuan, York (Spots). Second, H. Yardley (Saturnettes). Highly Commended, T. D. Green, Saffron Walden (Bunts); M. E. Jobling, Newcastle-on-Tyne (Swallows); J. U. Somner, Jedburgh, N.B. (Victorias); J. Wade, Leeds (Runts); C. J. Samuels.

SELLING CLASS (Any variety).—First, J. W. Edge, Birmingham (Swallows). Second, F. Key, Beverley (Trumpeters). Third, W. F. Watson. Highly Commended, W. Massey, Wisbeach; J. Percival, Peckham; J. Bilton, Cottingham. Commended, J. Statters, Hull.

Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, was the Judge.

A THRICE-TOLD TALE.

This is our last Number previous to the great assize at Birmingham. We repeat that which we have so often said to exhibitors, Send your fowls in good time that they may be unpacked and fed by daylight; those who send late, and their name is Legion, throw away one chance of success, and double the labour of the Committee. Accustom the birds that are to be shown together to close contact. See that they agree; it is one thing to run together in a yard, and another to be shut up in a small pen. Wash their legs and faces if necessary. Put them in a roomy

basket, in which even the cock can stand up. Let them have clean straw at the bottom, and feed them before starting with soft food, meal mixed slack, or bread and water or milk.

NORFOLK AND NORWICH ORNITHOLOGICAL SOCIETY.

THE second Exhibition of Canaries, British and foreign birds, poultry, Pigeons, &c., in connection with the above Society, was held at the New Corn Hall, Norwich, on the 3rd, 4th, and 5th inst. The following are the awards:—

CANARIES.

NORWICH (Clear Yellow).—First and Second, S. Waters, Ipswich. NORWICH (Clear Buff).—First, S. Waters. Second, T. Mansfield, Norwich.

NORWICH (Marked or Variegated Yellow).—First, S. Waters. Second, J. Webster, Norwich.

NORWICH (Marked or Variegated Buff).—First, D. Grice, Norwich. Second, G. Reeve, Norwich.

NORWICH (Clear Yellow or Marked Crested).—First, H. Sexton, Norwich. Second, W. Adkin, Norwich.

NORWICH (Clear Mealy Crested).—First, H. Sexton. Second, J. Haydon, Norwich.

CINNAMON (Yellow).—Prize, G. Collinson, Yarmouth. CINNAMON (Mealy).—First, T. Irons, Northampton. Second, C. Eetts, Norwich.

YARMOUTH (Clear Yellow).—First, G. Collinson. Second, S. Stafford, Great Yarmouth.

YARMOUTH (Clear Buff).—First, S. Stafford. Second, G. Collinson. YARMOUTH (Marked Yellow).—First, S. Stafford. Second, G. Collinson. YARMOUTH (Marked or Variegated Buff).—First and Second, J. Cox, Great Yarmouth.

BELGIAN (Clear Yellow).—First, G. Harding, Ashton-under-Lyne. Second, G. Goodwin, Derby.

BELGIAN (Clear Buff).—First and Second, G. Hardy. BELGIAN (Marked or Variegated Yellow).—First, O. Nicholson, Fareham. Second, G. Goodwin.

BELGIAN (Marked or Variegated Buff).—First and Second, G. Goodwin. CLEAR YELLOW OR MARKED CRESTED.—Prize, G. Harding.

CLEAR MEALY OR MARKED CRESTED.—First and Second, G. Harding. LIZARD (Silver-spangled).—First, — Phillips, Nottingham. Second, — Waller.

LIZARD (Golden-spangled).—First, — Waller. Second, G. Goodwin. CAGES OF SIX (Open).—First, T. Madge, Norwich. Second, T. Mansfield, Norwich. Third, J. Webster.

GOLDFINCH MEAL (Mealy).—First, S. Waters. Second, W. Lincoln, Norwich.

GOLDFINCH MEAL (Jonque).—First and Second, S. Waters. LINNET MEAL (Mealy).—Prize, J. Lingard, Ashton-under-Lyne.

ANY OTHER VARIETY OF MEALS.—Prize, Dr. Guy, Norwich. BRITISH BIRDS.—Bulfinches.—Prize, J. Knibb, Northampton. Chaffinches.—Prize, J. Sayer, Norwich. Goldfinches.—Prize, H. Howlett, Norwich. Linnets.—Prize, S. Green, Norwich. Skylarks.—Prize, S. Waters. Blackbirds.—Prize, J. Sayer, Norwich. Song Thrushes.—Prize, J. Sayer. Starlings.—Prize, J. Sayer. Magpies.—Prize, J. Sayer. Any other variety.—Prize, J. Sayer. Black Chaffinches.—Prize, J. Sayer. Nightingales.—Prize, J. Rose, Norwich. Siskin or Aberderine.—Prize, S. Waters, Ipswich.

FOREIGN BIRDS.—Parrots (Grey).—Prize, J. Sayer. Parrots (Green).—Prize, J. Rose. Parquets (Australian Grass).—Prize, J. Rose. Parquets (Ring-necked).—Prize, Capt. Warnes, Marsham. Any other variety.—Prize, J. Rose, Norwich (Quaker). Rosetail Parquets.—Prize, Capt. Warnes, Marsham. Pennant's Parquets.—Prize, Capt. Warnes. Cockatoos (Sulphur or Lemon-crested).—Prize, J. Calver, Norwich. Cuckatoos (Black or Any other variety).—Prize, R. Mackley, Norwich. Java Sparrows.—Prize, C. Betts, Norwich. Zebra War Bills.—Prize, J. Rose. War Bills (Any other variety).—Prize, S. Waters. Any other variety of Foreign Birds.—Prize, Mrs. Steward, Great Yarmouth.

POULTRY.

SPANISH (Black).—Prize, T. Loomie, Norwich. (Not so good a class as might have been.)

DORRING.—First, J. Monsey, Norwich. Second, J. Frost, Norwich. Highly Commended, J. Lingard, Ashton-under-Lyne; J. Smith. (Capital class; superior birds.)

DORRING (White).—First, Rev. F. Hodson, Bridgewater. Second, J. Liogard.

COCHIN-CHINA (Cinnamon or Buff).—First, Rev. C. Spencer, Attleborough. Second, Rev. C. Gilbert, Yarmouth. Highly Commended, Mrs. Dawson, Norwich; Rev. C. Spencer. (Good class.)

COCHIN-CHINA (Brown or Partridge-feathered).—First, Rev. F. Hodson, Second, J. Wright, Woodbridge. (Good class.)

COCHIN-CHINA (White).—First, H. Bagge, Stoke Ferry. Second, Col. Cockburn, Norwich. Highly Commended, Col. Cockburn.

GAMES (White and Piles).—First, J. Monsey, Norwich. Second, S. Matthews, Norwich. Highly Commended, T. Pares; T. Rix. (Good class.)

GAME (Black-breasted Reds).—First, J. R. Kersey, Winston. Second, T. Rix. Highly Commended, Capt. Bignold, Norwich; W. Dowling, Suffolk; J. Monsey, Norwich. (Some superior birds among them.)

GAME (Duckwings and other Greys and Blues).—First, S. Matthews, Norwich. Second, J. Monsey, Norwich. Highly Commended, W. Pares, Derby.

HAMBURGH (Golden-pencilled).—Prize, Rev. T. L. Fellowes, Beighton Rectory.

HAMBURGH (Silver-pencilled).—First, J. Monsey, Norwich. Second, Rev. T. L. Fellowes, Beighton Rectory.

POLAND (Black, with White Crests).—Prize, R. Stark, Hull.

POLAND (Gold).—First, Withheld. Second, J. Wright, Woodbridge.

POLAND (Silver).—Prize, J. Wright, Woodbridge.

ANY OTHER DISTINCT BREED.—First, J. Monsey, Norwich (Malay). Second, J. Wright, Woodbridge (Brahma Footra). Highly Commended, H. Bagge, Stoke Ferry (Andalusian); S. Waters, Ipswich (Crève Cœur). Commended, Rev. T. L. Fellowes; W. Pares, Derby. (Some very superior birds shown in this class.)

BANTAMS (Gold-faced).—First, Rev. F. Hodson, Bridgewater. Second, J. Monsey, Norwich. Highly Commended, R. Stark, Hull. (Very good class.)

BANTAMS (White, with Clean Legs).—First, J. Monsey, Norwich. Second, R. Stark, Hull.

BANTAMS (Black, with Clean Legs).—First, J. Monsey, Norwich. Second, Rev. F. Hodson, Bridgewater. Commended, Rev. F. Hodson. (Very good class.)

GAME BANTAMS (Black or Brown-breasted Reds).—First, J. Monsey, Norwich. Second, J. Wigg, Woodbridge. Highly Commended, J. Wigg; S. Waters. (Some extraordinarily good birds; Mr. Monsey's the best we ever saw.)

BANTAMS (Duckwing).—First, G. Collinson, Yarmouth. Second, S. Waters, Ipswich. Highly Commended, J. Monsey, Norwich. Commended, G. Collinson, Yarmouth. (Good class.)

BANTAMS (Any variety).—First, O. Nicholson, Fareham, Hants. Second, A. G. Cae, Southwell, Notts. Highly Commended, J. Whaites, Norwich.

PIGEONS.

CARRIERS.—First, J. Whaites, Norwich. Second, R. Mackley, Norwich. Highly Commended, W. Reynolds, Yarmouth.

HERNS OF ANY COLOUR.—First, W. Raby, Norwich. Second, J. Whaites, Norwich.

CARRIERS (Black and Dun).—Prize, J. Whaites, Norwich.

ALMOND TUMBLERS.—First, S. H. Meachen, Norwich. Second, — Summers. Highly Commended, S. H. Meacheo; W. Simmonds, Yarmouth.

ANY VARIETY NOT BEFORE MENTIONED.—First, Mrs. Craigie, Chigwell (White Barbe). Second, J. Monsey, Norwich (Isabela). Highly Commended, Mrs. Craigie (Ruots); J. Chase, Yarmouth (Black Priests).

(Pigeons not so good as might have been).

JUDGES.—Canaries: Messrs. W. Copeman, J. Nichols, and Breeze. British and Foreign Birds: Mr. Robert Thorns. Poultry and Pigeons: Mr. J. Martin, Linton Park, Staplehurst, Kent; and Mr. N. Sykes, jun., Globe Road, London.

MICROSCOPIC EXAMINATION OF FOUL BROOD.

THE above rough sketches are the result of an investigation into a disease named by apiarians "foul brood," which foul brood is the dying of some of the larvæ or young bees in the cells before the covering of the cells is ruptured or broken by the young bees. The decomposed young brood forms a brown sticky or treacly mass, and this when carefully examined with a drop of distilled water under a very high power, a one-eighth or one-sixteenth, gives the above, the size of which is about one-twenty-four-thousandth or one-twenty-five-thousandth of an inch in the transverse diameter.

No. 1 are sketches of the animals as seen alive. The dark triangular centre of the larger figures appear to me to be shades thrown by the singularity of their bodies; but being so minute and their gradually shifting their position makes it very difficult to determine with certainty. The nest of the animals is semi-transparent, their movements a slight undulatory lateral motion.

In Nos. 2 and 3 the animals were dead. They were found in honey kindly furnished by Mr. Woodbury for examination. The honey he informed me had been heated, which in all probability destroyed the life of the animals. They seem here to have shrunk up, and most of them had lost their tails and appeared like the upper figure and opaque, or nearly so, except the two wing-like processes on the side.

The No. 2 are very curious, and suggest the idea of an outline figure of the Hose-in-hose Polyanthus, or some of the Sertulariæ amongst the Corallines. Can this be its mode of propagation? It certainly appears very like it, and if so is apparently carrying out the great mode of propagation by fission like most, if not all, of the lower forms of animal life.

The affinity of these animals to others, or their place in nature, I must leave for future study; for, being creatures so minute, it is very difficult to assign to them their position amongst the multitudinous forms of microscopic animal life.—EDWARD PARFITT, *Devon and Exeter Institution*.

DRIVING BEES.

So many inquiries reach me from correspondents who have failed in driving and uniting bees, that I deem it worth while to enter upon the subject at some length, and fully to describe what I have found the best mode of effecting the desired object.

Let no successful operator deride or underrate the difficulties which often beset the novice in his first attempts at driving bees. I say often, but not always—in some few instances success is attained at once, as it were by a fortunate inspiration, and one successful operation generally begets so much confidence that all subsequent difficulties are readily overcome. Such was, I believe, the case with that accomplished apiarian "B. & W." when under the *nom de plume* of "A COUNTRY CURATE" he first delighted myself, in common with the other readers of the earlier volumes of the then COTTAGE GARDENER, by the interesting and graphic details of his earlier experiences contained in the "History of an Apiary." With myself, however, the case was far different, and it was only after many ineffectual attempts that I at length succeeded so recently as the summer of 1859 in first driving a stock of bees. Since that time my practice in this way has been very extensive, and as experience has led me slightly to modify my original proceedings, I am not without hope that by giving full details I may succeed in smoothing the path of some who may be desirous of mastering the art of driving, whilst they have no apiarian friend who is competent to instruct them by his example, which in this case especially is better, far better, than precept.

Driving bees should always be performed in the daytime, and the beginner had better wear a bee-dress and stout gloves;* but the only absolutely essential implements are a couple of empty hives (one of which should be of the same diameter as the hive to be operated on), an empty bucket, a long piece of stout linen (a roller-towel with the seam ripped answers admirably), a sufficient length of large twine, and a lighted fumigator or cigar, or some smouldering linen rags.

The bucket having been so placed as to stand firmly on the ground about a yard from the stock to be operated upon, a little smoke should be blown into the entrance. As soon as the bees retire the hive must be slightly raised from its floor-board and a few whiffs of smoke blown under it. Then raise the hive altogether from its place and steadily invert it on the bucket, covering it immediately with an empty hive of the same size, and closing the junction of the two by first winding the cloth round them, and then securing it by four turns of string, taking two turns round the upper and two round the lower hive. The bees within being thus safely ensconced, the second empty hive may be placed on the floor-board to amuse those returning from the fields, and the united hives with the bucket conveyed to a shady spot at a little distance. Here it will be found very convenient to have a couple of kitchen chairs, upon one of which the hives and bucket may be placed, whilst the operator seats himself on the other, and then a smart and regular rapping of the full hive with the palms of the hands should take place. In about ten minutes the great majority of the bees will generally be so alarmed as to quit their own hive and take refuge in the empty one—a fact which may be ascertained by listening to the noise made by them in ascending. At the expiration of the above-named period the cloth may be removed, and the hives sufficiently separated by raising one side of the upper one to admit of inspecting the interior. Few bees will be disposed to escape, and very rarely will they commence an attack. If nearly all have ascended into the hitherto empty hive, it may at once take the place of the decoy hive on the floor-board, and the full one may be

* A wide-mouthed bag of coarse black net, sufficiently large and long to envelope the head with a hat on, and reaching well below the neck, where it is secured by the coat buttoned over it, forms a very simple and efficient bee-dress. The best protection for the hands is a pair of Indian rubber gloves, such as are used by photographers.

conveyed in-doors, where the combs should be cut out, and the few remaining bees brushed off with a feather and returned to the apiary. If, on the other hand, many bees still adhere to their original domicile, or if, as is sometimes the case, only a few stragglers are found to have quitted it, the one side of the upper hive should be upraised a few inches and kept steadily in that position with the left hand so as to permit an unobstructed view of the interior, whilst the lower hive is rapped smartly with the right. Believing, as I do, that the jarring of the comb is the principal cause which impels the bees to ascend, I disregard the dictum of authority, and always rap on one side of the hive which is opposite to the sides of the combs, endeavouring so to regulate the force of my blows that whilst the vibration of the combs is so great that a bee can scarcely keep its footing on them, the concussion shall not be sufficient to detach them from their foundations. Such energetic measures admit of little delay on the part of the poor bees, a cry analogous to that of "*Sauve qui peut!*" speedily arises among them, as with vibrating wings and uplifted tails they "skeddadle" into the cheerless and ungenial shelter of an empty hive.

During this rush upwards, it is well to moderate the violent rapping into gentle tapping, just sufficient to keep the bees moving. If, as will probably be the case, the first exodus should not be sufficiently general, recourse must again be had to vehement rapping, and in this way a succession of panics may be produced until scarcely a bee remains in the hive. Should it be desired to catch and remove the queen, she may usually be found and secured by watching for her during the ascent. If she escape this scrutiny the congregated bees may afterwards be dashed out of the hive on a linen cloth spread on the ground, and compelled to run a short distance over the cloth to the empty hive, one side of which should be raised on a block an inch thick to allow them to enter freely. During this operation the queen may usually be found and secured; if not, it must be repeated until the desired end be attained. As bees will frequently refuse to remain in an empty hive when deprived of their queen, it is advisable to confine her in a small box made of perforated zinc, which may be firmly fastened to the top of the hive inside by means of a packing-needle and twine.

This is my mode of proceeding with ordinary straw hives, and it is on these that I should advise the novice to make his first experiments, selecting only strong stocks and well-filled hives. When he has been completely successful, and has attained sufficient confidence in his own powers, he may try his hand with wooden hives. In operating on these the cloth, string, and bucket may generally be dispensed with, but owing to the solidity of their material the vibration is so much less that bees do not so readily ascend, and a little more skill and patience are required.

In a future paper I hope to comply with the request of such of my correspondents as have desired information as to what modes of uniting bees have been proved the safest and most effectual by—A DEVONSHIRE BEE-KEEPER.

FOUL BROOD AND LIGURIAN BEES.

IN reply to "INQUIRER," I beg to state that foul brood has nothing whatever to do with the introduction of Ligurian bees. No foreign bees have ever been located within fifty miles of my apiary, which is composed of the common black bees, and yet one of my hives has this season fallen a victim to the disease. From whatever cause it arises, whether from a chill or something unknown which occasions an epidemic, every practical bee-keeper must feel deeply indebted to Mr. Woodbury for bringing foul brood under the notice of the public.

It exists in many localities where it was never suspected, and but for attention having been directed to the subject the writer can prove demonstrably that he would have lost a straw hive containing enough of honey to carry a medium swarm over two winters. Bees, in the case of foul brood, do not remove abortive brood in all stages. They remove chilled brood, but not invariably.

Look into any old hive, and you will scarcely miss seeing some cells—to use a little colouring—that have been

sealed up for ages. But let the cause be philosophically and candidly inquired into. I for one am grateful to Mr. Woodbury for the timely warning, which may probably lead to the preservation of a hive that would otherwise have inevitably perished.—AN ON-LOOKER.

MELILOTUS LEUCANTHA AND BEE FLOWERS.

HAVING for several seasons sowed some rows of *Melilotus leucantha* alongside my accustomed supply of borage, I am in a position to reply to the inquiry of Mr. W. C. Ellis, at page 384. I found the bees showed such a decided preference to the borage, to the almost total neglect of the *melilotus*, that for some years I have discontinued sowing it. It is a rank-growing plant, and its value as a bee-flower I quite agree with your correspondent is much over-estimated in some works. Borage, on the contrary, is eagerly sought after by the bees, and fed on even on wet days, should it be in close proximity to the apiary, the pendulous umbrella-shaped flowers affording shelter. Borage, a succession, *mignonette*, and a few beds of *nemophila*, are all the garden provision I am accustomed to make, besides, of course, an abundant supply of spring flowers—crocuses, hepaticas (single), and arabis. Bee-keepers would reap a much greater benefit by presenting the farmers in their neighbourhood with a few pounds of white clover per acre to sow as they lay down their pastures (should the land be at all favourable for its growth and they so neglectful of their interests as to omit doing so), than occupy much space with what are usually styled bee-flowers.—A RENFREWSHIRE BEE-KEEPER.

OUR LETTER BOX.

SPANISH COCK'S COME FALLING OVER (*R. L. W.*).—The comb may begin to fall from several causes. If the bird is from a strain with large fleshy, thick combs, they are carried over at the end by their own weight as soon as the birds attain a certain age and growth. In some cases the change from hard to luxurious living will cause undue development and a falling-over. In others it is part of the breed, and such combs are distinguishable by an indentation or hollow in front known as the thumb mark. Such never breed prize birds. As you say the comb was perfectly straight when you bought him it is probable it may return, if the change arises from the first cause; it is almost certain it will if it springs from the second. There is no hope from the third. Your Cochins inherit a crooked back; their ancestors were so before them. Nothing is so certainly transmitted as a crooked back. Either the cock or the hen requires to be changed. Perhaps both require to be got rid of.

COCHIN-CHINA BLIND (*Regular Subscriber*).—We are disposed to think, as you say the eye is perfectly clear, the blindness is only partial or temporary. We should advise purging with castor oil, a tablespoonful every other day. If that failed we would bleed at the back of the comb.

TOPKNOT OF BLACK POLANDS (*G. W. F. P.*).—It is a disadvantage, almost a disqualification, if a white topknot have black feathers intermixed with it. No topknot is free from some black in front, at least we never saw one, and it is bad policy to cut or trim it. But there should be no coloured feathers save in the front.

BEAK OF RED GAME COCK (*Idem*).—A yellow beak is not the necessary companion to yellow legs, although uniformity is always pleasing.

POINTS IN COCHIN-CHINA FOWLS (*Regular Subscriber*).—Our space will not permit us to give all the points, or a detailed account of Cochin cocks and hens. We will give the principal points, but for detail consult one of the many books on the subject. Round, sharp, intelligent heads; perfectly upright and straight combs with many serratures; as little mixture of colour in the plumage as possible; well-feathered legs; small tail in the cock of curly feathers, in the hen of round feathers; large pluff; yellow legs. Any fault in the comb a disqualification.

SQUIRREL (*W. Williamson*).—Squirrels are in confinement mostly fed on any kind of nuts, sopped bread and milk, and most kinds of corn. To tame it let the cage be placed low where persons are constantly moving about, and tempt it by kindness and feeding from the hand. We know of no manual on Squirrel-keeping.—B. P. B.

RABBITS FOR EXHIBITION (*R. J.*).—We have known prizes for weight awarded to Rabbits ten months old, weighing from 9 lbs. to 12½ lbs. A Rabbit at three months old having ears 17½ inches long we consider very likely to be a prizetaker, for they ought to be 21 inches long by the time the Rabbit is ten months old.

LONDON MARKETS.—NOVEMBER 23.

POULTRY.

We have still a good supply of all poultry, and a very moderate trade. Grouse and Partridges are scarce, Pheasants and Hares plentiful.

	s.	d.	s.	d.		s.	d.	s.	d.
Large Fowls	3	0	5	6	Partridges	1	9	2	0

6	SUN	2 SUNDAY IN ADVENT.	47.4	35.9	41.6	21	52 7	50 3	31 2	8 1	25	8 51	340
7	M	Polyanthus flowers again.	47.8	35.9	41.9	19	53 7	50 3	42 3	35 1	26	8 26	341

From observations taken near London during the last thirty-six years, the average day temperature of the week is 47.6°, and its night temperature 35.1°. The greatest heat was 62°, on the 1st, 1857; and the lowest cold, 14°, on the 5th and 6th, 1841. The greatest fall of rain was 0.52 inch.

GARDEN GHOSTS.

WHEN I was in London some weeks ago everybody was talking about the Ghost, and "The Ghost" was upon every bare wall, scaffolding-board, and omnibus. As you went out of Euston Station, at both windows of your cab appeared a Ghost. Your paper was full of Ghosts; and a great heading, "Visit of the Ghosts to the Lord Chancellor," was followed by an account of their visit, and how they behaved, and what his learned Lordship said; but to none of them would he grant the patent—in fact they were only scientific Ghosts, or would-be patent Ghosts.

Now I possess a real Ghost. This is the Ghost of a lady—a very wicked lady, who used to do very wicked things. The front terrace-walk of our house is sometimes called "The Ghost's Walk." I have seen her twice—once while seated at luncheon at one o'clock in the day, and once at night, when I took her for one of the maid servants, and desired her to take some hot water to my room. Several people have also seen her; but I am very anxious to see her again, to ask her a question or two regarding some treasures she knows all about.

"Near the Cell there is a well,
Near the well there is a tree,
Under the tree the treasure be."

So it is said in old verses referring to this house and my Ghost. One peculiarity about my Ghost is that she is only seen about once in four or five years, and then only by those who have eyes capable of seeing more than other people, or who from disposition, temperament, or inclination are on the look-out for something uncommon and novel. My Ghost's name when she was in the flesh was Lady Ferrers, and out of compliment to her I have named a white variegated Geranium of mine "The White Lady." My "White Lady" has scarlet flowers; but I have hopes among my seedlings of finding a good strong-growing variegated one with Madame Vaucher flowers, which I shall call "The Ghost."

But setting aside patent Ghosts, do you not agree with me that this capacity which some people have and some have not, or which they have not at all times, of seeing Ghosts, explains in some degree the sentimental opinions, the theoretical fancies, or, as the owners call them, practical opinions concerning ancient and modern gardening—may not these diverse notions about ancient and modern flower-gardening, herbaceous *versus* bedding plants, be explained by the fact that some of us see Ghosts under certain conditions or circumstances—at all events are on the look-out for them? No doubt my reverend brother in Wiltshire was looking out for a Ghost when he raised "with outstretched walking-cane some little border flower

nestling in its leafy bed." That was keeping the Ghost at a distance at all events. Fancy our florists at a Horticultural Committee meeting turning up a flower with an outstretched walking-cane!

We all of us at times have a Ghost-seeing humour, and that, no doubt, accounts for the change of opinion which comes over us near the beginning of autumn about some of the new bedding plants. There is, for instance, the *Coleus Verschaffelti*. When I saw it in July at the Crystal Palace Mr. Gordon and myself both set it down as a failure, but in September it was quite a different thing. The Ghost had been at it, or I was in a Ghost-seeing humour, for I liked it amazingly, and made up my mind to follow Mr. Earley's advice about it next season. Perhaps after a few years' acclimatising it may become as easy to manage as a variegated Geranium. The same may be said of the *Amaranthus melancholicus ruber*. When I recommended, in the description of the bedding-out at the Crystal Palace, a certain careful treatment of it, I had seen so many failures even by first-rate gardeners, that I was induced to mention Mr. Veitch's mode of managing it. But "W. M. A.'s" account, at page 151, of his easy success makes it at once everybody's plant. Mine, though tolerable in the first part of the summer, became very shabby latterly, the slugs making terrible havoc among its leaves.

In certain quarters there has been as much sensation created by a plant as by the Ghosts. A contemporary gardening periodical recommended the Golden Balm as an edging, in such glowing language, that it was to beat even the Golden Chain, and remain as a permanent ornament; but the writer forgot that plants, like departed ladies and gentlemen, have sometimes a Ghost-like tendency. A certain purchaser, on the strength of the suggestion, bought some plants of a London florist, and golden and beautiful they were when he bought them. But one rather wet day he went to look for his golden beauties—vanished. "Why, they are all green now!" Off he started for the vendor's, and, as I was informed, used by no means Ghost-like language there.

Now that Ghost-caught customer of the said florist leads me to express surprise that no one as yet has seconded your editorial proposal to have an exhibition of bedding plants in 1864. From what I have witnessed this year, the variety of opinions on the merits of plants and the changes of opinion which experience brings about (the *Coleus Verschaffelti* is a case in point, as well as the Golden Balm), an exhibition of bedding plants is as desirable for the nurserymen as for the public. For myself, I hereby record my conviction as an amateur, that such firms as Messrs. Carter, Henderson, Williams, Lee, Veitch, &c., never have and never will recommend anything which they do not believe to be what they describe it; and if I knew nothing about bedding plants, I could go with the utmost confidence to any one of those firms, and I am quite sure they would supply conscientiously what they considered best adapted to my wants: and therefore for any one to suspect our first-class nurserymen of unfair or dishonest attempts to

delude purchasers, is acting like silly timid people, who are afraid of going out after dark for fear of the Ghosts. Still there remains the simple fact that there are silly people in the world, that they constantly suspect the Ghost is near, and that some unknown evil is working against them—in other words, people will suspect nurserymen are too anxious to make money of their plants to care whether their customers are taken in or not; and this fact alone is sufficient proof that an exhibition of bedding plants is most desirable. We do not want more than one or two exhibitions in the course of the season; and these, necessarily, to make them satisfactory, cannot be held till quite the end of June or beginning of July, when the plants to be exhibited have been fully exposed to the air for at least one month, so that their qualifications for bedding-out may be thoroughly tested by open-air exposure. They may be planted in boxes or pots; but the grand test will consist in the constant exposure to all the vicissitudes of the open air for at least four weeks—longer if possible.

I allude to this now, and bring forward the Golden Balm customer as a strong case in point to prove the advantage and protection which an exhibition of bedding plants would be, though I have heard quite as unghostlike language used against other firms, in the hope that during the next few months something may be done to arrange satisfactorily the mode, conditions, and time, for a grand exhibition of bedding plants.

We have lost our leading authority on almost all subjects of open-air gardening, and deeply grieved am I for one. Though personally unknown to me, the late Mr. Beaton's writings have been of the greatest use in diffusing real practical knowledge, provoking inquiry and experiment, and in promoting a higher and purer taste in all that relates to the flower garden. It is impossible, also, to read his articles without being struck with the hearty spirit in which they are written, as if he was in love with the subject, and was only anxious that you should likewise understand and enjoy it just as much as himself. Among nurserymen I believe there is but one universal feeling of regret for his loss, and of grateful remembrance of the benefits he conferred upon gardening. For myself I shall be very glad to contribute towards a monument to be erected as a memorial of him.

But to resume. Your pages are open to judicious suggestions on all subjects connected with horticulture, and I look forward to reading many pleasant articles on open-air flower-gardening even during the frost and snow. May I be allowed, therefore, to express a hope that such firms as I have already alluded to may be induced to offer any suggestions they may think advantageous to make an exhibition of bedding plants really useful to the public as well as the trade? A few attempts have been made even this year. Mr. Holland showed some new colours in Geraniums, and Messrs. Henderson their lovely variegated seedlings; but no encouragement has been given in the form of prizes, still less were the circumstances under which they were grown mentioned—and without the open-air test the public cannot expect to be satisfied of their suitableness for open-air flower-beds.

The only real exhibition, looking at it as a test of suitability, has been afforded by the various public gardens, such as the Royal Horticultural Society's at Kensington, but more especially the Crystal Palace, Victoria Park, and perhaps Kew. The Horticultural Gardens are too near the London smoke to be of use as an experimental garden for flowers; but at the Crystal Palace they generally make use of the round beds between the Rhododendron-beds at each end of the grand terrace for that purpose. These beds make capital exhibition tables, for there the plants are right before the eyes of all the public, and, whether the public has Ghost-seeing eyes or not, there are the plants.

Well, well! we have heard all about the *Coleus* and the *Amaranthus*, but what about the two *Centaureas*? As a bedding plant I do not care for the *gymnocarpa*, but the *candidissima* is a love; the *Coleus* being next to it, and the *Cloth of Gold* round all. This *candidissima* strikes with me just as easily as the *Cineraria maritima*. Do not coddle it too much, and do not be in too great a hurry to get it to root. It makes a magnificent dinner-table plant, or for a flower-stand in front of window-curtains by candlelight it shines

like silver. And then the *Cloth of Gold*. Difficult to get up a stock of it? It does not grow fast, certainly—all the better for an edging; but it will grow fast enough if you give it plenty of rich food. If you want a variegated *Geranium* as a low edging, give it only plain soil; but if you want it to grow rampant and strong it can feed and fatten on the richest; but do not give rich food to plain-leaved *Geraniums*, or you will find them run all to leaf. Then there was, if you remember, *Magenta No. 2* (Beaton's), the flower twice the size of *No. 1*, and such a colour! But there is another coming out to beat even *No. 2*. My choice, however, of the new beauties exhibited at the Crystal Palace this last season falls on Mrs. Whitty (Beaton's), and Lucien Tisserand. Mrs. Whitty is a lovely pink, and as exhibited at Sydenham in that soil decidedly superior to Christine. The foliage is something like the Hybrid Perpetual *Geranium Sidonia*; the flower the same colour as Christine, but more stellate; and seed-pods did not appear to disfigure it, as is the case with Christine. The *Geranium* which took my fancy the most was Lucien Tisserand. It was exhibited in the first round bed at the east end of the grand terrace, and formed an edging to it. It is of the Horse-shoe race, a lovely orange scarlet, the flower round enough to satisfy a florist, and in the Sydenham soil, very dwarf and an abundant bloomer.

It would be a good move on the part of the authorities at the Palace, if they were to offer to place a portion of their ground at the service of the public as an Experimental Garden. Say I want to test a seedling *Geranium*; as soon as I have stock enough for a bed, let it be in my power to bespeak that bed, leaving it when planted to be managed by the gardeners there. This would be an open-air test at once sufficient to satisfy the trade and the public too. This is, in fact, what the late Mr. Beaton did. Nearly all his seedlings were tested at the Crystal Palace or at Kensington. His seedlings, *Crimson Minimum*, a charming dwarf Nose-gay, of rich deep rose colour, not half enough known; Lord Palmerston, *Magenta No. 2*, and Mrs. Whitty were all brought out in that way, and not served out to the public till thus tested.

And, now, if any of your readers happen to be in London, with nothing particular to do for an hour or two, and it is a dull foggy day, let them pay a visit to Messrs. Henderson's nursery at the Wellington Road, and ask to be shown the two span-roofed houses containing the variegated *Geraniums*, and they will see such a sight as will make them forget November, and frost, and snow, and fog. Talk about flowers and florists, why the leaves and leafists will run a neck-and-neck race with them before long. We leafists can produce gold, silver, scarlet, crimson, pink, and magenta all shaded off into each other, or drawn in distinct lines in such lovely combinations as would make poor old Miller beside himself if he appeared again, either under my auspices or Mr. Pepper's, as a Ghost.—F. W. ADEY, *The Cell*.

TRITOMAS.

WHILE the great majority of herbaceous plants, that at one time were extensively grown, have gradually disappeared to make room for the plants considered more suitable for the system of flower gardening which now exists, there are, on the other hand, a very few which the massing and lining of colours have increased in use a thousandfold. Whether this be good or bad taste it is no part of my present purpose to discuss. It will, however, be a happy day for many a hard-driven gardener when a much greater proportion of bedding plants shall consist of such as will be quite hardy or nearly so. Already a gentle tide has set in in this direction, and it is to be hoped that it will swell and gather both strength and beauty till many more really beautiful additions have been made to the present limited show of hardy plants that are available for the parterre. Among the many variegated and other plants recently introduced from Japan there may, perhaps, be a few which some day may be pressed into our service for this purpose.

Tritomas—some of the varieties at least—are among the few hardy plants of this description which have been, and are still, extending into almost every garden with great rapidity. Like all plants which become general favourites,

they are here called and popularised by such names as "Red-hot-pokers," "Volunteers," &c., by those who do not care nor try to remember the frightful names by which gardeners know them. With what sort of a name the "Johnny Bottle" style of man, I will not say gardener, may dignify them it would be hard to divine; although I should not be surprised to hear that it is "Tree-Tuoamers." It seems, however, possible to be "a very good gardener," and at the same time be "grievously ignorant" of I's and my's. There is about Tritomas, particularly to a person who sees them for the first time, something very striking and beautiful when densely marshalled in long straight lines. In this manner they are somewhat extensively grown here as back lines to flower-borders, more especially Tritoma uvaria glaucescens and T. Rooperi. On a line of the former variety, 140 feet long, I counted one day last autumn 857 blooms; and if anything in the form of a line of flowering plants deserves to be described as gorgeous this certainly did, and this variety cannot be too strongly recommended for the purpose.

T. Rooperi is a variety not so well known as it deserves to be, it being of no less merit than T. uvaria from the fact that it is equally beautiful, and has the great merit of commencing to bloom when T. uvaria is past. It continues in flower here nearly the whole winter. While I write (November 18th) it is splendid, and last winter it flowered through frost and snow. It is a much stronger grower than any of the others, and throws up its enormous spikes of flower to the height of 6 and sometimes 7 feet, and sometimes there are smaller heads of bloom lower down from the same main stems. By planting these two varieties alternately in the rows a display of Tritomas can be had for five months in succession.

I should like much to see a long line of T. Rooperi and Gynarium argenteum planted time about, and think the effect would be very striking at this dull season, when outdoor flowers are so scarce. The somewhat stiff and marshal-looking style of the Tritoma with its orange and scarlet flowers would help to heighten the effect of the beautiful plumes of white, drab, grey, and purple of the Gynarium. They would both thrive well in the same soil, as they like good feeding and a good exposure.

It has been affirmed that T. uvaria perpetuates itself true from seed, but such has not been my experience of it. A few years ago I sowed a quantity of seed, and have flowered a great many plants in two long back lines, each 160 feet long, and there are scarcely two plants alike. They differ in habit, and more especially in colour, there being all shades from a pale yellow to a bright scarlet; but very few of them are of equal merit with the original, while only one is considered an improvement on it from its coming into bloom a fortnight earlier, remaining longer in bloom, and having a larger spike of a brighter colour.

Propagation is easily effected by division of the roots, and where numbers are more the object than a few plants that will bloom the following autumn, every eye on the roots will make a plant; but when the object is to obtain a more limited number of plants that will flower in a short time, the plan is to lift the old stools and divide them with as much root to each plant as possible. Where room can be afforded them the best way is to divide in autumn as soon as done flowering, and pot each plant singly into six-inch pots and winter them in a cold pit or frame. In the following April they will have rooted nicely, and should then be planted out in rich deeply-trenched soil, and in autumn each plant will yield one or more blooms according to its strength, and they will form fine flowering stools for the following season. When this cannot be done it is a good way to divide in April and plant where they are to bloom. They are very fond of leaf mould well decayed, and the ground should be well enriched with it. They bloom best if allowed to remain undisturbed for some years, and when they become too thick in the rows they can be thinned out. Of course in time they become immense stools, and unless a border can be devoted to them as immense specimens, lifting and replanting or reducing becomes a matter of necessity to keep them within bounds.

In most localities it is necessary to protect them from severe frosts by putting a little mould or a few half-decayed leaves round their collars the same as is practised with

Globe Artichokes. In our light soil here we draw some of the soil round them with a spade or hoe, and they stand our severest winter with such protection. When grown for back lines the tangled foliage can be trained to grow all to the back simply by being drawn or pushed back in that direction occasionally, and then there is no difficulty in having a row of dwarfier plants close to them where such is required.

Can any one give information as to the merits of T. media and T. pumila? I have not seen them. They are much less, I believe, than the two I have spoken of. T. Burchellii has been discarded as worthless.—D. THOMSON.

POTATOES.

In watching the sailing for some past of the good ship, THE JOURNAL OF HORTICULTURE, a certain instinct as to its handling has caused me to think that any volunteering of mine would be superfluous. So many new and better sailors have appeared on board, that an old hand like myself had better remain ashore making practice, Corporal Trim fashion. But in a letter which I received from the Admiral lately, he there says, "You are not dead, &c. I never saw such a superior show of Potatoes as at a little local show at Daventry. How are they in Oxon?" Now, of course, a hail from the quarter-deck found me willing to push off and pull a rope; and as I have not been idle, I trust that my muscles and tactics may be found up to the mark, and allow me to appear creditably amongst the rigging.

At the Agricultural Show here, a few weeks ago, I overheard this remark—"You should tell your people about you (Santon Harcourt and neighbourhood), to come to the Woodstock Show, and they would meet with competitors worthy of their steel. I do not know where a better assortment of Potatoes can be met with than there." I really think the observation was a just one, and I never saw, with the exception of the Great International Show at South Kensington last year, a better assortment of Potatoes than what we had here this year. I take a little credit to myself for the result, for during a sixteen-years residence I have annually introduced some of the newest and best varieties from all parts of the realm; and although for certain reasons I do not now appear amongst them as an exhibitor, I still continue to introduce new and approved kinds on trial, both for the benefit of ourselves and our neighbours. The following are the results of my practice and observations as regards Potato-culture this year:—

On March the 18th, I planted Daintree's Seedling, Shutford Seedling, Mitchell's Early Albion Kidney, Dalmahoy, Lapstone Kidney. The Daintree's Seedling were well foliaged above ground by April the 26th, and the Mitchell's were peeping up. On the 29th, from the feel of the air and the look of the sky as I was walking down Piccadilly in the evening, my worst fears about them were fully realised. On my return to Woodstock on the 6th of May, they were black. The Shutfords at the latter date were just taking the lead of the Dalmahoy's, the Lapstones having by their tardiness escaped the frosts; but the Daintree's, not to be conquered, sprang forth again, and soon became equally forward to look at with the best of them. I did not attempt to dig the Daintree's this year as a first early, my practice last season having taught me that it was injudicious to do so. I allowed them to remain till after the earliest sorts, and then had, what all must acknowledge to be, an early Potato, which is a good cropper, of good size, and of the very best quality.

On June 2nd, we were using some of the last year's Daintree's, and if I had chosen I could then have begun and continued to dig new Daintree's. On July 23rd, I dug up a root of the latter, which gave twenty-four Potatoes, all of good size except two. They weighed 2½ lbs., and from then till the middle of January, when I anticipate the exhaustion of its store, they have, and will, constitute our preferable sort for cooking.

August 12th, lifted the crop. They were a beautiful sample, not one of them diseased, and they averaged from several careful admeasurements, 28 lbs. per four square yards, which gives within a fraction of 15½ tons per acre.

July 24th, dug a root of Dalmahoy's, which gave twenty-

five Potatoes, and out of them were seven not of fit size for cooking. They weighed 2 lbs. 2 ozs.

August 12th, lifted the crop. A clean, bright sample, and no disease. They averaged 27½ lbs. per four square yards, very nearly the weight of the Daintree's, which they very much resembled, both in top and tuber, but I do not consider them so good a Potato, because when the Daintree's are half cooked, and the water poured away from them, they will finish cooking—viz., steam themselves, and remain firm throughout though mealy. The Dalmahoy's under this treatment retain a "bone in them." They must be boiled till done, which will take ten minutes longer than the former, and then, though an excellent flowery Potato, they are not so good-looking, or of so fine a flavour as Daintree's Seedling. I shall expunge the Dalmahoy's from our garden, otherwise, unless under very careful management, it would become almost an impossibility to recognise them apart, and to keep them distinct. This is how I came by them: Last autumn a late worthy curate paid the rector a visit on his way from Marlborough into Staffordshire. I heard him apologise for the weight of his portmanteau, on account of a good sort of Potato presented to him, and brought in it from the above-named town in Wiltshire. Of course, I was thus placed at once on the alert, and the result was that part of them were exchanged for some Daintree's Seedling, as well as some Shutfords, and Mitchell's, into the bargain, the portmanteau leaving the rectory still heavier than it arrived there.

July 25th, dug up a root of Lapstone Kidney—thirty Potatoes, twenty-two sizeable, and eight too small for cooking. Weighed 3 lbs.

August 12th, lifted the Lapstone, and they averaged 26½ lbs. per four square yards. A clear, beautiful-looking sample, and no disease.

I ought to mention that the Shutford Seedling came in before the Mitchell's Early Albion Kidney this year. I began digging them on June 2nd, and the Mitchell's followed.

SECOND PLANTING.

March 19th, planted the Racehorse, Mitchell's Early Albion, Walnut-leaf Kidney, Ash-leaf Kidney, Early (or Cracked) Shaw, Early Prolific, and one new seedling Fluke-shaped Potato (a cross between the "White-blossomed Kidneys and Wright's Kidneys," sent to me by post especially to try against the Ash-leaf Kidney).

The Racehorse and Mitchell's Early Albion I consider synonymous, and the Walnut-leaf Kidney to be its cousin German, coming in a little later and a little larger along with the Ash-leaf Kidney. I shall give up these varieties for the ridge. In fact, I shall only for the future coddle up a patch or two of the Mitchell's Albion, and the Shutford Seedling, as very early sorts, for the Daintree's Seedling are ready so soon, and are so much more profitable as a crop. The Early Shaws gave a very good yield, which I used in its entirety as a second early from the ground. It is too yellow for my liking. The tops of the Early Prolifics were monstrous this year, and kept green and growing to the last. I lifted them on September 28th, when they averaged 23 lbs. per four square yards. I consider this Potato to be a very good and profitable sort. It is white and good-flavoured, having eyes very deeply set; but the prefix "early" is a misnomer. They all appeared above ground about the same time.

Now for the Seedling, and thereby hangs a tale. It was a perfect-shaped, smooth-eyed, large Potato, and, as I just mentioned, was sent to me by post. In the process of stamping the tuber was split, and four of the most prominent eyes were reduced to a pulp. What Nasmythian powers our post-office friends appear to be possessed of when they become aware of aught destructible in a letter! Owing to this circumstance I am not enabled to report so favourably on the produce of the Seedling as I otherwise should have done. I cut the tuber into four sets, as only four weakly eyes remained to it. This caused me to scrutinise for their appearance many days after the others were above ground, and then they came up unequally. The haulm was distinct, and the foliage something like a dwarf Lapstone. It gave no blossom. It was a month after I dug the others planted at the same time ere I thought it desirable to harvest the seedlings, so I can give no just criterion as to their earliness. The produce was forty-four tubers counted before my friend

Morris at the lifting. He is a judge of the esculent, and he said "it would do." I prophesy that it will become a favourite Potato for a field, and one with which I hope next year to become better acquainted.—UPWARDS AND ONWARDS.
(To be continued.)

HEATING HOUSES ON DIFFERENT LEVELS FROM ONE BOILER.

I HAVE a greenhouse and a vinery, both heated by flues. There is a difference of 5 or 6 feet in the level of the two houses, owing to the steep declivity of the ground, and I want to know if one boiler will heat the two houses without any undue pressure upon it. The most convenient place for the boiler would be at the lower level, and without understanding anything of fixing the hot-water pipes, it appears to me that there will always be a pressure upon the boiler of a column of water of say 6 or 7 feet—i.e., the difference between the highest pipe and the bottom of the boiler. If a tubular boiler be used, would this be too great for the boiler or the cemented joints of the pipe?—A SURFOLK MAN.

[We could advise better if you told us more about the position of the boiler. It would be most conveniently placed on the lower ground just where the ground rises to the higher level. If the boiler there is sunk enough for the top to be lower than the lowest heating-pipe in the low house, and T-flows and returns are used, you can heat the two houses separately, or at the same time, by means of valves. This would be the simplest mode. There will be no danger as respects pressure if the pipes in the upper house were made even higher; but it will be necessary that in the lower-level house there should be an open air-pipe 2 or 3 feet higher than the highest point of the upper-level pipes. If you do not like T-pipes at the boiler you might have a flow and return on each side of the boiler.]

WINTERING BEDDING-OUT PLANTS.

At page 370 appeared a few remarks under the above heading, and bearing my signature. I beg to observe that they were written in March, and formed part of a paper which I intended to send at that time, but somehow or other I failed to do so, and they must have been sent with a later communication. I trust, however, it is not too late to offer a word or two on the above subject, as the notes referred to were not on wintering, but on disposing of bedding plants in the spring, when every available place is filled to overflowing, and the weather is still too cold and uncertain to trust them out of doors without some means of protecting them.

In wintering plants, although it may probably be done in the way described, that plan would involve such an amount of extra work that many would be inclined to give up the attempt before the winter had passed. I have known many instances where quantities of plants have been stored away comfortably, as was supposed, in October, in such makeshift places as stables, summer-houses, spare rooms, closets, cellars, &c., where it was expected that they would sleep away the winter, and prepare themselves for a fresh start in spring; but when spring came a very small remnant, often not more than five per cent. of them, were found to be alive, and those in a blanched and sickly condition. It seems strange, but it is nevertheless true, that there are people who entertain the notion that plants may be stored away for the winter like garden-seats, and such things, that have performed their office for the season. If such were the case it would be a poor speculation for the hundreds of small nurserymen and jobbing gardeners, around large towns, who put up glass structures for the purpose of wintering bedding plants, that they may gain a few shillings by them in the spring. Those who have small gardens and wish to preserve a few plants, not having a pit or greenhouse or any such structure, should not forget that living plants cannot be stored away like pieces of furniture, to be taken down again and used when required. If the plants can neither see, feel, nor speak, still they will not fail to show the result of neglect; and although a very trifling amount of attention

may suffice to keep them alive, to give them none at all will most surely result in their death.

Mr. Fish speaks of taking up Geraniums out of the borders, picking-off the leaves, and packing them together in boxes, pots, &c., or in a cold pit, expecting to keep them for use another season; but these will have such attention as is necessary, and by planting-out time next year they will doubtless be healthy plants. This, however, is recommended as a resource when the supply of plants from cuttings is too limited. Those who have opportunities of taking sufficient cuttings in July or August will have no occasion to preserve the old plants, and though a pang of regret may be felt at the idea of consigning a lot of plants to the rubbish-heap, still it is in most instances merely doing now what will have to be done in the course of the winter.

I have kept large quantities of plants in various makeshift ways, and with an amount of trouble and labour that nothing but a decided interest in the matter could induce one to undertake voluntarily. Sometimes my efforts have been followed with the much-wished-for success, and not unfrequently with grievous disappointment after taking and striking cuttings by the thousand in July and August, filling cold pits and frames with them in November, and then having to throw great numbers of them away in March. I have tried the practice of taking up Geraniums out of the beds, and storing them away in a cellar; but I cannot say that the result has been at all satisfactory. Others, however, may have been more successful, and I by no means dispute the possibility of doing so successfully.

Those who can winter their bedding stock in suitable glass structures will have no difficulty to contend with greater than the want of space. But where it has to be done in unheated structures the difficulty, as is well known to those who have made the attempt, will be very much increased, not only on account of more time being required, but because there will be two great enemies to contend with, where, in a heated structure, there will be only one. Frost must be kept out by shutting and covering up, but doing so at the same time encourages damp and mildew, which are only dissipated by opening and uncovering, so that two forces are exerted in opposite directions. It will be seen, then, what constant attention is necessary. I have come to the conclusion that the best of all unheated structures for wintering plants are common wooden frames, such as are used round London. These are about 20 inches high at back, 12 in front, 6 feet from back to front, and the lights about 3 feet 6 inches wide. These frames are made of one, two, or three lights each, the lights being easily managed. In these I would place 6 inches thick of sifted coal ashes, this material, in my opinion, making the best flooring to stand the pots upon; and round the outside I would bank-up at least a foot of rotten dung, earth of any sort that will hold together, or any kind of stuff that will make a good thick barrier to keep out frost. This, I consider, affords greater resistance to severe frosts than a nine-inch brick wall; four-inch or four-and-a-half-inch walls will want increasing in thickness in the same manner, and if built shallow, probably answer as well as frames, only they have not the portability of the latter. I have generally used manure to bank round the frames, as it is a good plan of helping to rot and air the manure for potting purposes, while it is usefully applied. In frames prepared in this manner bedding stock can be wintered with as little trouble as can be expected in unheated structures, and there is no fear of exciting the plants into growth before that may be done with safety, which is seldom earlier than April.

I have often found that where gardeners have practised wintering their bedding stock in frames, they keep the covering on the glass so long as frost continues; then when the covering is removed the plants are found in a half-rotting condition. Now, this practice is the most difficult to understand, and yet it is the one most likely to concern the safety of the plants. I have wintered Geraniums, Verbenas, and such bedding stock in wooden frames and brick pits without any auxiliary heat, and always made a practice of pulling the litter off daily, even in the midst of frost and snow, and found that the advantage of doing so more than counterbalanced the danger of the plants being frosted; in fact, it is well known that a few degrees of frost will not hurt such plants if they are dry, when the same amount of

frost will injure them considerably when they are damp. If the frost reaches the plants when they have been closely covered for any length of time, the chances are that it will make sad havoc amongst them. This, of course, then, is the real gist of the matter. It is all very well to tell any person inexperienced in such matters that if he only possesses a garden-frame he can certainly winter a few plants in it; but this is only telling part of the story; a constant and daily attention is necessary, and more depends on the care and tact of the manager than on the frames.

If these notes are found useful it will be chiefly among the owners of small suburban gardens, to whom it yearly becomes a serious consideration as to how they are to prevent the apparent waste and loss of their bedding plants. I fancy it would amuse some of our gardening friends to hear of some of the shifts which I have seen adopted in such cases, and almost always with a like result—that is, the loss of the plants some time or other during the winter, and this, in nearly every case, because the plans adopted were based simply on the wishes or convenience of the owner without regard to the nature or wants of the plants.

The term "wintering plants" conveys something more than merely keeping them beyond the reach of frost. What I have said with regard to doing so in pits and frames applies to struck cuttings, to plants established in pots, and to plants taken up out of the ground and potted in September or early in October. But it will be seen that Mr. Fish talks of taking up plants even as late as November, picking off the leaves, and packing them together in pots or boxes, or on the bottom of a cold pit; but the experienced gardener, whose daily and yearly practice it is to attend to such matters, is in a very different position with regard to the treatment of plants as compared with the amateur, who handles only a few dozen plants in the course of the year, and those only during an hour of relaxation from more serious and important business. In the latter case the constant and daily attention to frames and pits is scarcely desirable, to say nothing of the work attached to them being none of the cleanest. It follows, then, that a better and cleaner method of wintering plants is greatly to be desired; and happily it is within the reach of everybody, and is pretty well known; it is to keep them in windows. I should be very sorry to deceive people by simply repeating the various ways and means of keeping plants that have found their way into print, and which are eagerly caught at by small growers, and put into practice as far as is possible with a certainty of failure. Common sense must tell any one that living plants are not to be buried in the earth or hung up in the air by their roots for seven months of the year, and then to be put in the ground to grow and flourish to the great delight of the cultivator. There must be forethought and a little work; those, however, who really have a partiality for flowers will accept these conditions as a matter of course; but then there are many who profess to have a partiality for flowers whose true motive in having them is merely because it is customary, who complain of the trouble they give, and eagerly seize any makeshift plan of disposing of them, which promises to preserve them and dispense with the trouble of constant watching, which the more rational course entails.

After all that has been said, those who do not possess a greenhouse or other heated structure will find the best and cleanest method of keeping a few plants is to keep them in their windows. Follow the advice of Mr. D. Thomson: Take some six or eight-inch pots, drain them, and fill with good porous soil; take good strong cuttings in July, remove the lower leaves, and insert as thickly as convenient round the pot; place them in the full sun if Geraniums; if Verbenas, Cupheas, Tropæolums, or other such bedding plants, place in the shade, and cover with a hand or bell-glass; if Calceolarias, wait till October and act in the same manner. Leave all out in the open air as late as can be done with safety; then remove them to the window where they can be placed on shelves, which can be supported by placing strong hooks in the window-frame, and slinging the shelves on wire or blind-cord. There the young plants should be watched, and kept as nearly dry all the winter as can be done without allowing them to shrivel up. Earlier in the season Mr. Thomson gave some directions for striking cuttings which it is scarcely necessary to repeat, but, as he truly says, six

or eight-inch pots are better than smaller ones, as the plants do not so quickly dry up, and preserve a more regular moisture, and I believe more plants may be kept in a given space than by using smaller pots.

Even those who possess a frame or small unheated pit will find the advantage of keeping their plants in windows, since, besides having them drier and more under the eye, they may sow a crop of Radishes in the frame or pit, and when these are used-up they can pot-off the bedding plants and place them in the frame. It will be found that the contents of a few of these store-pots when potted-off will fill a two-light frame, and if properly attended to in watering, &c., sturdy plants will be secured for planting out after the middle of May.—F. CHITTY.

CLOSE-PRUNING VINES—DAMPERS.

In your Journal for the 18th of November, 1862, you kindly answered my question on the close-pruning of my Vines. I will now give you the result, and have further to trespass on your kindness for an answer to my present inquiry.

I started my Vines as recommended, or rather I should say they went away without me in the end of February, the weather being very mild.

The Sweetwater had three old rods. Two of these broke so very irregularly, that I had to bring a young cane from the bottom and cut these away. The third rod had a few bunches of Grapes, so was allowed to remain, though very scant of shoots.

The Black Hamburgs had five rods, two of them, only, two or three years old. The three older rods had to be treated in the same way as the Sweetwater, for they broke in patches and bore no fruit. So these rods were cut away, and a very vigorous young cane brought up from the bottom with leaves at least 1 foot in diameter. The other two rods gave me fourteen or sixteen bunches between them.

The Muscadine, which had for two years been very shy, broke at every joint, and had two or three bunches almost on every shoot. The foliage and fruit were very small to what they formerly had been.

The Golden Hamburgh broke pretty well; but did not fruit nearly so well, nor were the bunches so fine as in the year before.

The Black Champion next to it, first time of fruiting, had eight enormous bunches, which were the admiration and envy of all my gardening friends.

After reading your answer last November, having plenty of room between the Vines, I planted a Bowood Muscat at the warmest end of the house, a Lady Downes', and two Black Hamburgs, in order to gain a year should these old Vines have to come away. I shall, however, have to cut away one Black Hamburgh next the Muscadine, seeing it did somewhat better than usual; but will you tell me if I am to close-prune these Vines again this season or leave a short spur 1 inch long with two buds as I used to do? The wood seems well ripened.—T. B. T.

P.S.—In your last week's Number you gave some important information respecting the use of dampers to flues. Do these remarks apply to the use of a damper with a saddle boiler or only to flues?

[There is no doubt that you have carried the close-pruning or spurring system to an extreme, and have cut away every bud from which fruit could be expected, leaving nothing but latent or imperfectly developed buds, and hence the irregular crop which your Vines have borne. The Royal Muscadine, which is a very free fruiter under any system of pruning, and generally makes a more numerous cluster of eyes at the base of the spurs, has, therefore, stood the severity to which you have carried this system of pruning in this case. From the success of the young rod of the Champion, and what you say of the Vines generally in former years, we cannot suggest any other cause of your failure. The close system of pruning, like every other, can be carried to excess, and had you followed a course between that which has caused your failure and your previous system you would have no doubt secured a crop. We always leave the bud at the base of last season's growth, and in very few cases do we ever prune closer, and such is generally termed the close system. When the Vines are well ripened there is no fear

of a failure, and the bunches, though shorter than when an eye or two more are left, are generally much more compact and serviceable, and the berries are larger.

In pruning this season you cannot err, if your Vines are well ripened, in pruning back to the bud at the bottom of the growth, and from which a leaf has been formed. There is no teacher so thorough as experience; and if you are afraid to cut back to one bud leave two, as you used to do, on every other spur, and you will have the thing exemplified before your own eyes, and there will then be no anxiety about a crop if all else is right. Whatever arrangement you carry out about leaving your young and old Vines, do not overcrowd your Vines. They should not be closer than 2½ feet at least.

A damper is a very necessary appendage to a boiler. By it the heat can be confined about the boiler, where alone it is wanted. In the case of a flue, if a damper is used at all it should be at the furthest point from the furnace, whereas with a boiler and no flue it should be immediately above the boiler, in order in both cases to retain the heat where its force is wanted.—D. THOMSON.]

CULTURE OF SPECIMEN MIGNONETTE.

RESEDA ODORATA or Mignonette is an evergreen under-shrub, perishing annually, as far as its bloom-stems are concerned, in its native country, Egypt. It was introduced into France in 1740, and was brought from the Royal Garden at Paris to Windsor by Lord Buteauan, in 1742. Don, however, and London give 1752 as the date of its introduction. There is a prevalent opinion that there are two varieties, the one an annual, and the other a shrubby variety known as the tree Mignonette. In the "Botanical Magazine," t. 29, *Reseda odorata* is described as an annual, and in the "Botanical Register," t. 227, mention is made of a *Reseda odorata frutescens*, or frutescent Mignonette, which is said to grow 2 feet high. I mention this circumstance in order to show that it is possible that there may have been an annual variety in addition to the one we now possess. Mignonette, or "Little Darling" of the French, is much cultivated on account of its fragrance, and it is rather remarkable that such a "fragrant weed" (for its beauty is to me unseen), should remain so long unimproved. Beyond a solitary variety it remains in the same unimproved condition as when first introduced; and although it may not be possible to make it more ornamental, it certainly is worth an effort to strive to obtain a hardy variety. There are more than two dozen species, some of which would, no doubt, readily yield to the hybridiser's pencil. Of those most likely to afford the best results seem to be *Reseda frutescens*, a small shrubby species from Spain, and a rather taller variety from the same country, *R. bipinnata*. I have made several unsuccessful attempts to get the pollen of *R. odorata* to take on the British species, *R. hutea* and some others, but only in one instance did the pollen take effect, and the plants raised were more tender than the parent, *R. myriophylla*. Who will be the first to obtain a hardy sweet-scented perennial Mignonette? Growing plants of Mignonette for in-door decoration is somewhat difficult of attainment, though by no means so difficult as is generally imagined. There are several methods of growing tree Mignonette, but I shall only describe one, and that is as simple as it is satisfactory in its results. Early in June select as many plants from the out-door sowing as are wanted, making choice of those that are stiff, strong, and promise a vigorous growth. Take them up with balls, and place singly in 48-pots. The plants should not be less than 2 and not more than 3 inches in height. The compost best suited for potting at the early stages of the plant's development, is light loam and leaf mould in equal parts, with a free admixture of silver sand. The plants, or rather the pots containing them, should be plunged in coal ashes in a light and well-ventilated situation, but shaded from the sun from 10 o'clock in the morning until 4 in the afternoon, and this is the position they should occupy until the beginning of October. After potting the plants must be gently watered and shaded with mats for a few days until they become established. Water must be given in dry weather, and once or twice a-week they should be watered with liquid manure much diluted with rain water.

By the middle of July the plants will be growing vigorously, when, if the pots are full of roots, they must be potted into 32-sized pots in the same compost as before. A gentle bedewing of the plants overhead after hot dry days will much refresh the foliage, and watering being duly attended to they will make rapid progress. When the leader shows for bloom put in a stick in the centre, which should be about 2 feet long, a trifle less than the thickness of the little finger, and painted green. Pinch off the bloom on the leader on its first appearance, which will cause the side shoots to grow strongly, the blooms on them being pinched out as they appear. This pinching is to be continued throughout the summer until further notice. Take care that the plants do not root through the pot, it being a good practice to lift them frequently to see that they do not. Tie the leader to the stake, and peg down the side shoots so as to feather the plants to the pot.

In August pot them into 24 sized pots, using a compost of light turfy loam half, the remainder leaf mould or peat and cowdung two years old in equal parts, adding a liberal sprinkling of silver sand. The drainage should occupy about one-third the depth of the pot, and must be made perfect. A little sphagnum or cocoa-nut fibre placed over the crocks will prevent the drainage becoming choked. They will require but little water, but they must not be allowed to suffer from the want of it. When they really need watering give them enough to reach the drainage.

Early in October they should be potted into their blooming pots, 9 inches in diameter, which are large enough for ordinary purposes. The drainage must be well attended to, and the neck of the plant kept somewhat high. After potting they should be placed in a cool, dry, light, well-ventilated greenhouse, and as near the glass as possible. They will require but little water, and yet the foliage must not be allowed to turn yellow from the want of it.

Provided the plants have been duly pinched—i.e., the flowers nipped off—and the shoots regulated so as to form an even-shaped plant feathered to the pot, and tapering upwards, they will be fully 20 inches in diameter, and from 18 inches to 2 feet in height by the middle of December, after which time the flowers should not be pinched off, but allowed to bloom. No water must be given so long as the soil contains enough moisture to maintain the plant without flagging, and then water must be given freely; for a little to-day and a drop to-morrow is slow poison. Very weak liquid manure may be given at every alternate watering, but it should be heated to a few degrees over rather than a few below the temperature of the house in which the plant is growing. The plants will bloom finely through the winter, and are the delight of the ladies. Care must be taken to cut out all spikes done blooming, as they weaken the plant, and are unsightly. The plants will continue in good bloom until June, when they may be cut back a little, some soil being taken out of the pots, and its place supplied with fresh compost. The plants will grow freely and bloom continuously through the summer in a cold, light, well-aired greenhouse or conservatory, and on through the autumn and winter; but the blooms they afford are not equal to those from younger plants either in fragrance or size. It is advisable to raise fresh plants annually, retaining the old until such time as the young commence flowering. By this plan Mignonette can be had every day in the year.

In conclusion, I would make a few general remarks. Mignonette, when subjected to artificial treatment is impatient of damp, particularly in its early stages, but this is obviated by keeping the plants outside, for it is not uncommon not to sow the seed until the beginning of August, which injures the young plants to the fatal moisture of the autumn months. Watering overhead is a dangerous but indispensable process, and should only be practised on bright sunny mornings, and then it should be given through a fine syringe. The shoots are so easily parted from the stem that syringing should not be so copious as to cover the foliage with water and render it unable to carry the weight, or the shoots are sure to slit or become detached from the stem. Better not to syringe at all as do this, for nothing makes a specimen look uglier. The plant is also extremely susceptible of variations of temperature, extremes of heat and cold being positively injurious to its well-being. The temperature should, therefore, be kept steady, and ranging

near 45°, never lower than 40° or higher than 50° except on rare occasions. Too much air and light cannot be given nor too much sun during winter. Another essential is that the plants be kept near the glass, so as to prevent drawing, and to give them all the strength possible. These points attended to, the plants will grow with a vigour equal to the wishes of the most sanguine cultivator or admirer.

Lastly, allow me to protest against the practice of tying every shoot to a stake. Some people imagine or have a fancy that every shoot requires a stake, and one it must have. Nothing, however, looks so unnatural. Symmetry can be had without stakes; and if a plant cannot stand on its own legs it is grossly maltreated by being tied and made to assume a figure at once unnatural, extremely disagreeable to refined taste, and altogether unlike assisting Nature. It is deforming her, and generally meets with the disappointment that violations of Nature's laws so justly merit.—GEORGE ABBEY.

[The above is written to meet the wishes of "J. J. J." her query at the time being replied to briefly.]

BURYING DEEPLY THE ROOTS OF ROSES.

HAVING made a Moss Rose-bed last spring, and being now desirous of raising it 9 or 10 inches, I wish to know if putting earth up the stems of the Roses to that height will injure them. I do not wish to take up the Roses again, fearing it might spoil their flowering.—A. M. A.

[To earth-up the stems of your Roses to such a height would be decidedly injurious. If the Roses are in good condition they will bloom next year if carefully lifted and replanted, which is the only way that will admit of the soil being raised so high without being injurious. If the roots are carefully disentangled from the soil, and as few of them broken as possible, at the same time preserving a ball of earth at the stem if it can be done, and if planted immediately, there is no fear of their not flowering.]

GARDENERS' NAMES FOR FLOWERS.

MY only reason for taking up this subject was simply to condemn those who, having themselves secured the advantage of a liberal education, are inclined to sneer at the shortcomings of others, who, without any fault of their own, have in this respect been less fortunate.

Gardeners are themselves very frequently the sons of gardeners, and the employers of gardeners must know full well that their gardeners are, generally speaking, seldom in a position to give their sons an expensive education, however anxious they may be to do so: consequently classically educated gardeners are not to be expected. Still, by dint of patience and perseverance, assisted by the numerous works on horticultural subjects which are almost daily issuing from the press, including accentuated catalogues of plants, &c., many gardeners do and nearly all may attain to something approaching a correct pronunciation of the names of flowers.

I admit that, on hastily perusing the first letter of your reverend correspondent, the "WILTSHIRE RECTOR," on this subject, I felt inclined to say with young Norval—

"That there are men
Who borrow friendship's tongue to speak
Their scorn," &c.

But I am now quite ready to admit that I have judged your correspondent wrongfully; and if my former communication to you on the subject contained anything offensive to him I sincerely regret it, and from the conciliatory and kind tone of his last letter I feel quite sure that he has freely forgiven it. I have no hesitation in fully agreeing with him that it is much better to endeavour to raise the men to the correct standard than to sink the standard to the men. And I sincerely trust that the kindly advice of your reverend correspondent may be instrumental in stimulating young gardeners, at least to endeavour to attain a correct pronunciation of the names of the plants which many of them succeed in cultivating so well.—G.

MISTLETOE ON THE GOOSEBERRY.—I saw in a garden near Maidstone, Kent, Mistletoe growing on the Gooseberry

bushes, which were very old, and of large size. The Mistletoe was very strong. I did not notice it on any other tree or bush except the Apple.—KATE.

VARIEGATED ARABIS.

A PLANT of this miniature gem came into my possession last spring with the name of *A. lucida variegata*. Whether this is the original kind or not I am not in a position to say; but for the satisfaction of your correspondents I have no hesitation in asserting that this identical kind is deeply margined with pure yellow—not a dirty white—and is, without doubt, a most valuable addition to the class of dwarf variegated edging plants. It will prove a great acquisition to the amateur, for it is quite hardy, is readily increased from side-shoots or offsets, and grows freely in any good garden soil. Slugs are its greatest enemy, and it requires careful watching in winter to prevent these pests from riddling its delicate leaves. Grown as a dwarf miniature pot-plant, it looks exceedingly pretty for a flower-stand or small vase.—JOHN EDLINGTON, *Crom Castle*.

TODMORDEN BOTANICAL SOCIETY.

A MEETING was held on the 2nd ult. Many specimens lay on the table: among the more notable were monster examples of the curious *Polyporus betulinus*, gathered from Birch trees in the neighbourhood. This may be regarded as a semi-commercial fungus, being employed, at times, in the manufacture of razor-strops. It is highly interesting, as, indeed, are most of the fungi. The fungus family, moreover, is a useful one, very many species, although not regarded here as edible, being the prized esculents of other countries.

A communication was read from Mr. J. Holt, the Secretary of the Prestwich and Pilkington Botanical Society, announcing for sale the renowned "Shepherd Herbarium," comprising 160 vols. (folio) of dried specimens of plants. The Secretary was instructed at once to communicate with Mr. Holt, with a view to ascertain whether the herbarium can be forwarded to Todmorden for inspection by the members, and, in case of a difficulty in this, a number of gentlemen were appointed a committee or deputation to go and inspect on the Society's behalf.

Mr. J. Lord, Bridge-end, Todmorden, presented to the Society one hundred and fifty sheets and thirty packets of dried specimens of British mosses by name, being the whole of the bryological collection of the late Mr. Edmund Holt, senior.

Edmund Holt died some twenty years ago. He was well known throughout the Todmorden and neighbouring valleys as an enthusiastic botanist and naturalist, and a man of strong individuality withal. His shrewdness and sagacity were uncommon, and his "sayings" are still quoted in the neighbourhood as oracular, and that not seldom. "As old Ned Holt used to say," is the phrase. Who hasn't heard it a hundred times? Whilst alive, "old Ned Holt" must have been a power, influencing by no means a narrow circle, and now that he has been twenty years dead, his words (or "sayings") are a power still. He was commonly pronounced an "oddy"—a "curiosity." But why was he odd?—why was he singular? Because at every step he took over this earth Holt found "the Beautiful," "the Wonderful," and admired and wondered accordingly (perhaps somewhat demonstratively), whilst the purblind people about him saw "little or nothing to admire or wonder at." The glorious sun shining in the heavens and casting its wealth of colours over the clouds and over the earth, was no miserable "farthing candle" to this man. "The Primrose by the river's brim" was more than a yellow Primrose to him, and therefore did the Peter Bells amid whom he lived and moved regard him as a "curiosity"—an "oddy." Such men—men whose hearts and minds are opened to the beauty of the universe—are too much of "enriositytes" and "oddiyities" even now. "Heaven lies about us," if we did but know it—Holt knew it. If we do but open our eyes we walk in Paradise—Holt opened his eyes, and therefore he was "odd." Holt's heart was tender in the extreme, as is the heart of every true lover of Nature and of God. He was not unfrequently overheard

apostrophising in (supposed) solitude his favourite flowers as he botanised along our hill-sides through the changing seasons in all weathers. The beautiful flowers were friends of his, and their blue eyes were as dear to him, and almost as sentient, as the blue eyes of his human friends. However much hollowiness or falsity there might be in the world's blandishments, with the flowers, at least, he could hold pure converse. It was a holy fountain this, at which he could refresh and fortify his soul when wearied by the narrow cares and crosses of life. Each of us can do the like! Thousands of miles did this man wander whilst searching for the humble Mosses and Lichens, which to common unobservant eyes are invisible, or, if seen, are passed carelessly by.

"Oh, many are the poets that are sown
By Nature—men endowed with highest gifts—
The vision and the faculty divine,
Yet wanting the accomplishment of verse."

CHICORY: ITS USES AND CULTURE.

OTHER readers of your Journal besides "J. S." will probably be interested by an account of the plant which now constitutes one-half of what is termed "coffee." I therefore submit the following:—

Chicory or Succory (*Cichorium intibus*), is an indigenous fusiform or taprooted perennial, abounding in some parts of the country, but of local rather than general distribution. The leaves are strap-shaped, about 3 inches wide and a foot in length, not unlike Dandelion (*Leontodon taraxacum*), to which it is closely allied. The flowers are produced on long spikes, branching and tapering upwards, which give the plant a pyramidal habit and elegant appearance. They are of a bright and lovely blue colour, each the size of a crown-piece, and are produced profusely from June to September. In a wild state, the flower-stems do not attain more than from 2 to 3 feet in height, but under cultivation they grow to 6 or 8 feet; and in the herbaceous border not one of the vaunted beauties of the flower garden is more ornamental in its season. The roots are large, succulent, and elongated, not unlike white Carrots, but having a multiplicity of fibres adhering to them like Salsafy.

The leaves when blanched are an excellent substitute for Endive, and are, therefore, used as a salad. In addition to their use as a salad, they afford a great bulk of herbage, which is considered good food for cattle. The roots form the Chicory of commerce.

1st, AS A SALAD.—For this purpose the seed is sown about the middle of May, in drills a foot apart. The ground is frequently hoed between the drills, and the plants are thinned out to 6 inches apart. Beyond hoeing between the rows and keeping clear of weeds, the plants need no further attention until November, when the roots are taken up and stored away in a cool place, so that they may be at hand for forcing. The tops are cut off about an inch above the crown; for these roots, unlike those intended for roasting, are wanted to grow. If a dark and rather warm cellar is at command, the roots may be placed there in moist soil with the crown above the surface. A temperature of 50° is quite high enough; for if brought on too fast the leaves are very narrow, or little better than the midribs of white Beet—in fact, they cannot be forced too slowly; but still the quicker they are forced the less bitter is the salad. It looks better when the leaves are broad, and these should be cut when about 6 inches in length, in which state they make an excellent substitute for Endive, but, like substitutes in general, not half so good as the genuine article. When a cellar is not at hand I have put about a dozen roots in a 12-inch pot, and after thoroughly moistening the soil placed it under the shelves or tables of any house with a temperature above 50°, but not exceeding 65°, and then inverted a similar-sized pot over it, closing the holes and other openings with clay. One of these pots will afford a good-sized daily salad, and sufficient pots should be introduced at weekly intervals to meet the demands of a family. Pots, however, not being always at hand, I have hunted up a narrow box, and knocked one end off, nailing on the loose side, and then bored holes all round about an inch in diameter, and about the same distance apart. Commencing at the bottom, lay about an inch of well-moistened soil just level with the first tier of holes, and then place the roots with their crowns just

peeping through the holes; add soil, pressing it firm, then more roots, and so on to the top, when we have a hundred roots which will afford twelve good salads. The box may then have the end nailed on, and be placed on end in a Mushroom-house, or some such dark and warm place. Three such boxes are enough for a good-sized family, introducing one ten days after the other, and refilling or otherwise as circumstances may require.

2ND, AS HERBAGE FOR CATTLE.—My opinion of this is that cattle are not so fond of it as to "devour it greedily," which is what some say they do. I, however, have seen many acres of Chicory, and find that cattle eat everything in the field in preference to it. They leave it the last because they do not savour it. Let new-fangled farmers say what they will, nothing is better than grass and some firm sweet Mangolds and Swede Turnips for feeding cattle.

The seed for this purpose is sown in the beginning of April in drills about 9 inches apart, and is hoed and thinned to 6 inches apart in the rows. By July the plants are strong, and as this happens to be the time when pastures are becoming bare, the cattle are turned into it. Some of the plants will run to seed, and to these the cattle are more partial than the leaves. Chicory affords a supply of herbage until late in the season.

3RD, ITS ROOTS AS COFFEE.—The soil should be rich, friable, sandy, and deep. It should be dug or ploughed deeply in the previous autumn, and laid up rather rough, so that the frost may pulverise it. If the soil is poor it should be heavily manured in autumn, prior to its being turned up for the winter. The land is better when in good heart to begin with, for newly-manured land is apt to cause the plants to run too much to top without giving a corresponding amount of root. The ground should be cross-ploughed in the spring, dragged or heavy-harrowed, doing it in dry weather. Couch and other noxious weeds should be thoroughly eradicated before an attempt is made at growing this crop; and the ground should be naturally, or be made, something like flour by the second week in May. The soil cannot be too fine nor too rich for Chicory, as long, thick, straight roots are the object aimed at. The field having a fine powdery surface by the second week in May, the seed is then sown on the level with an implement known as the "Chicory-drill," which deposits the seed in rows 12 inches apart, about half an inch deep, and a like distance from seed to seed. A wooden roller is mostly attached to the drill, behind the coulters, which closes the drills after the seed is distributed. In case of there being no roller attached to the drill, a light wooden roller is passed over the sown part before the drills become dry, so that there may be no seed lying dormant until rain falls. The seed should be new, for plants from old seed are more apt to run to seed than new. Five pounds of seed are usually sown per acre.

Chicory land is mostly very prolific in annual weeds—as Chickweed, Groundsel, &c.: therefore the hoe should be plied between the rows immediately the plants indicate where the rows are. When the plants are fairly in rough leaf they should be thinned to a distance of 6 inches apart, taking away the weakest and leaving only the strongest. In thinning it is a good plan to strike the drills crosswise with a hoe 5 inches wide (also termed a Chicory-hoe, for this plant, being a special crop, has tools especially set apart for its cultivation from beginning to end), taking two rows at once, a boy or woman following the striker to single out the plants. In a short time after the singling-out the whole will require hoeing again, and the rows to be run over to make sure of the plants standing singly or at the proper distance apart. After this the hoes are plied to keep down weeds and benefit the plant by frequently stirring the surface. Weeds must not under any circumstances be allowed to get ahead, nor the surface to become baked and hard, for this would render the produce inferior in size and quality. This crop cannot be too highly cultivated, nor can the soil be hoed too often until the plants attain the size when hoeing would injure the crop by breaking the leaves.

After discontinuing hoeing, the plants need no further attention until November, when the roots have to be taken up. This operation is effected by means of a Chicory-spade which is handled like another spade, so far as the shaft and hilt are concerned; but the digging part is only about 2 inches wide and 1 inch in thickness, and is thinner towards

the bottom. This implement* is about 1 foot 6 inches in length of blade, and a shoulder is put on the shaft on which the foot is placed in thrusting it into the soil. This instrument is thrust down by the side of the Chicory plant as near to it and as perpendicularly as possible. The operator then commences "prising," or weighing down with the right or left hand, whichever he happens to have on the hilt of the spade, and thus cuts or breaks the root a good depth below the surface, and having the top in his other hand the root is drawn up and laid on the surface. He does this in half a minute. After him follow women or boys, who cut the tops off quite close, and throwing the roots into rows they are put into carts and taken to be washed. A running stream is best for this purpose. A sort of crate made of laths is used. It is 6 feet long and 3 feet wide, the laths being nailed so that half-inch interstices or openings are between them. The crate is open at the top. It is fixed with four stakes so as to be clear of the bottom of the stream, that dirt may pass away, and into it the Chicory is put. With a short-headed wooden rake with very long teeth the Chicory is moved to and fro until white and clean, when it is put into carts as clean as the Chicory itself, and conveyed to the kiln to be prepared for the grocer. Care must be taken to well wash the Chicory, and to cut the tops quite close, or the Chicory-drier will cavil about it, probably reject it owing to its not being delivered according to bargain, or take so much per ton off for the dirt on the roots and the waste of the top, which must be done before it is dried, for Chicory is gritty enough without dirt. The roots are then cut transversely into slices and dried in a kiln; but I omit the process, as no written directions would avail "J. S." without plans and details which I am not provided with. Personal inspection and practice are necessary to the proper drying of Chicory, and a kiln is hardly necessary for one grower. The usual plan is to sell the raw produce to the owner of a kiln, as a kiln will dry the produce of several growers.

After Chicory is dried it is sold to the Chicory-roaster, by whom it is submitted to the action of heat in closed iron cylinders similar to coffee, and after roasting the slices are broken into what are called "nibs." The roaster not unfrequently uses a small portion of fatty matter, as lard, in the course of the process, and, finally, though not always, dusts the "nibs" over with some red colouring matter, as Venetian red, to impart brilliancy of colour.

The produce of an acre of Chicory is from four to five and even six tons, and the roots were formerly worth from £8 10s. to £10 10s. per ton; but now I am informed by Chicory-growers, that it is not worth growing, as it impoverishes the land, and does not pay so well as other agricultural produce. For these reasons they have given up growing it. Where once there were an hundred acres of Chicory in a township, now there are none but the roots that have escaped from cultivation.

Analysis shows that Chicory contains none of the active principles of the three non-alcoholic beverages—tea, coffee, and cocoa. It contains none of their refreshing and invigorating properties, having neither thein, nor caffeine, the respective active principles of tea and coffee: therefore, it is very questionable indeed whether an infusion of Chicory roots is of any value as a beverage. It certainly is no substitute for coffee, but it is said to be an aperient, and at other times acts as a diuretic. Taken along with coffee in the proportion of 35 per cent., it is said to produce a sense of weight at the stomach, causes languor and headache, and has been assigned as one of the exciting causes of amaurosis. It contains no essential oil, therefore, has not the fragrance of coffee. Dandelion roots make as good coffee as Chicory, and are a better medicine, though neither of them ought to be taken as an article of diet, yet popular taste seems as if it ran after the most nauseating draughts.—GEORGE ABBEY.

GERANIUM LEAVES FOR CUTS.—The leaves of Geraniums are an excellent application for cuts, where the skin is rubbed off, and other wounds of that kind. One or two leaves must be bruised, and applied on linen to the part, and the wound will become cicatrised in a very short time.—MISS FRY.

* It is the best of all implements for eradicating Docks in meadows or pastures.

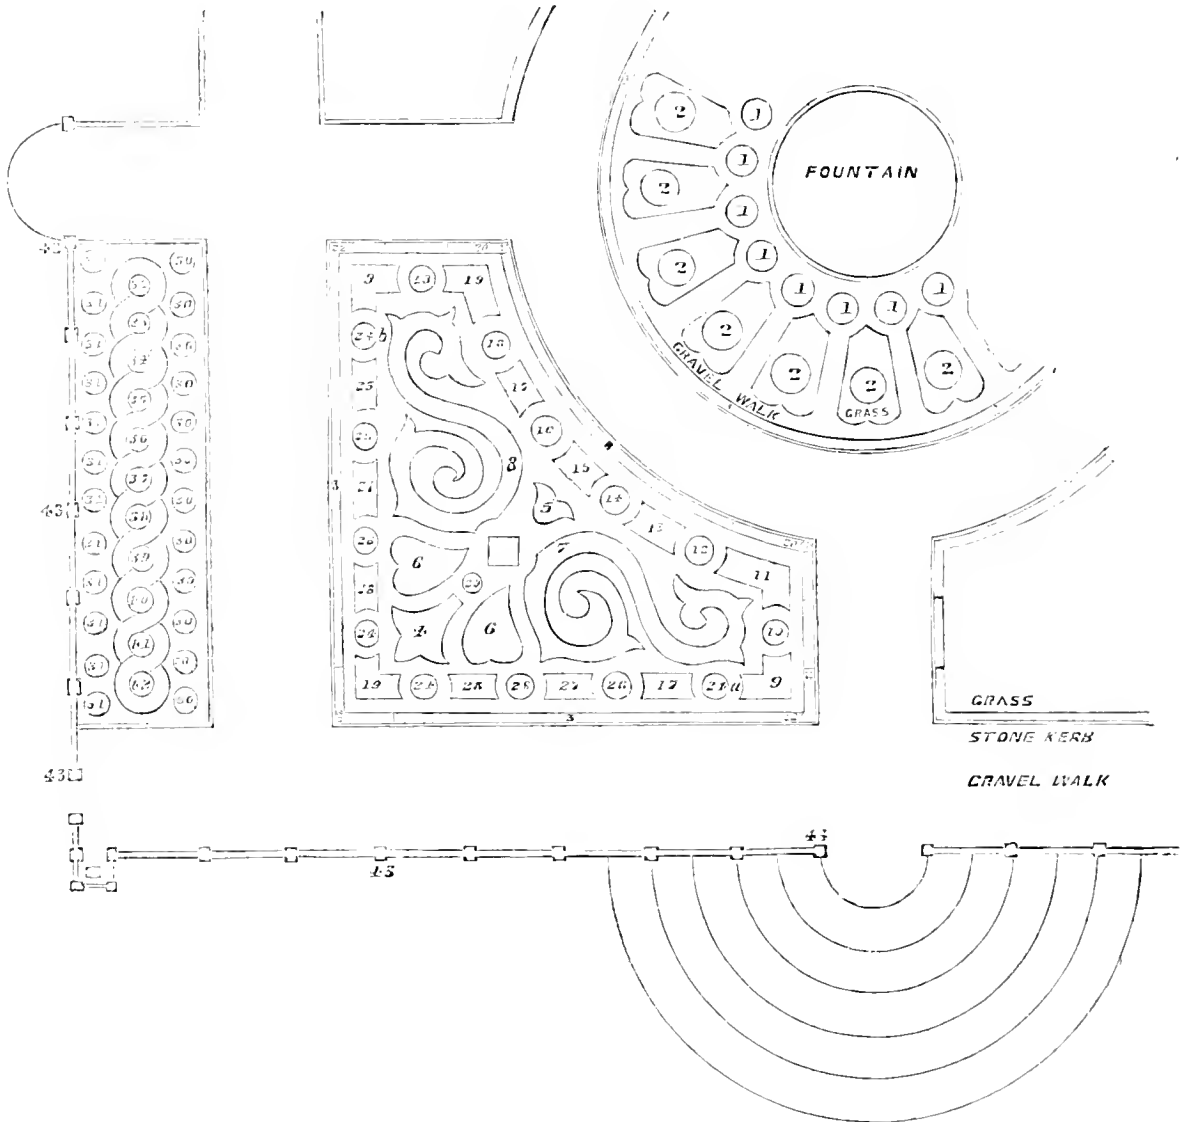

TRENTHAM.

(Concluded from page 415.)

PASSING a neat balustrade and two or three steps we stand on the upper-terrace flower garden, centered with a beautiful fountain with a group of elevated statuary. But for the fountain when standing at the entrance-door of this front, the eye would pass along the centre of the slate terrace, centre walk of flower garden, and centre walk of Italian gardens, right up to the bronze statuary of Perseus

and Medusa close to the lake, a distance of 946 feet. Section 1 on the opposite page will give an idea of that line up to the water.

The upper flower garden is a square, 210 feet each way, the same in width as the conservatory 35 feet, the main front of mansion 140 feet, and width of dining-room 35 feet, making in all 210 feet. The two end balustrades and that

1. Are circles with huge plants of *Humea elegans*, fringed with brown *Calceolaria* mixed with *Pentstemon gentianoides* and *Lobelia speciosa* close to the kerb-stone, which is 4 inches broad. The *Humeas* look beautiful through the water-spray, and come in nicely with the central statuary.

2. Circles surrounded with similar kerb-stones, separating them from the oblong beds of grass on which they are placed. The circles are filled with *Lobelia* and Variegated *Alyssum* mixed.

3. This narrow circle is filled with mixed *Verbenas* of five distinct colours. The inner side is separated

from the gravel by Box-edging 4 inches high, and from the broad walk on the outside by a stone kerb 4 inches high and 4 inches broad. A stone kerb goes all round the outside of panels. The lines of beds inside are Box.

4. *Calceolaria Aurea floribunda*.
5. Irish Yew, spiral, 8 feet high, and *Forget-me-not*.
6. *Verbena Purple King* and dwarf white *Campanula*.
7. *Geranium Trentham Scarlet*.
8. Golden Chain.
9. Brilliant and Mangles' mixed. These, and especially the scrolls, were extra good.
10. Irish Yew and Musk.

11. Variegated *Alyssum* and *Forget-me-not*.

12. *Geranium Golden Chain*.
13. Purple *Nosegay*.
14. *Verbena Mrs. Holford*.
15. *Saponaria calabrica*.
16. *Verbena Mrs. Holford*.
17. *Geranium Purple Nosegay*.
18. *Verbena Mortonii*.
19. *Alyssum* and *Forget-me-not*.
20. *Verbena Brillant de Vaise*.
21. *Humea elegans* and *Brilliant de Vaise*.
22. *Lobelia speciosa*.
23. Irish Yew and Musk.
24. *Geranium Princess Alice*.
24a Golden Chain.
24b *Verbena Mortonii*.

25. *Phlox Drummondii*.
26. China Rose *Fabvier*.
27. *Alyssum* and *Forget-me-not*.
28. *Geranium Baron Hugel*.
29. *Humea elegans*.
30. *Lobelia speciosa*.
31. *Gazania splendens*.
32, 42. *Trentham Scarlet Geranium*.
33, 41. Mrs. Lennox ditto.
34, 40. *Ivy's Masterpiece* ditto.
35, 39. Golden Chain ditto.
36, 38. Kingsbury Pet ditto.
37. Countess of Warwick ditto.
43. is placed opposite to some of the plinths and pillars round the balustrading, all of which are supplied with vases and filled with different shades of *Geraniums*.

in front are richly ornamented by vases on plinths and pedestals, about 17 feet apart.

Of the beauty of this upper flower garden, its artistic tracery, masses of flowers, beautiful statuary, and handsome

turns and vases on the balustrading, with a small temple at the south-east and south-west corners, we should not be able to say anything to please ourselves, and, therefore, feel much pleasure in being able, through Mr. Henderson's

kindness, to present our readers with a plan of the fourth part of this garden, that they may see at once what we should fail to describe. The other three quarters are the same as that given, so that our young friends who feel disposed may make a full plan for themselves.

The centre is the noble fountain with its elevated statuary of Naiads, water nymphs, &c. The fountain has a broad kerb of stone.

Though each of the four panels is a counterpart of the rest, it will be observed that each panel is planted on the principle of insuring a great amount of variety. The Yews and Humeas also formed a nice connecting link with the Humeas round the fountain, and did away with all impressions of monotonous flatness. The chain pattern at the side was a gem of beauty. The rains had slightly injured the circles of Geraniums, but the Lobelia and the Gazania were in their glory.

We now pass down the wide platform semicircular stone steps, six in number, and enter upon the central walk of the Italian panelled-garden. This walk is 40 feet in width. The distance from balustrade to lake is rather more than 240 yards. The width across of this Italian garden is altogether three times that of the upper flower garden, or 210 yards, the ground extending equally to the east and west. On each side of the steps in front of a wall that supports the south balustrade of the flower garden is a border of flowers, among which that old favourite *Salvia patens* was conspicuously beautiful.

Besides this wide walk in the centre of 40 feet, there are also wide walks at the north end next the flower gardens, and across the lower end behind the balustrade that separates

the garden from the lake. On the same level as the central walk there are also two longitudinal walks, one on each side, 25 feet in width; and besides those at the ends, there are two more cross walks which divide the space into six divisions, not equal, but the two middle ones so much larger than the four end ones as to be something in the same proportion as five is to two. The beds in these panels are in two compartments, nearly on the general level of the gravel walks, but with sloping banks and lower levels all round and between them. All these beds have a raised edging or ridge, a foot in height and as much in breadth, of various things—as Oak, Box, Yew, Berberis, Cotoneaster, Ivy, &c. Each of these six panels or gardens has a fountain in the centre, the largest two in the two middle ones—that is, six in all, three on each side. The centre of these fountains is 105 feet from the centre of the middle walk of 40 feet, which makes 210 feet from fountain to fountain crosswise, and thus the three fountains on each side are in direct line with the east and west-end balustrading and vases of the upper flower garden.

Both sides of this garden are bounded by a sloping bank and raised terrace, with walk, &c., some 4 feet above the level of the panelled garden. On the west side this is separated from the park by a shrubbery of ornamental trees and evergreens. On the east side it is separated from lawns and shrubberies by an arched walk covered with creepers, &c. This as well as the position of the panels, or beds, will be seen by section 2, which takes in half the width across from the arched walk to the broad middle walk. Take the lower line of figures as references, the upper giving the distance in feet.

and notwithstanding the masses of plants required elsewhere, these too were grouped with the gayest colours. This, also, was done to a certain extent this season, and a number of large beds were brilliant with annuals in the end of August, and others had been quite as beautiful when the family were there to see them. Circumstances to which we need not here allude render it desirable to lessen the vast masses of bedding plants; and though, no doubt, a little may be borrowed from showy annuals, more than a beginning has been made to fill the beds with permanent plants—that is, that will require less looking-after. Many beds have, therefore, been filled with China and free late-blooming Roses; others with Berberry and various dwarf shrubs of striking foliage; and we are convinced that when all, or mostly all, the beds are done in this way, it will present a much better contrast to the present rich flower garden—will yield on the whole much more of the pleasures of variety—will call for even more plant-knowledge and cultural skill—and, if not so brilliant in summer, will present from the windows of the mansion a far more effective picture in winter and spring.

This will likewise show the level of the beds, with slopes, and the low level of 11 feet in width all round each compartment.

Besides the plants of Yew and upright Cypresses, the most of the beds in these compartments were of large size,

In one striking feature of this garden we noticed a change since our previous visit many years ago. Then there were the finest-headed specimens of standard Portugal Laurels

we had ever seen, grown in large boxes to resemble Orange trees, and vicing in size with the largest Orange trees imported at times from Italy and the south of France—such as may be seen at Wrest Park, Bedfordshire, and Holland House, Kensington. Set at regular intervals of from 70 to 80 feet apart by the sides of the walk, the deception, as to Orange trees, when looked at from a distance was complete, and they were even more beautiful in winter than in summer. The terrible frost of 1860 and 1861, however, settled their beauty, the elevation of the roots in the boxes no doubt rendering their destruction more easy. Nearly two years ago very nice plants were obtained from Messrs. Lane, of Berkhamstead, which now average (and the plants are very much alike), 5 feet in height of clear stem, and $4\frac{1}{2}$ feet in diameter of head, and all look healthy and vigorous. The mode of planting by Mr. Henderson, as likely to guard against severe frost, is worthy of especial notice. To keep up the idea of Orange trees, boxes are still used. These are very neat, 3 feet 8 inches on the square, and 1 foot 10 inches deep, with 10 inches of stone below that, on which the bottomless boxes rest. The plants, then, were carefully planted in the ground, the soil rising as high only as the top of the stonework and not at all into the box. At present, to keep up the deception the box is filled with fern, so that a visitor that did not know otherwise would think it was merely used as mulching. A false bottom of slate is to be put across near the top of the box, and that covered with soil will give the idea that the planting has taken place in the usual way. Security and appearances, and, perhaps, giving in to a prejudice, harmless, however, will be combined. The boxes are placed on the lawn by the sides of the walks. There are three dozen in all, nine on each side of the wide central walk, and nine along each of the two longitudinal walks on the side next the panel gardens. They are so regulated that a box stands near the corner of each of the cross walks.

The raised side terraces of these gardens are embellished and enlivened with massive seats, statuary, and vases; but the most conspicuous of such objects, in an artistic point of view, is a colossal group of bronze statuary at the end of the middle walk, close to the lake, representing the triumph of Perseus over Medusa, the only sister among the dread Gorgons that was subject to mortality, and whose very look turned all who beheld it into stone. And no wonder, for the severed head held in the hand of Perseus has not only serpents entwined in the hair, but every drop of blood as it oozes out becomes a serpent, and thus enough of them are the whole, with their progeny, to keep in countenance the fable, and enable them to spread over the whole of Africa. We presume there will be little difference of opinion as to this statuary when looked at by the eye of the anatomist, the sculptor, or the painter, and yet from the jar it gave our own susceptibilities we might question its fitness for the position in which it is placed. We seemed instinctively to long for a group of the Graces; something like the statue on the hill, to commemorate family honours; something or anything calculated to arouse thoughts of peace, hope, goodness, and happiness, as more in accordance than "Gorgons dire," with the elegant refinement and beauty of these gardens, and the charms of the clear, placid lake, with its side background of ancient Oaks, not only speaking of the past, but in their health and luxuriance inviting us to look forward to the "good times coming," which no doubt they will be privileged to witness.

The waters of this fine lake consisted originally of the stream of the Trent, arrested by means of an embankment thrown across the lower end, but in floods so much mud was carried in, that silting-up seemed merely a question of time. To remedy this, Mr. Fleming undertook the onerous task of changing the course of the river, and supplying the lake from a clear rivulet, and this also enabled him to drain a miasmatic marsh of many acres, and turn it into part of the extensive pleasure grounds. Neither he nor Mr. Henderson, however, with all their care, have been able to eradicate the dread American Waterweed, which is threatening to take possession of our best sheets of water, and become a nuisance and a hindrance in all water-communications by canal or river. It is, however, pretty well kept under at Trentham; but we fear there is little chance of completely eradicating it, unless the bottom and sides were thoroughly macadamised

and concreted, as at Carton, and no mud allowed to accumulate.

With two or three unconnected remarks we will for the present bid good-bye to Trentham. First, as respects visitors to gardens. Through Mr. Henderson's great kindness we were enabled to take a leisurely survey, and obtained from him all the information we asked for. The suggestiveness of much as to valuable practical details will be our apology for this ill-arranged lengthened outline of the place. The being treated as a privileged person, and not as a mere casual visitor, rendered it possible for us to do so. As far as we know, there is no objection to visitors; but then when they are so numerous as at Trentham, the time allowed for parties in general must be very limited—little more than a quiet walk through. In places far less than Trentham we have heard of endless complaints on this score, especially from people who had come from long distances. In the latter case it would always be advisable to make a distinct arrangement beforehand. Even in rather small places there is also often something like a grievance because parties are not attended by the gardener. Come when they will, they expect he will be in readiness to receive them. If the gardener were to intrude upon them when particularly engaged that would be quite a different thing. No class of men have done so much as gardeners to oblige and serve the public, and often with scant courtesy for their trouble. The public should never get so much attention as to interfere with duty to the employer, who pays the gardener for his services. If general visitors are attended by any one deputed for that office, they should be content and thankful. No attempts should be made to interfere with the time or the engagements of the gardener in such circumstances. On this account, too, none but private friends should intrude as garden visitors after working hours. We candidly state that for next to perfect strangers we have lost many evenings from this practice, because we could not pleasantly say No, and have had to make up by want of sleep in consequence. In all popular gardens in densely-peopled neighbourhoods, it is a good plan for gardeners and for visitors to have a few days or afternoons in summer set apart in which visitors are admitted without attendance. In such cases visitors should rigidly confine themselves to the departments thus free of access to them, and scrupulously refrain from all that is forbidden. The regulation-breakers are only confined to a few of the "fast" order, who think it makes them big and like gentlemen—save the mark!—to show off their airs and would-be independence, for which the best reward would be a good ducking in a horse-pond, to take their starched bad manners out of them. Mind, we know nothing of the conduct of visitors at Trentham, except what is right; but the numbers that resort there have brought these ideas to our mind and our pen. It is always a misfortune when the misdeeds of a unit or two tend to deprive thousands of worthy people of a privilege and a pleasure.

Secondly. Though in many places we have seen finer trees and plantations, and bolder and more striking scenery than at Trentham, it would be difficult or next to impossible to find any place at all comparable in size, or, indeed, of any size, where a greater attention is evinced to order, neatness, and superior culture in every department. That attention is seen in everything, from a Pine Apple down to an annual Candytuft. This is all done with the greatest attention to economy, the £ s. d. matter is kept steadily in the foreground. No doubt Mr. Henderson has advantages in having his own work-horses, &c., and being thus far independent of beseeching for help in this way; but still there can be no question that many in small places would here gain valuable lessons on economics, and the undesirableness of having even one corner which they would be ashamed for other people to see. The peculiar mode of management adopted, there being no foreman properly speaking, must require from the superintendent an amount of energy, bodily and mental, constant thought, and never-ceasing care, of which none can form a correct idea, except they who have been placed in similar circumstances and under such weighty responsibilities.

And once more. But for exercising too much liberty, we might direct the attention of our younger brethren to the superintendent of these gardens, as another evidence of what can be accomplished in surmounting difficulties by

patience, activity, attention, self-dependence, and self-culture. True, there are but few Trenthams to reward the aspirant for fame and distinction; but the smallest garden will be made the most of in proportion to the activity combined with intelligence brought to bear upon it, and just in the same proportion will the gardener be happy and comfortable in his work. We would ever advocate self-culture in intelligence, not so much to fit a man for a great place—not so much to enable him to keep it when he gets it—not merely to insure him any social distinction and elevation—but chiefly and above all, when united with self-control and moral principle, as the means for insuring happiness and elevated enjoyment. His house may not be large, nor the most comfortable, and the locality may be so secluded that he can have little social converse; but the mental wealth of palaces, and mansions, and noble halls, and institutes of learning, are all waiting for his use; whilst in books, the best of friends, he can hold intimate converse with the great and the good of every age and clime. Thus the deliver may not only have the self-respect of a gentleman, but be treated like one, in all intercourse with those superior in station. We are happy to know numbers of such men who, from their self-acquired and right-directed intelligence, realise in the capacity of servant a seemingly greater delight in the productions of the garden than the employers who pay for it all. So true is it, that the greatest activity in toil may ever be associated with the greatest pleasure and elevated enjoyment.

WORK FOR THE WEEK.

KITCHEN GARDEN.

As it is now a good time to start the first crop of Asparagus, Rhubarb, and Sea-kale, we trust that a few remarks on the forcing of these things may not be unacceptable to persons of small experience. The old plan of forcing Sea-kale is a most expensive and unsatisfactory mode; expensive on account of the breakage of pots and the loss of labour, and unsatisfactory on account of the want of a more perfect control over the whole proceeding. The best as well as the most economical plan is to take up the roots and force them in a body together after the manner of Asparagus. To accomplish this, it is, of course, necessary to grow strong roots in the kitchen garden for this special purpose. We say strong, for no mode of forcing can produce good Sea-kale unless the roots be strong to begin with. Such roots being available, they may be forced in any structure which will exclude light and the severity of the weather. They can be forced in frames with a double mat nailed down over the glass. They can also be grown under a mere wooden box, but the general practice is to force them in the Mushroom-house. A sunken pit is also useful, and this should be 2½ feet in depth, 18 inches for the fermenting matter, and 1 foot or nearly so for the crowns to rise and for any opaque covering considered necessary. The strongest fermenting matter to be placed 18 inches below the crowns, and the roots upon it, merely covering the hot manure with old leaves. The crowns to be set thereon as thickly as they can stand and filled up between with light soil, leaf mould, or old tan. In a couple of days, if the heat is found to be too strong, it can easily be reduced by the application of a little cold water. Rhubarb is forced successfully in a similar way. The roots, however, may be placed in large pots and set on flues or other warm surfaces. Asparagus requires the same treatment as to bottom heat as Sea-kale, with this difference in top management, that whereas Sea-kale cannot be kept too dark, Asparagus should have all the light this dull season affords, and abundance of air when the weather is mild in order to produce colour, without which there can be but

little flavour. Asparagus to have 4 inches in depth of soil over the crowns. The occupation of the ground by crops suitable as food for a variety of insects in the course of a series of years, brings a numerous collection of such depredators into a garden. The application of methods for their extirpation often taxes the ingenuity of a gardener to a considerable extent. The analogy existing between insect and vegetable life restricts the choice of means, for the substance which may be provided for the destruction of one may injuriously affect the health of the other, hence the necessity of caution in the use of materials. There is, however, one substance not open to any objection which may now be used with advantage on land from which the crops have been removed—viz., lime. Ground cropped the preceding season with Carrots, Parsnips, and Potatoes, and found, as is frequently the case at this time, infested with grubs, &c., should have a good dressing of lime dug in, or, if that cannot be afforded, the soil should be turned up in ridges for the winter. *Artichokes* (*Globe*), to be thought of for protection. *Lettuces*, examine the young plants frequently, and dust with lime or soot to check the devastation of slugs.

FLOWER GARDEN.

Now, as the leaves have all fallen from the deciduous trees, there should be a general clearing-up. The leaves and sweepings of the walks to be laid about the shrubs in the shrubbery, and to prevent them from blowing about they should be slightly covered with soil. This mode of proceeding will be much better for the shrubs than digging amongst them and destroying their roots.

FRUIT GARDEN.

Proceed with the planting of fruit trees in open weather, and if the soil is old let each tree have a good portion of new soil about its roots. Pruning and nailing all sorts of wall trees except Peaches, Nectarines, and Apricots, should now be vigorously prosecuted. Leave nothing for the spring which can be done now, every day gained now will give greater liberty for spring operations.

STOVE.

A cautious application of fire heat must still be observed here. Keep the temperature rather lower than otherwise for fear of exciting a premature growth. Cleanliness and a judicious use of the watering-pot should be strictly attended to. A small portion of air may be advantageously admitted on fine days, and will greatly assist in purifying the atmosphere of the house. Many stove plants with large fleshy roots, such as the different varieties of *Ipomoeas*, should now be allowed to become nearly or quite dry.

GREENHOUSE AND CONSERVATORY.

Attend to the removal of *Chrysanthemums* and all other plants as they turn shabby. Some of the early *Camellias* will soon be ready to take their places. Occasional fires will be useful during dull, damp, or rainy weather, taking care not to raise the thermometer unnecessarily high. Every endeavour should now be made to keep the conservatory as gay as possible. In mixed greenhouses see that the young stock of *Heliotropes*, *Geraniums*, *Cyclamens*, *Chinese Primroses*, and other flowers grown especially for winter have nice light situations and regular attention as regards watering. In addition to keeping the conservatory gay with blooming plants, let the arrangement of the house be occasionally changed by grouping the plants somewhat differently, and adding a few striking ones, such as *Orange trees*, *Araucarias*, and any other plants of beautiful foliage, with here and there plumes of the *Pampas Grass*, &c., for effect.

FORCING-PIT.

This structure to be kept fully occupied with all the different plants usually employed in forcing for the decoration of the conservatory or drawing-room. In successfully forcing many plants the application of bottom heat will be found indispensable; a well-constructed tank is, therefore, a necessary adjunct in this department.

PITS AND FRAMES.

Keep the stock in these structures well ventilated, and the surface soil of the pots frequently stirred. Dust with sulphur *Verbenas* and other plants attacked with mildew. Be particular in keeping the interior as dry as circumstances will permit. Prevent drip as soon as perceived.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

In all departments might say, "Another of the same, much the same as last week." Obtained a little stubble for packing up the tops of Celery. We noticed the mode of blanching by means of allowing the plants to grow through drain-pipes set upright, at page 410. It so happens that we practised a similar mode many years ago, and it does well for early Celery when the receptacle is well filled; but then the mischief is in proportion to the porousness of the drain-pipes; they were liable to let the Celery freeze in frosty weather. So far as mere blanching is concerned, we have had large early heads pretty well blanched by merely tying the plants close together; but in that case, too, if nothing else is done, the Celery when blanched is apt to suffer from frost. Packed a little litter round the stools of Globe Artichokes, after placing a mound round them of dry leaf mould, and burnt clay and rubbish. Went over some vegetable quarters, and pulled off the yellow leaves from Brussels Sprouts. We attribute more than ordinary of these yellow leaves to the heat and drought of the summer. Gave plenty of air to our Asparagus in a frame, as with mild heat it has come in sooner than we expected, but it is also good and very useful. Put in some more Sea-kale and Rhubarb, to give a good supply about Christmas time. Find that some Camelliflowers that were put into a thatched shed have been much improved in appearance, the heads being particularly white. Earthened-up a little bit more of a Mushroom-bed, and kept the house a little warmer, about 65°, or a degree or two more for a few days, as we wanted a good many large and small for some days; will then let the atmospheric temperature fall to 55° as the average. Had most of the rubbish from flower-beds, Pea haulm, Scarlet Runner haulm, thrown up into a heap along with some leaves and litter, and it will be most valuable for forcing, and helping on many things. When we do not use such materials in this way, we use them for a bottom, and for throwing heat into rubbish-heaps—those mixtures of everything in a garden, soil from pots, refuse from vegetables, weeds, &c. This heating is a capital thing for setting all seeds germinating, and then getting killed for want of air to breathe in. Took also a little more turf from the roadside, and it is stacked up like heaps of miser's gold. When we can follow our choice we like these heaps to stand for a twelvemonth, and to be pretty well aired, and then cut down and used without any of the frequent choppings and turnings which many people recommend, as the more chopping and turning the greater the waste of fibre. We have made these heaps of turf of different sizes, but we now make them as follows:—Set off a yard in width at bottom, build that widening so that at 3½ feet in height the heap will be 3½ feet wide, then take in and finish with a span-roof 18 inches to the apex. In building, when about 15 inches from the bottom, place small circular drain-tiles from end to end in two rows, with a little space between them to let air circulate freely. Do the same about 3 feet in height, and one row in the ridge. These mellow and sweeten the soil without greatly injuring or wasting the fibre. The top is then thatched with turf, grass side upwards, and a few wooden pins driven in to keep the turves in their place. As soon as the turf takes hold no rain will penetrate; and so dry are these heaps kept, that when using them a little water is often wanted to make them mellow enough for potting. The drier the turf is put up the sooner will the soil be sweet and fit for use.

FRUIT GARDEN.

Much the same as in preceding weeks. Made up two slight hotbeds with leaves, &c., and filled the two frames of two lights each with Strawberry plants, having previously removed all the yellow and a few of the larger leaves; and, having picked off with a pointed stick a little of the surface soil, and made sure there were no worms in the pots, top-surfaced with rich compost pressed firm, and set the pots on the bed, allowing them to sink in the leaves an inch or two. This will just move them gradually, and render them fit to go into places where we apply to them a little more heat than merely keeping frost out. We do not plunge these pots, for sometimes at this season even no great depth of tree leaves will heat violently, and nothing injures Strawberry plants more than too much heat at the roots. Even

as left standing on the top of the leaves the heat must be watched, and then if very mild, only from 60° to 65°, the pots may be partly plunged. In this respect, also, care is necessary so far as these early plants are concerned; and if the pots are plunged at all, or even partially so, it is a good plan to have the bottom of the pots resting on a hard substance—as a deal board, for whatever at this early period has a tendency to make the roots run through the bottom of the pots, has also a tendency to give you a fine crop of foliage with but little fruit. The allowing the roots to extend after the fruit is set is quite a different affair. Meanwhile we would say to all who cannot undertake the trouble of watching these mild hotbeds, that they will do better if they put their plants into a cold frame or pit, or upon any shelves in their houses that may be vacant. Suitably attended to there, they will move gradually as the heat is increased. Looked over fruit-room, and find that Pears are not keeping so well as Apples. Many boys and labourers are fond of a mellow Pear, when they would be too mealy for the parlour table.

ORNAMENTAL DEPARTMENT.

Proceeded with cleaning up pleasure grounds, rolling walks, potting and fresh-regulating plants in the houses, and finished a little stove-house, the repairing of which has been in hand for some time. Our Fig-house and this little stove-house are in the same little low range, having previously been Pine-pits. The walls and floor were sunk below the ground level 3 feet. The fruit wall outside was 1 foot higher, and the back wall 4 feet. The house was 14 feet wide inside measure. There was a short hip at the back, of glass, which made the highest point of the roof 8½ feet from the floor. The house was heated by hot water, two pipes a yard from back wall, and three pipes 1 foot from front wall. Over these pipes we had a platform of slabs and a path in the middle. The beds were rather wide to be nicely managed, and when a few people went in they could not well get out again. The wall-plates, &c. being decayed, we were allowed to make a little alteration provided it did not cost much. On that account we were afraid to meddle with the old heating-pipes in case they should want a good deal of tinkering at our hands. We, therefore, after clearing and painting, left them as they were. Air was previously given by moving the sashes of the roof. In putting fresh wall-plates we raised all the walls round from 18 to 24 inches, raising the roof, after the glass was off, as we did so. This gave headway enough to have a pathway all round and a table in the centre, with a platform at back, and a shelf at the ends and front. The walk is about 28 inches wide, the front and end platforms 18 inches wide, the back platform 3½ feet wide, and the central platform 4 feet wide. The front shelf, end shelves, and back platform are supported by a wall all round 15 inches in height, and then by little pillars in front of the pipes. That will leave room all the way for a little bed near the pipes for small Ferns and Lycopods, which will be allowed to hang over this dwarf wall as they grow. Wires extended on the sides from pillar to pillar will also be a good support for creepers to run along that like both heat and shade, and that have fine foliage, as the *Cissus discolor*. The centre platform is supported on stout oak posts standing on a raised row of bricks laid in cement, to keep the posts from the damp of the floor. The space underneath has been drained, and, after a lot of brickbats, has been covered with heath soil and loam, and that too will be planted, or rather is planted, with Lycopods and Ferns. The oak posts will not be painted until next summer, and then we will sand them to resemble stone, and will do the same with skirting-boards, brickwork, &c. The part of the posts out of sight was well coated with pitch. The platforms are laid across oak bearers similarly pitched. The platforms themselves are stout boards of the necessary width well pitched on both sides, just put close together, and then all covered with clean little stones, or shingle procured by washing road drift, and keeping all these of one uniform size or nearly so. On this the plants will stand. We forgot to say that in raising the wall we left openings for ventilation back and front, which can be easily opened and regulated without any great mechanical contrivance. The ventilators are small boards hung on screws to act as a pivot-joint. We can now go round the little place and see and examine every plant in it. It has cost us a little labour, but the pleasure

well repays it. We might not have thought of doing so but for the necessity of repairs. We have also left an opening, so that we can drill a hole for hot-water pipes in the centre if ever they should be necessary. Baskets will be suspended over the pathways, and if not, we could have a broad shelf there. From floor to glass all may thus be occupied.

This may be interesting to some correspondents who are making inquiries as to arrangements. If one good turn deserves another, then we should like to propose a few questions as to the pitch. The sort we used was in lumps, such as is employed by undertakers; but there is such a collection of materials very much alike under the name of bitumen, asphalt, pitch, &c., that we really do not know which is the particular sort, or what would be best for the purpose of keeping out water and yet drying at once and giving out no scent a few minutes afterwards. When used very hot and, of course, melted, we found it would not part freely from the brush unless there were a little grease mixed with it; but if we happened to put in too much it did not dry quickly on the boards. And, once more, Does any one know experimentally how such pitch-painting would stand on wood out of doors under the variations of our climate—heats and colds, &c., and what would be the cost of good pitch at wholesale prices? We cannot say that we fancy painting even rough fences with tar, and we rather think it sometimes helps to rot the wood it is intended to preserve. But if such mixtures are to be ground up and sold for white lead, it is high time something more durable could be had. We know that some of the very best paint, at least paid for as such, is apt to rub off like chalk in less than a twelve-month.—R. F.

COVENT GARDEN MARKET.—Nov. 28.

The market continues well supplied with produce of all kinds, and quotations are unaltered. Of foreign Grapes and Melons there is a plentiful supply. Home-grown Apples and Pears consist of the same kinds as named in previous reports. From France there are some magnificent examples of Reineette du Canada, Poime d'Apl, and Calville Blanche or White Calville; and in Pears of Uvedale's St. Germain of immense size, Hugh Moreau, Easter Beurre, and others. Sea-kale is coming in in greater quantity; but the demand having increased, former prices are maintained.

FRUIT.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

HEATING (*J. Mussett*).—Such a notice is merely an advertisement, and if we inserted it we could not refuse insertion to many others.

SOWING CINERARIA MARITIMA (*E. D. G. C.*).—Sow in the first week of February in a temperature of 65°. One part loam, one part leaf mould, and as much sand as will make the whole sparkle will suit it very well. It is a plant easily raised from seed. It, however, does not acquire its silvery hue the first year from seed, and we always sow in July or August and preserve it over the winter. We are puzzled to know how you managed to get a temperature so low as 44° last August. The cuttings could not succeed well in such a temperature. We find damp the greatest obstacle in striking autumn cuttings, and that the weak wiry side shoots always strike the most readily.

COVERING FOR PIPES IN CUCUMBER-HOUSE (*J. K.*).—The oak boards will answer, but slate will be better, inasmuch as it lasts so long, allows the heat to pass more freely, and there is no risk of breeding fungi in the soil, as is the case when the wood begins to decay. Heart of oak, however, will last a long time, but slate we consider the best, and we have used it with great success.

PINK APPLES DECAYING (*Idem*).—As soon as your Pines show the least signs of colouring at the base of the fruit, keep the soil dry and also the atmosphere of the house or pit. The Antigua is not a good keeper under any circumstances, and therefore it should be cut before it is dead ripe and be used immediately. Were you to grow Smooth Cayennes and Black Jamaicas for late autumn and winter work, you would have no difficulty of the sort with them. They are the two best winter Pines.

LOBELIA PAXTONII (*L. R.*).—The merit of *Lobelia Paxtonii* must be determined by each individual's taste. We do not like it so well as we do *Lobelia speciosa*, but we consider it a valuable acquisition. It is very like an old variety named bicolor. In a mixed border it will look well, and so would a row of *speciosa* in front and a row of *Paxtonii* behind it. It is of a different habit and colour from *gracilis*—*gracilis* is light blue, *Paxtonii* is lightish blue and white, the white rather preponderating. We decidedly recommend you to propagate it, and yet not to discard the *speciosa*. They are both good for definite purposes.

SPECIE FIRS FOR LIGHT LOAMY SOIL (*G. B.*).—*Abies excelsa* (Norway Spruce), *Abies Douglasii*, and *Picea balsamea* (Balm of Gilead Fir) we think would answer your purpose. *Pinus austriaca* and the Scotch Fir would also suit you.

NATURAL HEIGHT OF CUPRESSUS LAWSONIANA (*Idem*).—It is a native of California, where it attains a height of 100 feet; but we cannot say to what height it will grow in this country. It is one of the handsomest of the Coniferae.

TURNING SHEEP AMONGST YEW AND OTHER TREES (*Idem*).—Yews poison horses and cows, and it is highly probable that, if the sheep could get at the branches and leaves, they would be poisoned also. We advise you to have them fenced off, or to put some temporary netting or permanent iron-wire fencing round the trees and shrubs.

ADELASTER ALBIVENS CULTURE (*George Sim*).—This is not half such a "miffy" plant as is represented. It grows freely in sandy peat one half, light turfy loam and leaf mould the other half, with a liberal admixture of small pieces of charcoal and silver sand. A rather moist atmosphere, without saturation, is requisite, and moisture standing on the leaves must be avoided. Shade from very bright sun, but give air and light the same as to any other description of stove plant with fine foliage. The heat of an ordinary stove suits it well. Of the plants you name *Alocasia zebrina* and *A. albo-violacea* are the newest; the next is *A. Lowii*. Show the best grown—the Judges will not pass over good cultivation for the sake of novelty; at least, cultivation should be the test of merit.

UNPAVING PLANS (*W. W.*).—The best plan for you to adopt is to dig out a trench round the extremity of the roots and carefully remove all the old soil, preserving every root that can possibly be retained. Pare off with a knife every appearance of a sucker, and replant the roots in fresh strong loam with a little rotten dung mixed with it. Plums do not do well in a light gravelly soil, and if yours is of that quality try and procure some of a more strong and adhesive character. The roots had better not be taken up any nearer to the stems of the trees than up to the pavement, as the trees are old. You may take up the pavement and remove the soil down to the roots underneath it, and close up to the wall, and lay in a top-dressing of the soil we have already recommended; but do not on any account cut back the roots within the limits of the small space between the pavement and the wall. There is a list of the other garden manuals sold at our office on the cover of "Fruit Gardening for the Many."

GRAPE DECAYING (*A Six-years Subscriber*).—We think your Grapes are suffering from mould. The berries are not sufficiently thinned for hanging, and the footstalks consequently mould from want of air. The berries should be thinned so that they do not touch each other. The bunches should be daily examined to see that no mouldy berry exists, and when one is seen it should be taken out immediately, otherwise the disease soon affects the other berries, and the bunch is rotten in an incredibly short time. Your border would be better if it were covered with wooden shutters to keep the roots dry.

CELERY DISEASED (*Idem*).—The Celery is attacked by the fly so common now. Sprinkling the leaves with soot prior to the leaves being attacked with the pest is a never-failing preventive. Strew soot on the leaves now, continuing to pick off those most affected and burn them as you are doing. Be in time with the soot next year, for prevention is always better than cure.

PLANTING FLOWER-BEDS (*New Forest*).—We consider the plan well adapted for planting on the balancing principle; but we cannot swerve from our fixed rule. Send us your proposed planting, and we will say if any error is apparent to us.

GREENHOUSE FERNS (*M.*).—We would add the following to those you have already:—*Asiatum capillus-Veneris*, *A. pedatum*, *A. pubescens*, *Antigramma urophylla*, *Blechnum triangulare*, *Cheilanthes micromera*, *Cystopteris tenuis*, *Drynaria pustulata*, *Hymenophyllum dilatatum*, *Lomaria capensis*, *Notholaena vestitum*, *Platyloma atropurpurea*, *Polystichum capense*, *Pteris serrulata*, *Trichomanes radicans*, in a moist shady place.

HOLLYHOCK AND DAHLIA FLOWERS CHANGING COLOUR (*An Old Lady*).—We shall be much obliged by your informing us of the result from changing the soil; but recommend you to grow some in the same soil as they now grow in—this will be a test. We think growing Dahlias for a series of years in the same soil might render them less vigorous, but would not change all the colours to white.

SELECT PELARGONIUMS (C. J. M.).—*Twenty-four fine-flowering Pelargoniums*: Colossus, Royal Albert, Rosy Bloomer, Censor, Improvement, Ariel, Celeste, Empress Eugénie, Fairest of the Fair, Lady Tamton, Lord Clyde, Mrs. Hoyle, Norma, Princetta, Roseum, Sir Colin Campbell, The Belle, Sunset, Bæchus, Lady Canning, Agamemnon, Merrimac, Viola, Leviathan. *Sir Spotted*: Landseer, Monitor, Conspicuum, Sanspareil, Mr. Hoyle, Peacock. *Six Fancies*: Ellen Beck, Acme, Arabella Goddard, Cloth of Silver, Madame Sainton Dolby, Modestum.

BEANS—*W. H.* wishes to have any approximation to a statistical account of the acreage planted with Beans in England each year, or in the United Kingdom; also which are the principal Bean-producing districts, and whether they are grown to any extent in foreign countries, and, if so, what countries? We shall be obliged by a reply to these queries.

SELECT CHRYSANTHEMUMS (P. A.).—*Twelve best Chrysanthemums, large-flowered*: Her Majesty, Duchess of Buckingham, Jardin des Plantes, Beverley, Lord Palmerston, Talbot, Queen of England, Dr. Ross, Plutus, General Slade, Antonelli, and Cleopatra. *Six Pompons*: Mrs. Dix, Danae, Julie Engelbach, Lucinda, Duruflot, and Julie Lagravère.

ERECTION OF A GREENHOUSE (Economy).—The cost always varies too much with locality and circumstances for us to give an estimate without almost a certainty of misleading. For seven postage stamps you may have from our office "Greenhouses for the Many," which gives full particulars and illustrations.

NEW ZEALAND FLAX CULTURE (N.).—This plant (*Phormium tenax*) has been found hardly as far north as Inverness-shire. It bears the climate of the southern counties of England, and grows freely in the moist climate of Ireland. It will, therefore, no doubt prove hardy with you in the south-west in a sheltered situation. The plant is easily propagated by division of the root. The divisions may be taken off in April and planted at once in loamy soil in their final quarters. The seeds should be sown in March in rather strong loam, scattering them thinly over the surface, and covering with a thickness of soil equal to that of the seed. Place the pot or pan in a cucumber-frame or any place with a nice gentle heat. Keep duly supplied with water, and when fairly up gradually harden-off and place in a cold frame. Prick them out in a cold frame when sufficiently large to handle, making the soil moderately rich by adding some leaf-mould or well-rotted manure to it. Keep rather close until the plants become established, then admit all the air and light possible, and give copious supplies of water. The plants should have the lights put over them in severe weather, some bracken or straw being placed on the lights in long-continued frosts. Plant out in the April following. They require a moist soil and climate, and will no doubt do well on the margin of your lake. We should advise you to try an established plant or two first, and see what effect the climate and soil have upon them before you risk a number of plants.

ASPLENIUM VIVIPARUM CULTURE (B. E.).—We grow this in a moist stove fernery, and have no necessity to employ a bell-glass. It does well in a temperature of 55° by night and 65° by day in winter, and one of 65° by night and 75° to 85° by day in summer. It has fronds much resembling Fennel, and bears a quantity of little plants on its fronds as they become mature. It usually grows about 1 foot high, and does well in a six-inch pot if a moderate-sized plant, a nine-inch one being sufficient for the largest plant. Cocoa dust is a good material for growing it in, and it requires the same amount of moisture as any other stove Fern, the Filmy-Ferns excepted.

TYNNINGHAM MUSCAT GRAPE (Old Subscriber, Nottingham).—This is a very fine variety of the Muscat of Alexandria, and you can procure it through any respectable nurseryman; but should you have any difficulty, write to Mr. R. Parker, nurseryman, Tooting, near London, and you will be sure to obtain it.

DRACENA HELICONIFOLIA AND D. SIAMENSIS (W. T. T.).—These cannot be successfully cultivated in a greenhouse where the temperature falls below 50° at night in winter. They do moderately well in a warm greenhouse in which the temperature rarely falls to 45° at night; but a stove with a temperature in winter of 55° at night and 65° by day, and in summer of from 60° to 85° is more suited to their requirements. We should be only deceiving you were we to say that they would thrive in a cool greenhouse. You may keep them dry during the winter, when they will bear a lower temperature, and probably they might be wintered safely in your cool greenhouse. Anthurium aculeate is not worth growing by those whose space is limited. It is well enough for botanical collections; but, as a fine-foliated plant or ornamental-leaved—which are all the charms it possesses, or even are claimed for it—we think it is one of many that could well be spared. We know of no other attractions beyond those already seen by you.

CLOTH OF GOLD ROSE NOT FLOWERING (S. R. Drake).—This Rose, at the very best, is a shy bloomer. A southern aspect is more suitable for it than an eastern one, as the sun will not be long enough upon it to sufficiently ripen the buds; therefore they come blind or make wood only. We should advise you to thin out the shoots and admit sun, light, and air to them by not nailing-in the shoots nearer than 1 foot apart. If you could conveniently dig out a trench about 4 feet from the stem and down to the lowest roots, which you would cut and then fill in the trench with rather poor soil, we think it would not then grow so rampantly as it does, and this probably might be the means of causing the wood to ripen better and afford more flowers the season after next. We thoroughly understand what you mean by blind shoots.

NAMES OF FRUIT (W. H. C.).—Your Pears are—1, Beurré Diel; 2, Chantrel; 3, Vicar of Winkfield; 4, Passe Colmar; 5, Beurré de Rance; 6, quite rotten; 7, unknown. (W. Gill).—It is not Doyenné d'Été, but Beurré Benger. (A Subscriber from Wales).—Your Pear is Red Doyenné. You may have in addition Joséphine de Malines, Winter Nelis, Jean de Witte, and Bergamotte Espéren.

NAMES OF PLANTS.—Some of our correspondents are in the habit of sending small fragments of plants for us to name. This requires from us such a great expenditure of time that we are compelled to say that we cannot attempt to name any plant unless the specimen is perfect in leaves and flowers. (Jarman).—It is not a Fern, but *Pilea muscosa*, the Pistol or Artillery Plant, belonging to the natural order Urticæ. (W. H. M.).—1, *Hymenophyllum tunbridgense*; 2, *H. unilaterale*. (M. A. S.).—*Cystopteris fragilis*. (W. H. Mayne).—Nos. 1, 2, and 3, *Trichomanes radicans* in different conditions; 4, *Adiantum cuneatum*, certainly. (A. T.).—1, *Litochroa aurita*; 2, *Pteris arguta*; 3, crushed, apparently *Tetrahæa ericifolia*; 4, *Monochaetium ensiferum*. (T. P.).—Your Ferns are—1, *Pteris longifolia*; 2, *Pteris cretica albo-lineata*; 3, *Pteris hastata macrophylla*;

4, *Pteris cretica*; 5, *Pteris hastata*; 6, *Pteris serrulata*. (B. H. W.).—1, *Pteris serrulata*; 2, *Pteris tremula*; 3, *Selaginella pubescens*; 4, *Pteris hastata macrophylla*; 5, *Athyrium Filix-terre*; 6, *Torenia asiatica*. We do not go beyond this limit. (S. S. Woodlands).—*Pteris serrulata*. (A Scotchman).—*Rhynchospermum jasmynodes*. (T. C. S. Tynen).—*Hymenophyllum tunbridgense*. (A Subscriber to the H. J.).—Your bulb is *Sternbergia lutea*, one of the *Amaryllidaceæ*. It is a native of the South of Europe, but we do not know whether it is found in Palestine. It has been cultivated in our gardens for more than two centuries.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

COMMON SENSE APPLIED TO EXHIBITING AND SELLING.

At page 401, "EGOMET" touches on various matters in answer to "AN EXHIBITOR IN A SMALL WAY." In answer to the same exhibitor, I would reply that "EGOMET's" observations are well worthy of attention. I, too, am an exhibitor in a small way, and understand how difficult it is for owners, especially when not present at the shows, to conceive that birds, which by constant scanning they have considered the "pinks of perfection," remain unnoticed. The fact is, that Judges, as a rule, see more impartially than we do, and as generally they judge ignorant of ownership, we ought to give credit for honesty in carrying out the very difficult task of trying to please everybody. It is impossible perhaps, that such practised eyes as Mr. Hewitt's or Mr. Baily's can frequently examine closely the same pen and not occasionally recognise the proprietor; but because the well-known pen obtains the blue ribbon, we have no right to blame the Judges. Occasional mistakes there must be: sometimes we may get the benefit, as a poultry friend lately told me I had; sometimes we may get the loss, as I have also done:—these are matters that the greatest care, the most precise rules, the strictest judging by points, can never wholly avert.

Though less fortunate than I had hoped to be at the Crystal Palace, I might perhaps have been tempted to Birmingham, but for the peculiar method of entering and the hints about the small size of the pens. I know I have seen many valuable birds considerably damaged by this, and it seems a pity that "the mother of shows" should act so unwisely in this particular. As regards Manchester, I think a greater point against the Show than the days on which it is held is the character of the prize list; but on this point, after Birmingham and Manchester, I may with your permission say more, as I hope to analyse those Shows as to entries, as I have done the London Shows. My only experience of a Show on the same principle was Sheffield; there the classes filled very badly, and to many, myself included, bare honour was all that was gained, as the prizes have never appeared.

Let "EXHIBITOR IN A SMALL WAY" take the Crystal Palace catalogue and prize list; he will see many exhibitors of pens from one to six in number, amongst the prizetakers, whilst he will also see many entering largely, yet not achieving success in proportion. "ONE WHO DOES NOT MIND THE FORMALITY OF AN ADVERTISEMENT," also gives him advice with which my experience quite agrees. Get a name for a breed, and even without an advertisement he will sell birds—at least I have done so largely this year, purely, as I presume, on the strength of my success in exhibiting, for I have never advertised. I think it is time now, especially as some little time ago I saw an advertisement of birds as from my stock by a former purchaser. This leads me on to "CONSTANT READER;" and I may say that in each case of application I have sent prices of birds, but requested post-office order first. All except one did so, and several expressed their satisfaction, nor have I ever had a complaint. After you have supplied a few to their satisfaction, you have them as persons to whom you may refer others. "CONSTANT READER" may, perhaps, in future, send his post-office order not to be payable for ten days. I have trespassed so largely on your space that I must leave my remarks on "BRAHMA POOTRA" till after the two great Shows to which I have alluded.—Y. B. A. Z.

CREVE CŒUR FOWLS.

I HAVE just read your account of the Crève Cœur fowl, and, I am pleased to say, I can endorse M. Jacque's good opinion of this bird. I was rather prejudiced as to its

success, thinking that a bird coming from a warmer climate to one of a colder and more changeable character would not succeed, but hearing of their extraordinary merits in egg-producing I was induced to try them. I consequently wrote to a Parisian dealer for three pullets and a cock. They arrived, but in very bad condition through their long journey, misdirection, and cold weather. Their eyes and heads were much swollen, and they became totally blind and discharged at their nostrils, which gave me cause to regret my bargain, and seek information as to the best cure.

Well, after getting them over their first trouble, I had my fowl-house removed to a more sheltered spot and made warmer; I took particular care in the feeding, and they soon commenced laying, although they were hens and not pullets as described by my French friend. It was now November, and every egg was valued. They continued laying large eggs, averaging $2\frac{1}{2}$ to 3 ozs. each, and several were laid weighing $3\frac{1}{2}$ ozs. They each laid about five or six eggs in the seven days, and continued till New-year's-day, when two of them stopped, the other continuing till a fortnight afterwards. I then was loud in my praises of this fowl, and recommended it to all my friends in preference to all others. They have a double merit in being extraordinary layers, and first-class table fowls. They are superior to the Spanish as layers in winter, are much hardier when once acclimatised, easy to rear, and fledge quickly. Their superiority to the Dorking is that they are better layers, produce larger eggs, stand confinement, and the chickens are hardier and more easily reared. They are equal to Dorkings also as table fowls. I was not able to rear many early chickens, in consequence of the difficulty of procuring sitting hens, but I had my first batch out in the middle of April, and was very successful through the season, scarcely losing any. I reared about fifty chickens, but, I am sorry to say, the majority were cocks. This gave me a chance of trying their merits as table fowls. I fed them well, and gave them every opportunity of foraging, which they perform assiduously, and was pleased to see their speedy development. I commenced killing some of the earliest hatched at about twelve or fourteen weeks old; they then weighed about 4 lbs. after being put up a week or so to fatten, but at five months we killed them at 7 lbs. On Michaelmas day we sat down to a splendid bird, weighing when trussed $8\frac{1}{2}$ lbs., it had been up about twelve days to fatten.

The flesh is beautifully white, very juicy, and short-grained. I did not kill any pullets, but weighed them very frequently at 5 and 7 lbs. They commenced laying, some at five months and others at six, and are still continuing to give abundance of eggs. I had a good opportunity of judging of the hardiness of the chickens, as, my place being pulled up for drainage, the engine pumping water all day kept the yard constantly wet, but this did not seem to affect them, whereas, if they had been Spanish, Dorking, Hamburgh, or other varieties, they would not have survived.

I think it will be a great pity if these birds are to be made a bird of feather against size and other more sterling qualities. I trust you will pardon this lengthy account, but I think if all our amateurs would make known their failures and successes through the pages of your Journal, which you so kindly throw open to discussion, the fancy would gain a vast amount of information derived from experience and observation.—W. G.

BIRMINGHAM POULTRY SHOW.

SUBJOINED is a list of the principal prizetakers at this important Exhibition, which was opened to the public yesterday, and will continue open till Thursday the 3rd inst. A list of the commended pens, together with a full report, will be given in our next issue.

DORKING (Coloured).—First, Capt. W. Hornby, R.N., Knowsley Cottage, Prescott. Second, Right Hon. Viscountess Homesdale, Linton Park, Staplehurst, Kent. Third, J. D. Hewson, M.D., Coton Hill, Stafford. Fourth, J. Drewry, Newton Mount, Burton-upon-Trent. Fifth Mrs. F. Blair, Balthayock, Inchmartine, Inchture, N.B. (Silver Grey). **Chickens.**—First, Capt. W. Hornby, R.N. Second, A. Potts, Hoole Hall, Chester. Third, Rt. Hon. Viscountess Homesdale. Fourth, Lady Sophia Des Vaux, Drakelow Hall, Burton-upon-Trent. 5th, Mrs. F. Blair.

DORKING HENS.—First, W. Copple, Prescott. Second and Third, Right Hon. Viscountess Homesdale, Linton Park, Kent. **Pullets.**—First and Third, W. Dolby, Rotherfield, Tunbridge Wells (Coloured). Second, Mrs. F. Blair.

DORKINGS (White).—First, Mrs. H. Fookes, Whitechurch, Blandford. Second, H. Lingwood, Needham Market, Suffolk. **Chickens.**—First, H. Lingwood. Second, C. Pease, Southend, Darlington.

SPANISH.—First, H. Lane, Milk Street, Bristol. Second, R. Teebay, Fulwood, near Preston, Lancashire. Third, W. Cannan, Adolphus Works, Bradford, Yorkshire. Fourth, Right Hon. Viscountess Homesdale, Linton Park, Kent. **Chickens.**—First, H. Lane. Second, J. R. Kibbard, Aldwick Court, Wroughton, near Bristol. Third, R. Teebay, Fulwood, near Preston. Fourth, Right Hon. Viscountess Homesdale.

SPANISH HENS.—First, J. Biggar, Marefair, Northampton. Second, R. Teebay, Fulwood, near Preston, Lancashire. **Pullets.**—First, H. Lane, Milk Street, Bristol. Second, J. K. Fowler, Prebendal Farm, Aylesbury.

COCHIN-CHINA (Cinnamon and Buff).—First and Second, Capt. Heaton, Lower Broughton, Manchester. Third, G. Fell, Warrington. **Chickens.**—First, Cup, and Second, Capt. Heaton. Third, T. Boucher, Bull Street, Birmingham.

COCHIN-CHINA HENS (Cinnamon and Buff).—First, E. Smith, Middleton, near Manchester. Second, H. Bates, Harborne Heath Cottage, Birmingham. **Pullets.**—First, C. T. Bishop, Lenton, Nottingham. Second, Capt. Heaton, Lower Broughton, Manchester.

COCHIN-CHINA (Brown and Partridge-feathered).—First, T. Stretch, Ormskirk. Second, Mrs. White, Broomhall Park, Sheffield. Third, Mr. Cartwright, Oswestry. **Chickens.**—First, E. Tudman, Ash Grove, Whitechurch, Shropshire. Second, T. Stretch, Ormskirk. Third, J. K. Fowler, Prebendal Farm, Aylesbury.

COCHIN-CHINA HENS (Brown and Partridge-feathered).—First, Captain. Heaton, Lower Broughton, Manchester. Second, E. Tudman, Ash Grove Whitechurch, Shropshire. **Chickens.**—First, Cartwright, Oswestry. Second, Capt. Heaton.

COCHIN-CHINA (White).—First, R. Chase, Tindal Street, Balsall Heath, Birmingham. Second, W. Dawson, Hopton Miffield, Yorkshire. **Chickens.**—First, G. Lamb, Compton, near Wolverhampton. Second, Master R. W. Chase, Balsall Heath, Birmingham.

BRAMHA POOTRA.—First, Mrs. F. Blair, Balthayock, Inchmartine, Inchture, N.B. Second, R. Teebay, Fulwood, near Preston. **Chickens.**—First, Mrs. F. Blair. Second, Mrs. Rothery, Denbigh House, Haslemere, Surrey.

MALAY.—First, N. Sykes, jun., Globe Road, Mile End, London. Second, Master C. A. Ballance, Mount Terrace, Taunton. **Chickens.**—First and Second, N. Sykes, jun.

CHICK-CHICK.—First, Messrs. Harrison & Caton, Central Beach, Blackpool. Second, S. Waters, Woodbridge Road, Ipswich. **Chickens.**—First, Messrs. Harrison & Caton. Second, Hon. G. E. de Flahault, Tullyallen, Kincardine, on Forth by Stirling, N.B.

HAMBURGH (Black).—First, S. Shaw, Stainland, Halifax. Second, J. Roys, Beaishaw Clough, Middleton, near Manchester. **Chickens.**—First, J. Roys. Second, G. Lingard, jun., Snow Hill, Birmingham.

HAMBURGH (Golden-pencilled).—First, J. Neville, Haseclour Hall, Tamworth. Second, H. Beldon, Gilstead, Bingley, Yorkshire. Third, J. Dixon, North Park, Clayton, Bradford. **Chickens.**—First, H. Beldon. Second, J. Munn, Shawclough, Newchurch, near Manchester. Third, W. Hargreaves, New Church Road, Bacup, near Manchester.

HAMBURGH (Silver-pencilled).—First, J. Keable, Thatcham, Newbury, Berkshire. Second, D. Harding, Middlewich, Cheshire. Third, Rt. Hon. Viscountess Homesdale, Linton Park. **Chickens.**—First, H. Marshall, Cotgrave, near Nottingham. Second, J. G. Sugden, Eastwood House, near Leighley. Third, C. M. Roys, Greenhill, Rochdale.

HAMBURGH HENS (Pencilled).—First, J. Munn, Shawclough, Newchurch, near Manchester. Second, H. Beldon, Gilstead, Bingley, Yorkshire. **Pullets.**—First, J. Munn. Second, J. Robinson, Vale House, Garstang.

HAMBURGH (Golden-spangled).—First, N. Marlor, Denton, near Manchester. Second, J. Robinson, Vale House, near Garstang. Third, S. H. Hyde, Taunton Hall, Ashton-under-Lyne. **Chickens.**—First, W. Kershaw, Heywood, near Manchester. Second, S. H. Hyde. Third, N. Marlor.

HAMBURGH (Silver-spangled).—First, J. Dixon, North Park, Clayton, Bradford. Second, W. Cannan, Adolphus Works, Bradford. Third, Mrs. Pettat, Ashe Rectory, Basinstoke. **Chickens.**—First, Sir St. G. Gore, Bart., Hopton Hall, Wirksworth, Derbyshire. Second, J. Fielding, Newchurch, near Manchester. Third, J. Dixon.

HAMBURGH HENS (Spangled).—First, J. Dixon, North Park, Clayton, Bradford. Second, S. H. Hyde, Taunton Hall, Ashton-under-Lyne. **Pullets.**—First, I. Davies, Bull Street, Harborne, near Birmingham (Golden). Second, S. Shaw, Stainland, Halifax (Silver).

POLISH (Black, with White Crests).—First, T. P. Edwards, Lyndhurst, Hampshire. Second, H. Carter, Upper Thoug, Holmthirp, Yorkshire. Third, J. Dixon, North Park, Clayton, Bradford. **Chickens.**—First, J. Smith, West Lane, Keighley. Second and Third, T. P. Edwards.

POLISH (Golden).—First, H. Snowden, 2, Cliffe Lane, Horton, near Bradford, Yorkshire. Second and Third, J. Dixon, North Park, Clayton, Bradford. **Chickens.**—First, Mrs. Pettat, Ashe Rectory, Basinstoke. Second and Third, J. Dixon, North Park, Clayton, Bradford.

POLISH (Silver).—First and Second, G. C. Adkins, The Lightwoods, near Birmingham. Third, J. Dixon, North Park, Clayton, Bradford. **Chickens.**—First and Second, G. C. Adkins. Third, J. Dixon.

ANY OTHER DISTINCT VARIETY.—First, Right Hon. Lord Guernsey, The Bury, near Leamington (Cuckoo Dorkings). Second, J. L. Lowndes, Hartwell, Aylesbury (Andalusian). Third, Right Hon. the Countess of Aylesford, The Bury, near Leamington Spa (Cuckoo Dorking).

GAME (Black-breasted Reds).—First, J. H. Williams, Spring Bank, near Welsh Pool. Second, J. Doncaster, North Hykeham, Lincolnshire. Third, H. M. Julian, Beverley. Fourth, J. Fletcher, Stoneclough, near Manchester. **Chickens.**—First, Rev. G. S. Crawys, Crawys Moorhead, Tiverton. Second, C. Stubbs, Preston Hill, Peakridge. Third, J. Stubbs, Weston Hall, Stafford. Fourth, W. H. Swann, Farnfield, Southwell.

GAME (Brown and other Reds, except Black-breasted).—First, A. B. Dyas, Shropshire. Second, J. Doncaster, North Hykeham, Lincoln. Third, T. Robinson, Poplar Grove, Ulverston. Fourth, J. Fletcher, Stoneclough, near Manchester. **Chickens.**—Cup, First and Second, J. Wood, Moat House, Wigan. Third, H. Adams, Yorkshire. Fourth, M. Billing, jun., Birmingham.

GAME HENS (Black-breasted and other Reds).—First, M. Billing, jun., Birmingham. Second, T. Carless, Nottingham (Brown Red). **Pullets.**—First, W. H. Swann, Farnfield. Second, M. Billing, jun.

GAME (Ducklings and other Greys and Blues).—First, J. Garlick, Liverpool. Second, H. Adams, Yorkshire. Third, T. Carless, Hoveringham. Fourth, J. Fletcher, Stoneclough. **Chickens.**—First, J. Fletcher. Second, T. Carless, Hoveringham. Third, J. Holme, Prescott. Fourth, W. Pares.

GAME (Blacks and Brassy-winged, except Greys).—First, J. Fletcher, Stoneclough, near Manchester. Second, G. W. Dawson, Rockley, Birmingham. Third, Rev. G. S. Cruwys, Cruwys Morchard, Tiverton. *Chickens*.—First, J. Fletcher. Second and Third, G. W. Dawson.

GAME (White and Piles).—First, J. Fletcher, Stoneclough (Pile). Second, H. Adams, Beverley, Yorkshire. Third, A. Guy, Eaton, Grantham. *Chickens*.—First, H. Adams. Second, T. Whittaker, Melton Mowbray (Pile). Third, T. Fletcher, Great Malvern (White).

GAME HENS (except Black-breasted and other Reds).—First, J. Goodwin, jun., Everton, Liverpool (Duckwing). Second, F. Lythall, Spittall Farm, near Banbury (White). *Turkeys*.—First Miss K. Charlton, Manningham, Bradford, Yorkshire (Duckwing). Second, A. Guy, Eaton, Grantham (Pile).

CLASSES FOR SINGLE COCKS.

DONKING.—First, Viscountess Holmesdale, Linton Park. Second, H. Lingwood, Suffolk. Third, Mrs. Arkwright, Derby. Fourth, W. W. Bartlam, Henly-in-Arden.

SPANISH.—First, Viscountess Holmesdale, Linton Park. Second, H. Lane, Bristol. Third, R. Tebbey, Preston.

COCHIN-CHINA (Cinnamon and Buff).—First, R. White, Broomhall Park, Sheffield. Second, G. Fell, Warrington. Third, Mrs. Wolferstan.

COCHIN-CHINA (Except Cinnamon and Buff).—First, R. White, Sheffield (Partridge). Second, T. Stretch, Grimsby. Third, J. Shorthose.

BAHAMA POOTRA.—First and Second, Mrs. Feignsson Blair.

HAMBURGH (Golden-necked).—First, W. Kershaw, Heywood, Manchester. Second, J. Munn, Manchester.

HAMBURGH (Silver-necked).—First, J. Robinson, Garstang. Second, C. M. Roids, Rochdale.

HAMBURGH (Golden-spangled).—First, N. Marlow, Denton, near Manchester. Second, W. Kershaw, Heywood, near Manchester.

HAMBURGH (Silver-spangled).—First, Right Hon. Viscountess Holmesdale, Linton Park, Kent. Second, J. Fielding, Newchurch, near Manchester.

TULISH.—First, J. Smith, West Lane, Keighley. Second, J. Dixon, North Park, Clayton, Bradford.

GAME (White and Piles, Duckwings and other varieties, except Reds).—First, H. Adams, Beverley. Second, J. H. Williams, Spring Bank, Welshpool (Duckwing Grey). Third, C. B. Lowe, Sheep Hall, Atherstone (Silver Duckwing). Fourth, S. Matthew, Chilton Farm, Stowmarket (Duckwing).

GAME (Black-breasted Reds).—First, J. Stubbs, Weston Hall, Salford. Second, J. H. Williams, Spring Bank, near Welshpool. Third, E. C. Gilbert, Penkridge. Fourth, J. J. Cranidge, Crowle, Lincolnshire. (Remarkably good class.)

GAME (Brown and other Reds, except Black-breasted).—First, T. Statter, Stand Hall, Pilkington, Manchester. Second, M. Billing, jun., Gravelly Hill, near Birmingham. Third and Fourth, J. Fletcher, Stoneclough.

BANTAMS (Gold-laced).—First and Third, M. Leno, jun., the Pheasantry, Markyate Street, near Dunstable. Second, T. H. D. Bayly, Ickwell House.

BANTAMS (Silver-laced).—First and Second, T. H. D. Bayly, Ickwell House, near Biggleswade. Third, M. Leno, jun., the Pheasantry, Markyate Street, near Dunstable.

BANTAMS (White, clean-legged).—First, H. E. Emberlin, Leicester. Second, J. Dixon, North Park, Clayton, Bradford. Third, Miss K. Charlton, Manningham, Bradford, Yorkshire.

BANTAMS (Black, clean-legged).—First, J. Ludlow, Solihull, near Birmingham. Second, Miss K. Charlton, Bradford, Yorkshire. Third, Rev. G. S. Cruwys, Tiverton.

BANTAMS (Any other variety, except Game).—First, J. D. Newsome, Batley, Yorkshire (Cochin-China, Buff and Cinnamon). Second, Mrs. H. Fookes, Blandford (Japanese). Third, Master K. W. Chase, Birmingham (Japanese).

GAME BANTAMS (Black-breasted and other Reds).—First, T. H. D. Bayly, Ickwell House, near Biggleswade. Second, Sir St. G. Gore, Hopton Hall, Wirsbrough, Derbyshire. Third, Capt. Wetherall, Loddington.

GAME BANTAMS (Any other variety).—First, B. Hawkesley, jun., Southwell. Second, W. Silvester, Hampden View, Sheffield (Duckwing). Third, Miss E. Crawford, Farnfield, Southwell (Duckwing).

GAME BANTAM COCKS.—First, J. W. Kelleway, Isle of Wight. Second, Miss E. Crawford, Southwell. Third, R. Hawksley, jun., Southwell.

DUCKS (White Aylesbury).—First, J. Smith, Lincolnshire. Second, Mrs. Seamons, Aylesbury. Third, J. K. Fowler, Aylesbury.

DUCKS (Rouen).—First, H. Worrall, West Derby. Second, T. Statter, Manchester. Third, S. Shaw, Halifax.

DUCKS (Black East Indian).—First, J. R. Jessop, Hull. Second, J. Beasley, Northampton.

DUCKS (Any other variety).—First, T. H. D. Bayly, Biggleswade (Brown Call). Second, J. Dixon, Bradford.

ORNAMENTAL WATER FOWL.—First and Second, C. Baker, Chelsea.

GESE (White).—First, Mrs. Seamons, Hatfield, Aylesbury, Buckinghamshire. Second, W. Kershaw, Heywood, near Manchester. Third, J. K. Fowler, Prebendal Farm, Aylesbury. *Goslings*.—First, J. K. Fowler. Second, D. H. Davies, Mere Old Hall, near Knutsford, Cheshire.

GESE (Grey and Mottled).—First and Third, Miss F. Blair, Balhaycock, Inchmartine, Incheure, N.B. Second, J. K. Fowler, Aylesbury. *Goslings*.—First, W. Dolby, Borsa Grove, Rothenfield, Tunbridge Wells (Toulouse). Second, Mrs. F. Blair. Third, R. W. Boyle, Rosemount, Dundrum, county Dublin (Toulouse).

TURKEYS.—First, Mrs. A. Guy, Eaton, near Grantham (Cambridgeshire). Second, Mrs. F. Blair, Balhaycock, Inchmartine, Incheure, N.B. (Cambridgeshire). Third, Mrs. Guy (Cambridgeshire). *Poult*.—First, J. Smith, Breder Hills, near Grantham, Lincolnshire (Cambridgeshire). Second, Mrs. A. Guy (Cambridgeshire). Third, J. W. Smith, Oundle (Cambridgeshire).

PIGEONS.

ALMOND TUMBLERS.—First, F. Else, Bayswater, London. Second, P. Eden, Salford. Third, M. Stuart, Glasgow.

CARRIER COCK (Black).—First and Second, P. Eden, Salford. (A good class.)

CARRIER COCK (Any other colour).—First, P. Eden, Salford (Dun). Second, T. Colley, Sheffield (Dun).

CARRIER HEN (Black).—First, Messrs. W. Siddons & Sons, Aston, near Birmingham. Second, F. Else, Bayswater, London.

CARRIER HEN (Any other colour).—First, P. Eden, Salford (Dun). Second, T. Colley, Sheffield (Dun).

POWER COCK (Red or Blue).—First and Second, R. Fulton, Deptford.

POWER COCK (Any other colour).—First, P. Eden, Salford. Second, R. Fulton, Deptford.

POWER HEN (Red or Blue).—First, P. Eden, Salford. Second, G. R. Potts, Sunderland.

POWER HEN (Any other colour).—First, R. Fulton, Deptford. Second, P. Eden, Salford.

RAIS.—First, F. Esquilant, Oxford Street, London (Blue). Second, J. W. Edge, Birmingham.

RAIS.—First, W. H. C. Oates, Newark, Notts. Second, F. Else, Bayswater, London (Blue).

MOTTLED TUMBLERS.—First, P. Eden, Salford. Second, W. H. C. Oates, Newark, Notts.

TUMBLERS (Any other colour).—First, J. Fielding jun., Yorkshire Street, Rochdale (Short-faced Yellow Agate).—Second, H. Morris, Forest Hill, Kent (Self).

RUETS.—First and Second, D. T. Green, Saffron Walden, Essex (Spanish). *JACOBINS* (Red or Yellow).—First, J. T. Lawrence, Everton, Liverpool. Second, F. Esquilant, Oxford Street, London. (Very good class.)

JACOBINS (Any other colour).—First, J. T. Lawrence, Everton, Liverpool. Second, F. Else, Bayswater, London.

FANTAILS (White).—First and Second, H. Yardley, Market Hall, Birmingham. (Good class.)

FANTAILS (Any other colour).—First, F. H. Paget, Birstall, Leicestershire. Second, J. W. Edge, Aston New Town, Birmingham.

TRUMPETERS (Mottled).—First, S. Shaw, Stainland, Halifax. Second, F. Else, Westbourne Grove, Bayswater, London. (Good class.)

TRUMPETERS (Any other colour).—First, W. H. C. Oates, Bosthorpe, Newark, Nottinghamshire (White). Second, S. Shaw, Stainland, Halifax (Black). (Excellent class.)

OWLS (Blue or Silver).—First, J. Fielding, jun., Yorkshire Street, Rochdale. Second, F. Else, Westbourne Grove, Bayswater, London.

OWLS (Any other colour).—First, W. Sanday, Holme Pierrepont, Nottingham (White). Second, J. Baily, jun., Mount Street, London, W. (Imported).

NUSS.—First, F. Else, Westbourne Grove, Bayswater, London. Second, J. Choyce, jun., Harris Bridge, Atherstone.

TURBIS (Red or Blue).—First, S. Shaw, Stainland, Halifax. Second, J. W. Edge, Aston New Town, Birmingham.

TURBIS (Any other colour).—First, S. Shaw, Stainland, Halifax (Yellow). Second, J. Percival, Montpellier Road, Rye Lane, Peckham, London.

RAIS (Black).—First, P. Eden, Cross Lane, Salford. Second, W. Sanday, Holme Pierrepont, Nottingham.

RAIS (Any other colour).—First, P. Eden, Cross Lane, Salford (Yellow). Second, M. Stuart, Waterloo Street, Glasgow.

DRAGONS.—First, J. Percival, Montpellier Road, Rye Lane, Peckham, London. Second and Third, F. Esquilant, Oxford Street, London.

MAGPIES.—First, F. Else, Westbourne Grove, Bayswater, London. Second, J. Percival, Montpellier Road, Rye Lane, Peckham, London.

ANTWEERS.—First and Second, H. Yardley, Market Hall, Birmingham.

ANY OTHER NEW OR DISTINCT VARIETY.—First, H. Yardley, Market Hall, Birmingham (Sautettes). Second, Rev. C. Spencer, College House, Attleborough, Norfolk (Swiss). Third, G. H. Sanday, Holme Pierrepont, Nottingham (Black-tailed Owls).

"EGOMET." ADVERTISEMENTS, &c.

"EGOMET" (see JOURNAL OF HORTICULTURE, November 17th, page 401), expressed my own opinions and feelings so very exactly, that I felt inclined to construe this compound pronoun as I did at school, "I myself."

I have always found poultry-fanciers a very genial brotherhood—aye, and sisterhood, too, for we must not forget that among the latter are many of the most successful exhibitors, and what, perhaps, is of more importance, the best understanders of the domestic feathered tribes: so that I think a plan might be possible and feasible among them, which would be neither possible nor feasible among fanciers of some other things, horses for example, for the touch of horseflesh seems to interfere sadly with common honesty. Hence to my notion "AN EXHIBITOR IN A SMALL WAY" propounds a good scheme, which "EGOMET" endorses, but which the Editors of this Journal could alone decisively tell us whether or not it could be successfully carried out; the said scheme being "to set apart a column of this paper in which subscribers could notify their wants as to buying, selling, and exchanging, without the formality of an advertisement." Of course, this must be for amateurs only. Next, I will give my reasons. Advertisements are by many persons greatly distrusted. Incumbents advertise for curates: "Ah!" exclaim some people, "can't get on with the poor young men, always changing, jealous, &c." Curates advertising: "Ah! lazy fellows, been everywhere, and liked nowhere." Horses advertised for sale. "Ah! screws." Well, without doubt, although good things are to be had through advertisements, yet there is a great prejudice against them, and purchasers do sometimes get woefully deceived. Then, again, suppose we fanciers apply to bird-dealers, what then? I, an old Pigeon-fancier, have had very mature Dragons sent me for Carriers, and have just missed having had sent me—missed by taking a journey to see them—Game Bantams with feathered legs, or rather with a plentiful crop of feathers on their legs. Quite recently a friend of mine

in passing a bird shop in a large town, saw a pair of good Barbs in a cage outside; being in want of such Pigeons, he stopped and inquired the price—that was not out of the way—"but are they a pair?" "Yes, Sir." "Well, I am an old Pigeon-fancier, and I live in the neighbourhood, and I think they are two cocks." "Well, Sir, as you are an old Pigeon-fancier, and as you live in the neighbourhood (hope of future custom arising), I confess they are two cocks."

But I may have it said in reply to my advocacy of this plan, which has already found favour with two writers in your Journal, there are honourable dealers: Mr. Baily, for instance, would never deceive you. Granted at once in Mr. Baily's case, but the price! and I own I dare not have dealings with men in business, unless I can see my birds.

As a further reason, I will give my own case, a similar one to that of many. Of recent years I have been a breeder of black Bantams, and had (for death, alas! has thinned them), some as good pullets as I have ever seen; then, lo! my best cock dies, and where am I to get another? Or, I have birds to spare, and no fancier living near me; I take them into Bath, and have a magnanimous offer at a dealer's of eighteenpence a-head! Of course, at such a price I will not sell them, so with regret I kill them, whereas another poultry-fancier might just want what I have too many of, and be wondering where on earth he could buy them.

Such a special column as suggested by your correspondent, "AN EXHIBITOR IN A SMALL WAY," and approved by "EGOMET," would meet the difficulty; open solely, remember, to your subscribers, and to no dealer on any pretence whatsoever. As to being an unfair act in regard to tradesmen, I would reply, We amateurs are driven to it in self-defence, for either prices are absurdly high, or there is a pleasant prospect of deception before us. All that "EGOMET" says about fairness at exhibitions I readily endorse. Mistakes there may and must be occasionally. If there be known unfairness, the press is open. As to Judges, procure known good ones, and trust to their judgment. I may differ here and there from them, "many men many minds," but when acting as Judges I abide by their decision.

Well said, "EGOMET," about Christmas-day. Let nothing break the circles gathered round the hearth on that day, replete with kindness and good will to and among men.

I also agree with "EGOMET" as to a list of the pens sold, their prices, &c., being printed at the end of the prize lists. This could easily be done. The great point is to increase and make easier the means of mutual assistance among the poultry brotherhood; and, rely upon it, this will also increase the love of poultry—in fact, add to the brotherhood. When people see others reap pleasure from a pursuit, and the many difficulties as to procuring birds, &c., done away with, they will wish to try their hands. Prejudice arises from ignorance, pleasure comes with knowledge.

I have throughout this paper gone upon this supposition, that all lovers of poultry are fair and honest, as upon this being the case the success of the plan would wholly depend. —WILTSHIRE RECTOR.

CHIPPENHAM POULTRY SHOW.

The following is a list of the awards at the Show recently held:—

DORKINGS.—First, E. Hedges, Chilton. Second, F. Bailey, Calne. Highly Commended, T. R. Hulbert, Cirencester.
SPANISH.—Prize, A. Heath, Calne.
GAME (Black-breasted and other Reds).—First, H. Waller, Calne. Second, H. Stevenson, Landsend, Chippenham. Highly Commended, J. Orlidge, Chippenham. Commended, T. R. Hulbert, Cirencester.
GAME (Any other variety).—First, J. Muspratt, Heytesbury. Second, J. Goulter, Acton Turnville.
COCHIN-CHINA (Any variety).—First, Miss J. Milward, Newton St. Loe. Second, H. Witchell, Tetbury.
HAMPTONS (Golden-pencilled).—First, H. Witchell, Tetbury. Second, J. S. Maggs, Tetbury.
HAMPTONS (Silver-pencilled).—First, J. W. W. Hulbert, Chippenham. Second, G. S. Sainsbury, Devizes.
HAMPTONS (Golden-spangled).—First, J. S. Maggs, Tetbury. Second, Mrs. Marston, Bishopstrow.
POLANDS (Any variety).—First, J. Phillips, Chippenham. Second, J. Hinton, Hinton.
ANY OTHER DISTINCT OR CROSS BREED.—First, J. Hinton, Hinton. Second, J. J. Fox, Devizes.
BANTAMS (Game).—First, F. Bailey, Calne. Second, F. H. Phillips, Chippenham.
BANTAMS (Any other variety).—First, J. J. Fox, Devizes. Second, E. Cambridge, Bristol.

TURKEYS.—First, W. Hower, Sevenhampton. Second, Miss J. Milward, Newton St. Loe.

GESE.—First, G. Hanks, Quobwell. Second, R. P. Rich, Chippenham. Highly Commended, Mrs. A. P. Smith, Beversbrook; — Coleman, Beversbrook.

DUCKS (Aylesbury).—First, G. Hanks, Quobwell. Second, Mrs. A. P. Smith, Beversbrook.

DUCKS (Rouen).—First, J. W. Brown, Uffcott. Second, Mrs. Kent, Newton.

DUCKS (Any other variety).—First, Miss J. Milward, Newton St. Loe. Second, — Coleman, Beversbrook.

SWEETSTAKES (Game Cock).—Prize, A. Heath, Calne. Highly Commended, F. Bailey, Calne.

JUDGE.—Mr. J. R. Rodbard, Wrington, near Bristol.

NEW VARIETIES OF PIGEONS.

I HAVE to offer my thanks to Mr. Alfred Heath, for his kindness in replying to my request for a description of that variety of tame Pigeons that has recently been exhibited as Isabel Pigeons. From his writing I recognise them as Dutch Powters. Gottlob Neumeister, in his German work on Pigeons, says they are of various colours, as black, blue, red, yellow, isabellenfarbig (buff-coloured), and white; frequently with white wing-bars on the isabellen, blue, and red, but he has never seen white wing-bars on the black. I remember seeing a pair at the Crystal Palace which most likely were Mr. Heath's, and they exactly resembled Herr Gottlob Neumeister's plate of the Isabellenfarbigen Holländische Kropftaube. They should, therefore, be called Isabel Powters, and not Isabel Pigeons, as the word Isabel refers only to their colour, and not to the breed.

I should also be obliged by a description of those Pigeons shown as Satinets and Neapolitans, as both these names have appeared in catalogues of recent Pigeon shows; and as I am not acquainted with the breeds, at least by those names, I ask some breeder of them for full particulars of their origin, peculiar points, colour, &c.

May I beg of any Pigeon-fancier, or reader of THE JOURNAL OF HORTICULTURE, who is acquainted with the Lowtan or Ground Tumblers of India, to send a description of them? Also, if any one can tell what variety of Pigeons it is that the natives of India train for high flying. Are they like any of our high-flying breeds of Tumblers? I have myself a wonderful Tumbling breed of Pigeons, many of which while flying throw from fifteen to thirty summersaults in a minute; some of them roll till they touch the ground, and a few can hardly fly from excessive tumbling. Thus taking an interest in Tumbler Pigeons, I should be greatly obliged for any account of the Indian, or any other new variety. As to the reason of a Pigeon's turning over while flying, I may refer to that at some future time.—B. P. BRENT.

SINGULAR DEPOSIT ON A HIVE FLOOR.

A NEW MATERIAL FOR HIVES—FOUL BROOD.

WELL acquainted as I have long been with the very large accumulation of filth of all kinds too frequently to be seen on the slates of the cottager's hives, yet I certainly was not prepared for what lately met my view upon lifting a hive from its stand, revealing as it did a most extraordinary accumulation of a jelly-like substance, covering the whole of the slate, to the depth of three-eighths of an inch, and which when removed would have filled a large breakfast-cup. It was not merely a cursory glance I had of this singular substance, for, having transferred the hive to a clean slate, I was enabled to examine it at my leisure. What makes it the more remarkable is, that the hive was a new one, tenanted by a swarm of the present season, the combs clean, and the bees healthy, the slate, also, being a new one from a quarry close by. The owners of the hive thinking I might be an intending purchaser, expressed no surprise when I called their attention to the state of the slate, remarking, they always found lots of dirt, but upon close examination they also expressed great surprise, never having seen anything like it before. It struck me at first there must have been a quantity of moist sugar introduced into the hive; but I found it had not been lifted since it was tenanted by the swarm. I can compare it to nothing but calves'-foot jelly, having the same motion when shaken, and resisting the touch with the same degree of elasticity. A few bees only were clogged and help-

less on the surface; there being no other dirt, and very little odour proceeding from it. I can only suggest that it may have been the spawn of some creature, but the extraordinary quantity makes it more surprising and difficult to account for. One portion somewhat more fluid than the rest contained a dozen or more flattish white maggots slowly moving about, quite different from any I remember to have previously observed. I should much wish to know whether any one else has met with this appearance, for I have lifted so many hives without observing even the slightest trace of a similar substance, that it strikes me as being something very remarkable.

I have been experimenting upon a new material for the construction of hives, which I think likely to prove most excellent, so that I am sanguine as to great results accruing from its use. This material is tan, in the compressed state in which it is used for fuel in our neighbourhood. It is free from smell, and will form a hive in which the interior temperature will be very equable. I compress the moist tan into moulds, thus forming the walls of the hive, and the top and bottom slabs, the latter about 3 inches, and the former 5 inches in thickness. Ledges in the front and back take bars as in the ordinary boxes. This material is capable of being moulded into any shape—square, octagon, or circular, with tops flat or dome-shaped like the common straw hive. It takes long drying, but does not absorb moisture or damp subsequently. The material for an eight-bar hive costs little more than a shilling. The cheapness of the material is, therefore, one recommendation. It will have a very pretty effect in the garden. A slate on the top will keep off all wet.

My Ligurian stock, procured from Mr. Woodbury in the spring of 1862, has succumbed to that fearful scourge, "foul brood." Although I gave the bees a new hive of wholesome combs, they dwindled away to some few scores in numbers, and within the last few days an unsuccessful attempt to unite their queen (which, moreover, was a poor, dark little thing) to another hive, which I had rendered queenless, and with every precaution as to her welfare, has now left me in a condition to trust entirely to my common bees; and whether I may renew my acquaintance with the Italians is doubtful, as from what I have seen of the honey-gathering powers of the Ligurians, I fancy they are little, if at all, superior to the little black fellows.—Geo. Fox, *Kingsbridge, Devon*.

FOUL BROOD.

"My thoughts, I must confess, are turned on peace."

So spoke a Roman senator in olden times, and so in substance spake recently in the columns of this Journal "A HAMPSHIRE BEE-KEEPER," who, raising the standard of peace in this apian controversy, has invited all to follow him. As for myself, my voice must be for peace; but before quitting this profitless interlude in our discussion, it behoves me to add a word or two.

In the first place, I shall be spared the disagreeable necessity of replying to "B. & W.'s" warlike article in No. 136, in which he appears to have completely exhausted his fire and fury on my unfortunate "enigmatical," which having belaboured to his heart's content, he exclaims, "Let us hope that we shall now be suffered to return to peace."

Mr. Edwards I shall keep in remembrance when I come to discuss some facts in which he is interested. Meantime let him not vex himself in fruitless efforts to make "the cap fit." If it be actually too tight why not throw it aside at once?

To Mr. Woodbury, what shall I say? I could wish to say less than I must. I cannot, of course, pretend to control his beliefs, to alter his views, or smooth down the asperity of words which I have before refuted; but when these beliefs are assumed as facts to which I am by implication called on to assent, and embodied in his last article in the formula of my confession, I must, in honour, interpose my non-acquiescence, and claim the privilege of abiding by facts as they have already been explained by me, and not as interpreted by others. With these remarks I have done; but as my warfare was directed against principles rather than persons, I can see no barrier whatever to my joining cordially in the general "hum" of harmony set in motion by "A HAMPSHIRE BEE-KEEPER," whose vocation I have always regarded as the noblest on earth.

SHIRE BEE-KEEPER," whose vocation I have always regarded as the noblest on earth.

In regard to the general question of foul brood and the subsidiary but very important question raised, as to "Whether bees do remove chilled and abortive brood in all stages from the hive," it is my purpose to devote a paper exclusively to its consideration. It will be seen that my views are diametrically opposed to those of Mr. Woodbury, "B. & W.," and Mr. Edwards on this question, and I think it is but due to the interests of apiculture and truth that this subsidiary question should be thoroughly examined into and cleared up. If I shall be able to demonstrate satisfactorily the negative of this proposition—namely, that "bees do not remove chilled and abortive brood in all stages from a hive," which I think I can, then I shall pave the way, I hope, for a general acquiescence in the doctrines which—in opposition to the most skilled apiarians of the day, both home and foreign, in reference to the nature and origin of foul brood—I have had the temerity to propound in these pages. This at present is a promise. The fulfilment anon.

Meantime I hail as a good omen (for "coming events," it is said, "cast their shadows before"), some faint indications in Mr. Woodbury's last paper of a little wavering. I imagine, in his views on this very point. Some revelations from "the north" have apparently wrought this change. But be this as it may, we must all, as true students of Nature, search after truth in the love of it; and while probing Nature herself to give forth "her answers," may we, as the Editors reminded us in a recent Number, accept these as from an unfailing oracle. "Great is truth and it will prevail." *Magna est veritas, et prevalebit*.—J. Lowe.

OUR LETTER BOX.

POULTRY CHRONICLE (Poultry-Keeper).—There is no separate publication now with that title. It was amalgamated with this Journal some years ago.

DISEASED POULTRY—CASE OF GAPES (L. R.).—We fancy it is the gapes, but we have never seen birds die fast when they are thus affected. The "stretching of necks and gaping" describe the symptoms exactly. Of all the remedies we have tried, and their name is Legion, we know but one effectual. We have tried it only this year, and with great success. It is easy to administer either by putting a piece as large as a pea down the throat, or by keeping a lump always in the water. It is camphor.

FOOD FOR POULTRY (J. M. C.).—Barley is unquestionably a better food for poultry than Indian corn, and, as a rule, it is the cheapest. But the small birds eat so much of it that recourse must be had to Indian corn—two-thirds barley, one-third Indian corn. In very cold weather we shall feed on the latter entirely, to avoid nourishing the myriads of sparrows, greenfinches, chaffinches, yellow-hammers, and all the other fitches and hammers.

POLANOS AT THE NORFOLK SHOW (F. H. P.).—We have not the prospectus of the Society's show, but it probably contained the usual rule, that the Judges may withhold prizes if they deem the birds undeserving of an award. The Judges may be wrong in their decision, but no Committee would reverse their decision unless a case was made out showing improper influences. It was not courteous on the part of the Secretary to refrain from answering your letter.

SEBASTOPOL GEESSE, &c. (Wear Valley).—Full information has been given in our back Numbers on all these subjects. We know no book devoted to them. They will all bear our winter as well as any of our own birds. We have Carolinas and Californian Quails exposed to all weathers, now and for more than a year, with no other shelter than a pent roof 5 feet from the ground at the lowest part. We had Sebastopol Geese out of doors all last winter. A swimming place is not necessary for the Geese, but it is for the Ducks. It need not be large at this season of the year. In the early spring, indeed soon after Christmas, a swimming place is absolutely necessary for the Geese as well as Ducks. They will not breed without it. The diet of the Geese will be barley; of the Carolinas, barley varied at times with a little hempseed; of the Californians, oats, barley, and bread. All require a plentiful supply of grass or other green meat, and the Quails will not live without it.

ILLUSTRATED POULTRY BOOK (Herberta).—The "Poultry Book" is the best illustrated book we know. Bantams and Cochins-Chinas may be kept together, but no other small fowls. There is all the difference in life between a Bantam and a small fowl. Cochins-Chinas will do well in such a place as you describe; but they will not perch on trees: it is not their nature. A very small and low house will answer every purpose for their roosting place. It will not be unsightly, and the fowls will breed prize stock if they are good enough.

FEEDING BEES (T. R. D.).—Six pounds of lump sugar to one pint of water is about four times the proper quantity. We put three pounds of sugar to two pounds of water, and boil the syrup a minute or two.

WATER IN LEAD CISTERN (Oxide of Lead).—Water so kept is always injurious, more or less, to those who drink it. The intensity of the injury depends upon the purity of the water—the purer it is the more rapidly it acts on the lead. The usual symptoms are costiveness, tenderness over the stomach when pressed upon, nausea, and vomiting.

FEASING CALVES (F. S. Allen).—You can have No. 62 of this series of our Journal if you enclose four postage stamps, with your address. In that is a long extract giving good directions, and too long to reprint.

WEEKLY CALENDAR.

Day of M th	Day of Week.	DECEMBER 8-14, 1863.	Average Temperature near London.			Rain in last 36 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 46.0°, and its night temperature 33.7°. The greatest heat was 61°, on the 13th, 1842; and the lowest cold, 11°, on the 13th, 1846. The greatest fall of rain was 0.62 inch.

POT-CULTURE OF PEACHES AND OTHER FRUITS, VERSUS THE PLANTING-OUT SYSTEM.

ALTHOUGH the cultivation of Peaches and other fruits in pots is not by any means an idea of recent origin, it is only within the last twelve or fourteen years that it has been extensively practised; and to some extent it has become popular by the erection of houses on a somewhat extensive scale for the express purpose of

growing such fruits in pots. To Mr. Rivers, the intelligent nurseryman of Sawbridgeworth, more than to any other man, the public are indebted for whatever amount of pleasure or profit that has arisen from the system. All who have watched, for the last eight or ten years, Mr. Rivers' almost incessant and rational advocacy of the system, and the dexterous energy with which he has appeared on almost every field to shield it from attack, must have been deeply impressed with the idea that the culture of fruit trees in pots is a system the desirability of which he most earnestly believes, while his own success has been proof sufficient that good fruits can be so produced in abundance. This may be accepted as a fact not to be controverted.

I have never had the pleasure of an ocular demonstration of Mr. Rivers' great success in this particular department, but I have met with gentlemen who have been to the nurseries at Sawbridgeworth, and who have corroborated Mr. Rivers' own statements of his successes. That such fruit can be so produced is a fact which requires neither demonstration nor proof. It is only necessary to go to Sawbridgeworth and several other places where the inspection of the system is kindly permitted to all who are interested in the matter. This is, however, a very different thing from recommending the pot-system in preference to any other. This has generally been carefully avoided, as far as I am aware of, by its most ardent advocates, no doubt because they are convinced that such a one-sided view of the matter would only have provoked the ridicule of all who understand by what means the production of the greatest quantity of first-rate fruit with the least possible outlay of time and expense can be obtained.

The controversial skirmishes on this subject which have come off in the various periodicals have no doubt been productive of much good. They have at the same

time thrown the inexperienced on the horns of a dilemma as to which of the two systems is to be preferred, because no reliable comparisons have been drawn by persons well conversant with both sides of the question. I have sometimes had to advise in this matter, and always in favour of planting out and training to a flat surface in the usual way. There is, however, no particular fault to find with any one who chooses to recommend the pot-system, for I would like to see the plant or fruit that an English gardener could not make productive and interesting in a pot; and those who grow their own fruit, and are not responsible for the best possible supply, may grow it as they choose. But the strenuous advocacy of the pot-system as the ideal of perfection by those who probably date their gardening experience from some time between this and the period when orchard-houses have been inaugurated, and who probably have never tried any other system, is amusing enough. Let every system have its full share of merit allowed it, and however desirable the pot-culture of fruit may be considered, the great majority of good gardeners who have to supply the fruit market or their employers' tables with the very best fruit and on the most economical principles, are thoroughly satisfied that their task must be performed with trees planted out in borders and not grown in pots, however well managed the latter may be.

A very interesting article in this Journal, November 24th, from the pen of "T. R.," sets this matter completely at rest, if any doubt ever existed. He balances carefully the comparative merits of the two systems; and the sum total of his deductions is that a fourth more in quantity, and fruit of superior quality, can be produced from trees planted out and trained to trellises. Surely this is a most powerful argument in favour of any system, especially as it will be suspected that it comes from the most powerful advocate of a rival system. The principal argument in favour of trees in pots is that it affords more pleasure than when grown and trained otherwise. Many will venture to suppose that this argument will weigh only with a very small number of growers. No doubt a houseful of trees in pots must be interesting and pretty, yea, lovely; but in most cases the proof of the pudding will be considered to lie in something else.

It would be very interesting to make a comparison of the expense of furnishing an orchard-house in the two different ways, and of the time and labour that are required to bring a crop to maturity, the chances of success or failure, as well as the different other purposes for which, under the two methods, such structures are available.

If the expense of furnishing be first taken into consideration I will refer, for the sake of illustration, to a long lean-to orchard-house which was erected here last year. It is 135 feet long, 11 feet wide, 12 feet high at the back, with a two-feet front light. There were a few very fair Peach trees on the wall before the house was built. The rest of the space has been furnished with dwarf-trained and rider Peaches and Nectarines. But suppose the whole had to be newly furnished with trees,

sixteen trees would be sufficient for the back wall—eight riders and eight dwarfs. Trees can be trained about 7 feet up from the front close to the glass without shading the back wall, and here twelve Peaches and Plums, dwarf-trained trees, in equal proportions, have been planted. Here are eight riders at 10s. 6d. each, and twenty dwarfs at 7s. 6d. each, which amount to a few shillings under £12 for furnishing the house on the planting-out and trellis-training system. First-class trees can be bought at the prices quoted, and I always find that they bear a few fruits the same year they are planted; and some of the riders which I planted last December are now covering more than 50 square feet of surface, so that with them and the dwarfs the wall is almost completely covered.

Suppose that, instead of this lean-to, it were an orchard-house 67½ by 22 feet, it would require about 120 trees in pots to furnish it, which at 5s. amount to £30—a sum sufficient to furnish and heat the house with hot water on the rival system. Perhaps trees in pots could be purchased for less than 5s.; so could the trained trees in the other case, but in both cases they would be less or inferior.

In the lean-to house referred to there is a training surface of more than 2000 square feet fully exposed to the sun, which, the advocates of the pot-system being judges, is the best possible position for producing fine fruit. True, it may be termed an unnatural mode of training the branches, but not more so than that to which the roots are subject in the other case, to say nothing of the incessant pinching to which they are, no doubt, very properly subjected. The house in question is so ventilated that a free current of air can be made to play on every leaf, and when desirable a shower of rain in summer can be allowed to fall on the whole of the back wall. The most extraordinary house of Peaches on this principle which I have ever seen is at Dalkeith Park. The Pears in pots at the same place are, no doubt, fine in their way, but I never heard that any one was astonished with them, while plenty have so expressed themselves with regard to the Peaches, which have been transformed in a few years from a wall of indifferent trees into the style with which plenty are now familiar, and all by a mere covering of glass.

With regard to the labour and attention rendered necessary by these two modes of producing fruit, I would simply appeal to all gardeners who have had any experience in the matter, or who are, from their intimate knowledge of managing any other plants in pots, capable of drawing a pretty correct estimate, and I feel certain they will have no difficulty in deciding in favour of the planting-out system. I would not for a moment detract from the correct impressions which have been conveyed of the pleasures attending the management of fruit trees in pots: far from it. It would, indeed, be difficult to overestimate pleasing hours which might be enjoyed by any who had a fancy for so spending their time and money. But, then, taste is so varied that while one may derive pleasing recreation from watching and tending a Peach tree in a pot, another might reap the same enjoyment from a fruit tree managed in any other way. On the other hand, there is no necessity why a Peach-house, or a house of mixed fruits trained fan-fashion, should be the stale monotonous thing that it is sometimes represented. There is the back wall a sheet of blossom or fruit, the front trellis is the same. Underneath on the floor there may be all sorts of plants that delight in a cool airy house and partial shade. In our own house here, for instance, there were in spring eight thousand Geraniums in pots a perfect sheet of various shades of blossom, from white to crimson; and elevated above these, on pots turned upside down, there were specimen plants to take off the even surface. All summer, and particularly autumn up till the end of November, it was the favourite resort of the family and their visitors. There was a bed of Geraniums 8 feet wide along the whole length, with a specimen *Statice profusa* in every other light, and on each side of the *Statice* was a specimen of *Centaurea ragusina*. The edging next the path was of *Centaurea*, *Lobelia speciosa*, and *Colerus Verschaffelti* mixed, and the effect was really splendid.

Now, for an amateur or any one fond of display of this sort, a house managed thus is surely calculated to give a greater amount of pleasure, and I fancy both the flowers and fruit could be produced with about the same labour

required for a house full of fruit in pots. At present there are fifteen thousand Geraniums in the house, which are more or less in flower, and a more delightful promenade is scarcely conceivable in a house from which a full crop of excellent fruit can be obtained. With regard to the difficulties which lie in the way of a beginner, as to learning the different points belonging to the two systems, I would have no fear in finding gardeners who would teach a novice how to manage planted-out and fan-trained trees as soon as any one could reveal to him all the outs and ins of the pot-system. The labour and skill required in the former case is certainly not more than that which is indispensable in the latter.

It may be asserted that fruit trees, when planted in borders under glass, make rampant and unfruitful wood, and no doubt under improper management such will be the case. But this is an evil which can be prevented and remedied in cases where it may occur; and however much can be said in favour of pot-culture, it is not right to single out cases of mismanagement as disparagements to the planting-out system. By all means let both methods have fair play and no favour, and their faults should be as faithfully written on their faces as their merits. To use an old Scotch proverb, "Our sins and debts on this score are often mair than we think." The old method of roots in borders and heads on trellises may yield less pleasure and labour, but it has the merit which nine out of every ten will first consider—namely, that of yielding more and finer fruit. D. THOMSON.

VISITS TO GARDENS PUBLIC AND PRIVATE.

MR. WARD'S, THE ROSERY, IPSWICH.

"A PROPHET hath no honour in his own country," thought I, as on a very muggy morning this last November, after four and twenty hours soaking rain, I set out to inquire my way to find the world-known raiser of John Hopper. "You bees looking for parson Ward," says one, "he as lives next the hospital." "No, I be'ant!" in as broad Suffolk as I could muster; "it's Mister Ward, a nurseryman." "Doan't know." After many fruitless attempts I lighted on one somewhat more knowing than his predecessors. "Ah! it's he as lives at California." Well, I hadn't seven-leagued boots or Nadar's Giant, and so I couldn't venture on the diggings. Then it was explained to me that this was a suburb of Ipswich, and that in that direction I should find my man. Well, despite of dirt and mud, of which Ipswich seems to have a very fair proportion, I set off for California, which I found was on a tolerably good eminence; and after sundry inquiries and bafflings I came at last in front of a very modest unpretending-looking house, with a green-house close to it, which a board announced to me was Mr. Ward's Rosery. It was, I am bound to say, as unlikely a place to find anything of rosarian interest as any that I know of, and yet a most notable instance of how little we are to judge by appearances; for here in this wild blustering bill, with its poor stony soil, there is going on a series of operations which will, I hope, if its owner is spared, yet produce something worth looking at, as they have already produced one of the very best (next to *Devoniensis* the best) of English-raised Roses.

To grow Roses is one thing; to raise Roses is another—not to raise them at haphazard, as our worthy French neighbours do, but to raise them on scientific principles, to carefully select such sorts as are likely to hybridise well, and to produce desirable results. Now this, Mr. Ward has already done; and it is no slight encouragement to raisers of really good Roses to know what he has done with John Hopper. In the twelve months from October 1st, 1862, when he first sent it out, to October, 1863, he has sold 6000 plants and upwards. He kindly showed me his book, in which every order was entered, and, more than this, order upon order which he had not been able to execute owing to his stock being completely run out. When we recollect that this involves a receipt of some four or five hundred pounds, it shows what may be done by a judicious hybridiser, for this is no chance work. Mr. Ward knows thoroughly well what he is about, for Roses have not been his first love. He lived formerly with Mr. Chater, of Saffron Walden; and it was when Mr. Ward was his foreman, and, I believe, the

manipulator in the matter, that Mr. Chater by the raising of Comet first took that foremost rank amongst Hollyhock-raisers which he has ever since maintained. After some years spent with Mr. Chater Mr. Ward migrated to Mr. Bireham, at Hedenham, in Suffolk, then an extensive Rose-grower, and there he conceived the idea of carrying out the same principles of hybridisation that he had so successfully adopted in the case of the Hollyhock. Many shook their heads, and called him, as they will ever do, an enthusiast—a term which must be borne by every man who is really in earnest either for the things of time or eternity. Even his old master thought him visionary. However, he felt that he was right, and John Hopper has been the result of his enthusiasm. But he is not contented with the past, his motto is "Onward;" and I firmly believe that he will yet add further laurels to those he has already won.

It is curious with what different eyes we look at the same thing. A small tree of Gloire de Dijon was nailed to the front of his house. Most people would have passed it by, and thought it hardly worth notice; but to Mr. Ward and the Rose-lover there was much on it to look at and speculate about—viz., two well-swelled hips hybridised with one of our best dark Hybrid Perpetuals. Imagine what a sensation a deep-coloured crimson Tea Rose would make, or a yellow Hybrid Perpetual. And why not? It is this determination to strike out of the old beaten paths and to take up original notions that is a proof of genius, when common sense is also allowed to have its weight. Then Mr. Ward has some very promising seedlings. Of course, in November it was too late to see them in bloom: several of them he spoke most highly of, while others, which he pronounced equal to the ruck of French Roses sent over every year, he had discarded. He will not send out a Rose until he has found by careful watching that it is likely to do him credit.

Mr. Ward's ground, as I have said, is poor—just one of those grounds where the great value of the Manetti stock is seen; but until the present year he has also had a very large stock of fine Roses on their own roots. The dry and hot summer of this year has, however, somewhat baulked him, his plants being much smaller than usual. I wish I could convey an accurate notion of his method of propagating these. I fear I shall make but a mess of it—however, I can only do my best. In one of his greenhouses he puts about five hundred plants, from which his cuttings are to be made. His first crop of cuttings from these consists of about 1500. I should say the plants are put in 16-pots, four in a pot. His next batch is about 4500, and his next somewhat larger, so that from these he has obtained in the course of three or four months from ten to twelve thousand cuttings. His propagating place is quite a model. In a greenhouse he has glass cases over a tank of hot water, in fact a double case, but differing in this respect from other similar structures, that the fronts slide down, and consequently the drip occasioned by lifting up and down the sashes is not experienced. By this tank a heat of 100° to 120° is maintained, and great care is exercised that damp does not settle about the young leaves, and this he effects by frequent and gentle syringings. In a few days a callus is formed, and when rooted the young plants are potted-off and put into single pots, gradually inured to a colder atmosphere, and then planted out, when they make fine plants by the autumn—plants 18 inches to 2 feet in height. The beds used for this purpose are sunk somewhat below the level of the surface, as the soil in Mr. Ward's garden is so very light that to keep them watered is in dry seasons a matter of some difficulty. By this process, he assured me, his losses were not 2 per cent.

During the progress of his experiments in hybridising some curious facts have come under Mr. Ward's notice. Thus he hybridised Noisette Lamarque with Prince Léon, H.P. Of the produce of the cross one came perfectly single, of the colour of Lamarque, most vigorous in habit, but, of course, useless. Then, again, he had planted against a wall R. bracteata, Fortune's Yellow, and other varieties of Roses, but he has never succeeded in his crossing with them. His hope was to obtain an evergreen Rose about the size and colour of the Hybrid Perpetuals. Again, he has found that it is never of any use hybridising semidouble flowers, for these will not produce thoroughly double flowers. There can be but little doubt that a vast number of the

Hybrid Perpetuals which have come to us from France are seedlings of Général Jacqueminot, by far the freest seeder that we have. Due de Cazes, Vuleain, Princesse Mathilde, Paire de Terre Noire, &c.—Roses which cannot have a permanent place in our lists, however they may please for a year or two, betray their military origin. Mr. Ward avoids this by only using double varieties, and by saving only impregnated hips. These latter he has found, he fancies, to be much finer and larger than those which are naturally impregnated.

Amongst the results of his labours I may mention that he has a fine seedling which he intends to let out next year, and which I hope to see and report upon in due time. He has called it Mrs. Berners, and I trust it may be a worthy successor of John Hopper. He feels that he has a character to sustain, and he will not lightly forfeit it. Then he has another under trial, which he pronounces to be the most perfectly double Rose he ever saw, and a bud which he showed me seemed to confirm this opinion; but as to its merits we must wait some time before we decide.

Such, then, are a few imperfect notes concerning the whereabouts of John Hopper and its raiser; and now a word as to the Rose itself. It has, I believe, this season disappointed a good many. This I can well understand: it is one of those peculiarly tinted Roses that require a cool summer to develop their beauties, and the past summer has been not a cool but a very hot one. To this cause, and this alone, is to be attributed any disappointment that may have been felt concerning it, and I feel convinced that it will yet fully maintain the high character given to it; and if its raiser will only give us a few more in different styles as good as this, or, still better, give us a crimson Tea or yellow Hybrid Perpetual Rose, he will be gratefully remembered as one of the greatest benefactors of the Rose-growing race, and their name is Legion.—D., Deal.

LEAN-TO GROUND CURATES' VINERIES.

In the "Curates' Vineries," which from time to time have been noticed in your columns, what is the object in having the glass framework ridge-shaped, thus— Δ ? Would there be any objection to putting another row or two of bricks and having the framework flat? With the framework flat there would be a considerable saving in cost. Of course, one end, say the north, must be a little higher than the other in order to throw off the rain; but there would be no difficulty in this, especially in situations where the ground lay on the incline.—B.

[The ridge-shaped roof is to throw off the water, and also to offer two favourable angles to the sun. Another or even two more rows of bricks may be added if height is required; but they must be placed so as to leave pigeon-holes for ventilation. A lean-to ground vinery with a one-inch board for the back would do very well, but it should be placed on bricks so as to be properly ventilated, and the sloping glass roof should be facing the south or south-west—in fact, such a structure would be very cheap, more easily made, and quite as efficient as the ridge-shaped roof. The back wall or board of such a vinery should be 18 or 20 inches high, its front from 6 to 8 inches. Grapes would ripen well in such structures, and for ground on the incline they would be more convenient than ridge ground vineries.]

GRAFTING VINES.

As an answer to "T. R. O.," and other inquirers, we reply that if old Vines are in a good border and strong it would not be advisable to root them out, inasmuch as you will get the sorts you want to introduce into a full bearing state sooner on established stocks than if planted in the usual way. If your established Vines are not in good condition then root them out by all means, and introduce your new varieties by making a good border and planting young healthy Vines in the usual way. The Barbarossa is, in some cases, a rather shy fruiter; and it is more than likely that its being put on to a less vigorous-growing sort, like the Black Frontignan, might have a beneficial effect on it in this respect. If you mean the Canon Hall Muscat and Muscat

of Alexandria for early forcing, you will not find them well adapted for that purpose unless with the best means of bottom heat, and even then they are not to be depended upon for early work. They may both be termed shy setters, and they take a long time to ripen. The White Frontignan, on which you propose to graft them, would answer this purpose better than either of the two; but if you do not mean to begin forcing before the end of January or early in February, the Muscats succeed very well, but will not be ready for table nearly so soon as Chasselas Musqué, Royal Muscadine, and Buckland Sweetwater, all of which will ripen a month before the Muscats, and are good early white Grapes.

If the state of your old Vines is in all respects satisfactory, the inarching of green wood to green is by far the quickest and best way, and is performed by taking a deep slice off the sides of both the stock and the Vine you desire to introduce, and tying the two together with a piece of soft mat. The union takes place sooner and better thus than when a scion of last year's growth is grafted on in the usual way. —D. T.

EXHIBITING ROSES.

"D." BEGINS by asking, What is a truss? as if there were no question upon the subject of exhibiting single blooms or trusses. I think he should have first asked, Must Roses be shown in trusses? He says he thinks they should—1st, because a Rose naturally of a medium size can never be exhibited large (I suppose he means large through disbudding), unless by the loss of refinement; and, 2ndly, that a truss is the natural production of the shoot, and that therefore disbudding ought not to be allowed. These seem to be his only objections to disbudding.

As to his first reason, I entirely differ from him in thinking it a sufficient one. The practice would probably only obtain with medium and under-sized Roses, and I believe, if properly carried out, would tend only to increase the size of such Roses and bring them more on a level in that respect with those naturally of a larger size, and thus add uniformity to a pan of flowers.

That increase in size is, as a rule, obtained at the cost of refinement I emphatically deny. I speak from experience, having 800 to 1000 plants. Of course, I am assuming that moderately high cultivation is employed, and that the roots are moderately thinned. I know quite well that excessively high cultivation and immoderate thinning will produce "coarse" Roses (if any Rose can be coarse); but the abuse of a thing is no argument against its moderate use.

Then as to his second objection, I confess I do not see any logic in it. What is the natural production of a shoot in a Carnation, a Pink, or a Hollyhock? What the natural state of a bunch of Grapes, of many a Peach and other fruit tree? Why should the natural production of the shoot of the Rose be more regarded than the natural shoots of other flowers and of fruits? "D." seems to forget that Roses shown as cut flowers are florists' flowers, should come as nearly as possible up to the florists' standard, and be judged by such standard. Effectiveness produced by trusses should not be aimed at, but perfection in each individual bloom.

If that can be more nearly reached by means of disbudding, why should not the rosarian disbud as well as the grower of the Carnation, the Pink, or the Hollyhock?

I take it that form, substance, colour, and size are the points to be regarded in a cut Rose, and in the order named. The first two, and perhaps the third, depend much on the variety, irrespective of cultivation; but the last in the smaller kinds of Roses can only be attained by high cultivation and liberal disbudding.

"II. How many trusses (blooms?) should be shown?" I am happy to say I entirely agree with "D." in his remarks under this head and on No. III.

"IV. Ought the classes to be separated?" I was, I think, one of the first—if not the first—to advocate separation. I do not know that I have any more to say upon the question, except to observe that, in my opinion, if any variety of Rose should be shown in a separate class, that variety is the Moss. There is scarcely one of this variety—I do not know one—which would pass muster as a florists' flower. Moss

Roses are truly beautiful as Moss Roses, and should be shown with their lovely buds on the trusses—in fact, should be shown in trusses—but they are altogether out of place in a pan of Roses shown for form, substance, and colour—i.e., shown as florists' flowers.

V. As to Fancy classes. I think that the money expended on these would be better laid out if given for the best English-raised seedling. The prize might accumulate until a Rose worthy of it was produced. Giving prizes to huge bunches of Roses is, in my opinion, a great mistake.—P.

FRUIT ON STEPHANOTIS FLORIBUNDA.

I HAVE NOW, on one of the plants here, a fruit measuring 5½ inches in length and 8 inches in circumference. The plant is growing in a No. 3-sized pot, and has fruited two years in succession. From 70° to 80° of moist heat is given from April to the time of flowering, when the plant is removed to the conservatory, where it remains until September. It is then taken back to the stove, and is kept in a temperature of from 50° to 55° during winter, with a rise from sunshine in spring; little water is given from October to February, only just sufficient to keep the leaves from flagging.

No attention is paid to impregnating the blooms, although I find several formed in August continuing in a small state until April. These I thin to one, and the fruit rapidly swells and is ripe about December.

A mixture of equal parts of peat, loam, and leaf mould, with occasional waterings of clear liquid manure, suits this Stephanotis well.—W. LANFEAR, Gardener to T. Parry, Esq., *Stleford*.

CUTTING OFF LEAVES FROM STRAWBERRIES.

It was not my intention to enter upon this subject again; but your correspondent, Quintin Read, appears to think I am annoyed at an expression used by him in an article contributed to your Journal of October 20th, in which the word "barbarous" was applied to the indiscriminate removal of the leaves from the Strawberry plants previously to the winter setting in. But I assure him that I by no means feel annoyed at anything that he has contributed to your Journal.

Your correspondent also states that I adopt a rough-and-ready way of manipulation by the introduction of a novel instrument for that purpose in lieu of a knife, in the shape of a scythe; yet he states that many gardeners, as soon as the fruit was gathered, used to cut or mow off all the leaves. And when the term "mow" is used, I take it for granted that a scythe was used to perform the operation. If so, in what shape or way can the scythe be pronounced a novel instrument for that purpose? I by no means consider it a newly-introduced kitchen-garden implement, for I have seen it used for many purposes there besides mowing-off Strawberry leaves. For instance: I have seen it used for mowing off Asparagus stems when ripe, and also Potato haulms; I will not go so far as to say weeds, because I never did see these mown down; but I have frequently heard of this being done; and I do not think the scythe would be at all out of character if used to mow off all the spent or decayed stems from the perennial plants in autumn, providing we had a large bulk, and stood free of everything else in order that we might get a good swing. A practical man, and such as the one that has mown off the Strawberry leaves and Asparagus stems for the last ten years in this place, I am quite sure would mow them off quite as well as he could cut them off with an ordinary pocket-knife, and with one-fourth the time and trouble. I have seen the scythe used in more than one large place to mow the Box edgings to the gravel walks in a kitchen garden. Although this may appear strange to your correspondent, nevertheless it is done, and in such a way that it does credit both to the man and his director.

In reference to produce of fruit from the quarter of an acre of Keens' Seedling, I was perfectly satisfied when I stated that we picked two bushels at one time, and little short of half-a-bushel daily for three weeks.

I may add that I mowed the leaves off the Keens' Seed-

lings this season in the second week in July, after I had selected all the strongest runners for forcing in pots: therefore they had the same time to make and ripen their growth as those in pots, this being a considerable time before the setting-in of winter, as your correspondent will perceive. The plants are now 2 feet in diameter, with fine luxuriant foliage, and every particle of them well matured. Nothing is left to present an unsightly appearance or for the wind to blow away into any other part of the garden through the winter months.

Your contributor remarks that his plants are 2½ feet in diameter. I presume that includes the old spent or decayed foliage. Unquestionably his plants will make some growth; but I cannot see in what way they are ripened when almost entirely concealed by their old spent leaves; and if we should have any such cutting winds during severe weather, I fear it will deprive his plants of their clothing that he allows to remain through these mild autumn months. That appears to me like heating a house full of tender plants during mild weather, and allowing the fire to go out when severe weather sets in.—J. B. C. P.

RIPENING GRAPES IN A GREENHOUSE WHERE FLOWERING PLANTS ARE GROWN.

My Grapes do not ripen well, and many bunches have been both soft and sour, though having as much fire as the gardener wished for. I am told that the reason is, that I have Geraniums in the house; and I have been told, also, that "Grapes never do well in a greenhouse." I shall be much obliged by your telling me whether this is the case, and whether Grapes cannot be successfully cultivated in a greenhouse where they are not required to be ripe before August or September, and from whence the flowers (with a few chance exceptions), are removed in May to a cool conservatory to bloom there? The Grapes are chiefly the Black Hamburgh.—AGNES.

[Yours is just one of those cases where we would like to have more minute information regarding the particular conditions under which your Grapes have failed to ripen properly. There is no reason arising from the atmosphere of your greenhouse why they should not ripen if the plants are removed in May and the house then managed as for Grapes; but if the gardener has not full liberty to study the Grapes independently of any particular consideration for the plants, then you must not blame your gardener if your Grapes are not good. Grapes may be thoroughly ripened and be excellent in a greenhouse in the one case, but there are many chances against their being so in the other. If your Grapes have ripened under similar circumstances in former years, then the cause of failure this year must be looked for in something else.]

Generally speaking, Vines that are left to take their chance in a greenhouse till early summer require a good deal of fire heat during the latter part of the season to insure their ripening properly, particularly in cold localities. We cannot give any more definite answer to your questions as to the correctness of your gardener's statement in the absence of other details.]

ROSES IN THE SUBURBS.

As the season for transplanting has now commenced, perhaps a continuation of my last paper on the above subject may be considered not without interest and utility by those readers of THE JOURNAL OF HORTICULTURE who are dwellers in the vicinity of large towns, particularly as space compelled me to close my former communication with the Roses of 1862. Before proceeding further, however, I would impress upon all who are about to procure fresh stock the absolute necessity of careful planting if they wish to attain success. When plants on the briar are received from the nurseries it will usually be found that they have been planted much deeper than they ought to be, especially when placed in their final positions. There are many reasons for this system of deep planting at the nursery which it is needless to enlarge upon here; but they do not apply to private grounds, in which it ought never to be practised,

No briar stock ought ever to be deeper in the ground than the collar; and if plants have already been planted so, upon removal the error should be rectified, and a few handfuls of soil placed round that portion of the stock which has previously been buried too deeply, in order to protect it for a time from exposure to the atmosphere, to which it has not been accustomed: this soil may be removed gradually at a favourable season. It is also a good plan to place a handful or two of light earth round the bud of plants worked upon the Manetti before finally covering-in. It encourages root-action from the bud itself as well as from the foster-stock; so that eventually a double set of roots exists, and the stock, if preferred, may be entirely cut away, leaving a Rose upon its own bottom.

But to return to the discussion of suburban Roses. Tea Gloire de Dijon, hardy in constitution, free in growth, in bloom the first and last, is the best of all Roses for unfavourable localities, and indeed for anywhere else. Even an inferior flower of this variety is striking and better in quality than the best of some kinds, while a perfect bloom is unsurpassed. I can scarcely believe this should be considered a Tea Rose except in scent, but rather a hybrid from some of the strong-growing Bourbons, possibly from Souvenir de Malmaison, which it much resembles, though stronger in growth and different in hue.

Jacqueminot it is scarcely necessary to comment upon, except to remark that it is the parent of almost all the high-coloured varieties introduced during the last few years. If a cross could be obtained between this and Gloire de Dijon (and I do not see why it should not succeed), we should acquire a new strain of Roses of most valuable properties and of novel hues of colour, much superior to the loose high-coloured Hybrid Perpetuals, almost all alike, and the flimsy Teas that are now season after season foisted upon the Rose-growing public.

Jules Margottin, Mesdames Knorr, de Cambacères, Domage, Rivers, Ladlay; Anna Alexieff, Comtesse de Chabrilant, Lord Raglan, and Triomphe des Beaux Arts, are so well known that to describe them in detail would be useless repetition. The following, however, are less common. Hybrid Perpetuals: Mdlle. Therese Appert, a sort of pale peach or blush, very free and late bloomer; full, flatish flower; of moderate growth. Madame Bruny (this I am disposed to set down as really a Bourbon), peach; full flower; strong grower. Pæonia, bright crimson; large, full flower; free and late bloomer, good habit. Prince Imperial, rose colour; one of the largest and fullest flowers grown; not popular at the nurseries, as it is one of those kinds that send up one or two leading shoots only, and consequently take two or three seasons to make a saleable head—nevertheless, it is a good flower in the rosery. Large Roses that open well generally make the best for unfavourable situations. Maréchal Pelissier, light rose, globular, succeeds where Auguste Mié will not, and is somewhat in that line of colour. Narcisse (query, Tea or Noisette?—is entered as both in the lists), though small is always in bloom; the flower is beautifully formed, and the colour exquisitely pure, light yellow, canary centre; the growth is slender, yet it does well near town. Bourbon Apolline, light pink, pretty; rampant, straggling grower. The above-named I have found or seen to do very well, and are worth the attention of suburban rosarians. There are a few old favourites, such as Général Brea, Madame Guinoisseau, Mathurin Regnier, and Gloire de Vitry, still under trial.

To such enterprising spirits as are inclined to venture out of the beaten track, and experimentalise a little on their own account, I would point out the following varieties of 1863 as likely to repay investment. I have seen them myself, and have received accounts of them from sources which I have every ground for believing to be entirely trustworthy.

HYBRID PERPETUALS.

Alfred de Rougemont.—Crimson purple; fine shaped and full flower; vigorous habit.

Baron Adolphe de Rothschild.—Fiery red; large, full, and vigorous. I am assured that this is likely to be a first-rate variety. The raiser is to be depended on.

Baron de Rothschild.—A fine Rose, more lilac than the above, and scarcely so large and vigorous.

Jean Goujon (Margottin).—Brilliant red; a large saucer-

profiled, flat-faced, full flower, with regular petals; vigorous and decidedly good.

Le Rhône.—Vermilion it is described as, but certainly not the vermilion of artists, which I have never seen in any Rose; free bloomer, tolerably free grower, and a good garden sort.

Mrs. Wm. Paul.—Purplish-red or crimson; full generally and well shaped; habit free. I saw this in bloom in the forcing-house in spring, and in the grounds three weeks ago, so it may be considered a true *Perpetual*, which too many so-called are not; *Madame Boll*, for instance.

Henry IV.—Another Rose somewhat the colour of the last, but scarcely so large and double. It is, however, a late bloomer.

Vainqueur de Goliath.—Brilliant red or crimson, shaded deeper. I am told that this is a first-rate Rose. Messrs. Wood describe it as the best flower of the season. The habit is vigorous and good.

Madame Alfred de Rougemont.—White, tinted, incorrectly described as the "shape of the Cabbage Rose." It appears to me to be really a Hybrid *Noisette*. It is worth a trial for its colour; good whites are scarce.

BOURBON.

Louise Margottin.—Lighter than *Louise Odier*, and every way excellent.

Those cultivators who have not yet given their orders had better not defer any longer. The finest plants are being lifted every day in large numbers, and the run upon certain favourite kinds will speedily exhaust nurserymen's stocks. There is one encouragement, too, for the doubting to become growers at once—viz., a considerable reduction has taken place in the price of plants this season.—W. D. PERON, *Homerton*.

RESTING ORCHIDS AND PITCHER-PLANTS.

I SHALL be much obliged for some information about the resting of Orchids that flower in autumn and winter. The rule given is, that as soon as the bulb is fully made, or the growth of the season completed, water must be gradually withheld until the growing season returns. Is this rule applicable to winter bloomers? For example: *Dendrobium*: noble formed its bulbs by the first week in August, and has been kept dry till now, when it begins to push the bloom-buds. Must it still be kept absolutely dry? *D. densiflorum* has rested nearly as long, till the fluting of the bulbs shows the effect of the long drought. It will bloom in February. Must it still starve till then? *Oncidium flexuosum*, at rest for these three months, has been forming its bloom-panicle nearly as long. *Ionopsis paniculata* (on a block) has been in flower for some six weeks, and I think would long ago have withered, if I had not frequently wetted it. This makes me doubt the propriety of a dry treatment for other species, either blooming or about to bloom. *Phajus Tankervillei*, and *P. Wallichii*, again, should these be now quite dry?

Would Mr. Appleby, to whose courtesy I am already much indebted for a solution of some queries, be so good as to give us a little article on the season, duration, and degree of rest-drought in winter-blooming Orchids, and the relation of the rest to the formation and maturation of flowers?

I wish, also, to be told, how those plants should be wintered which in summer delight in having their roots bathed in water? For example: *Nepenthes Rafflesiana*, which with other species, Mr. Dominy keeps standing, the pot nearly submerged, in a tank of water in the growing season; and *Philesia buxifolia*, which I was directed to keep in a saucer of water. I did not ask how long in either case, but I conjecture that both the stove and the greenhouse bog plant require rest, and ought not now to be standing in water. Please to tell me if I am right in my conjecture, and if so, what condition their roots should be in for the next two months as to moisture.—*ORCHIDOPHILUS*.

[Your remarks upon the different varieties conclusively show that you not only love the peculiar and lovely flowers which this great natural order produces, but are bent upon making yourself acquainted with the best modes in practice for bringing about a satisfactory floral display. That you may have the full benefit of our practical experience, we shall

reply to your remarks in a way which we trust will be generally applicable to the many other amateur growers who are beginning to found collections.

As a general rule, all growers must bear in mind that this tribe of plants, like all others, must have a season of growth and a season of rest. Unlike, however, almost all the other families of plants under cultivation, this one may be subjected to very severe drought without the systems of many of the plants being materially injured. A corresponding degree of excess in moisture, if aggravated by cold, would be fatal in most cases. What all Orchid-growers have to study, is the maintenance of the proper balance of moisture and drought at the different seasons of growth and rest. It is very easy growing a collection of this kind of plants, many people say. So it is; but it is one thing keeping plants in life, and another thing cultivating them to a high state of excellence. Now, I maintain that next to keeping the houses at a temperature suitable for the well-being of the class of plants growing therein, are the comparative degrees of drought and moisture, both for root and "branch," for encouraging successful growth, and floral development.

There has always been, and always will be, some little difficulty in explaining the precise treatment necessary for any given species or variety of plant, because in the first place no two men grow them in exactly the same ingredients. Some adopt ordinary drainage in the make up of their compost, and ply the watering-pan more cautiously; others, again, give ample drainage, so that water may be poured upon the plants almost at any time; and both may be very successful cultivators. One remark may, however, be made in passing, that whenever the compost becomes a sodden mass where air cannot freely circulate, the plant will lose every day afterwards, however cautiously treated. There can be no two opinions about this. A free circulation of air amongst the roots is at all times highly necessary to attain success.

All *Dendrobiums*, from noble upwards, require a season of rest varying from four to two months. But for all this it is not to be supposed that they must during that time be kept dry at the root. Certainly not. A season of rest, as I would have it understood, is a gradual diminution of temperature, and a proportionate restraint in the supply of water. *D. noble* will live in a greenhouse temperature, even supposing it should occasionally fall to 36° in severe weather, with impunity. Little or no water during such a period may be given, and flower-clusters will show themselves on the well-ripened wood at every eye. *Densiflorum*, on the contrary, if subjected to such treatment for any length of time, would die; but it again will winter well in a temperature that never falls below 40°. Some of the more rare ones—such as *Farmeri* and *onosmum*, must not even be reduced so low, but all will flower much better if set in a house with a minimum temperature of 50°, and the atmosphere kept comparatively dry. Thus, "*ORCHIDOPHILUS*," and others will see that some Orchids will live and bloom to advantage in 36°, and all the race of *Dendrobies* in houses from 50° downwards. Whenever there is too much appearance of shrivelling in the pseudo-bulbs, then want of water is the cause. The party in charge must learn to have his eyes open to administer a remedy when any flaw occurs. As to *Oncidium flexuosum*, with pseudo-bulbs matured, and showing bloom-panicles, it should now be in a temperature ranging from 50° to 60° in the night, according to relative temperature out of doors, and moistened whenever it appears dry. *Ionopsis paniculata* has been correctly treated. All block plants must be watered when dry, at whatever period of their growth. If they are allowed to shrivel it will take months to make up the loss. *Phajus Tankervillei*, and *P. Wallichii*, are both terrestrial Orchids, and should be dry at no season. Now they are showing their flower-spikes, and may be either grown in a temperature of 50° or 60° to suit growers, but it is not wisdom, even in those wishing to retard them for show, to subject them to a temperature lower than 45°.

Phadenopses, *Vandas*, and *Ærides*, again, coming from such a warm region, are better never to be in a temperature lower than 60°, although in very severe weather it might fall to 55° without doing the plants any harm. Moisture here must also be regulated according as the systems of the

plants absorb it, and neither more nor less ought to be given, or withheld.

From these remarks it will be observed that I have mentioned two great fundamental points in culture—a proper and relative degree of heat, and a proper and relative degree of moisture. There is yet one other which is of the utmost importance to be observed, and that is the keeping all plants as near the glass as possible. Let these three points be intelligently observed and acted upon, and the rest will follow.

The roots of all Pitcher-plants, and other bog plants that usually stand either in saucers or tanks of water during the season of rest, should only be supplied when the saucers and other receptacles become dry, and then only moderately. We have a plant of *Rafflesia* just now with immense pitchers, and leaves about 20 inches long—not a naked-stemmed plant, but clothed to the pot-rim with leaves—which is treated as above recommended. Little weakly plants of *Sarracenias*, *Philesias*, &c., are all the better of being plunged into pots two sizes larger than the one they are growing in, and the interval filled up with moss, firmly put together, which is kept constantly moistened. This is better for this style of plant than placing them in saucers of water.—G. A.]

PROPAGATING ROSES BY CUTTINGS.

I HAVE a good collection of standard Roses. Could I rear some dwarfs from them the same as Gooseberries and Currants are reared in the open garden? I have an old Cucumber-frame—where the Cucumber vines died off about three weeks back—would a few cuttings grow in that? J. CHOYCE.

[The great majority of Roses strike freely enough in the way to which you refer. The best time to put the cuttings in is about the middle of October. Good strong firm cuttings should be selected from 9 inches to 1 foot long, with just a heel of the previous year's growth. The leaves should be removed from the bottom half of the cuttings, but all the rest left on. They should then be put in up to the first leaf left, and made firm in the soil with the foot, the same as is usually done with Currant cuttings. They will callus before winter, and root in the following season, and make nice little plants. The best place to put them is in any light, dry, common garden soil where they will escape the midday sun. It is not, however, yet too late to make a successful attempt, choosing strong well-ripened growths and preparing the cuttings as described above. The shelter of your Cucumber-frame will be a great advantage to them; and if the winter be mild they will so far callus, and if lifted and put into a little bottom heat in spring they will root. There is not, however, that certainty as regards the results of the operation when delayed till now as would have attended it earlier in the season. We wish more of our fine Roses were so propagated, and grown as dwarfs instead of being hoisted on to the top of an unsightly stem to look like a mop.]

A NEW CONSTRUCTION OF SMOKE-FLUES.

IN THE JOURNAL OF HORTICULTURE I see there has been much discussion as to the two systems of heating plant-houses—by hot water, and the old way by smoke-flues. On a large scale no doubt the hot-water mode is the better, although more expensive in the erection, and afterwards in fuel and renewing boilers, &c. For small houses heating by smoke-flues is the best. They are sometimes "rickety," and give out smoke; this is often the effect of bad materials, and their not being properly seen to. Now, I think it is possible to improve them by making the sides of the flues of long pieces of clay (call them clay planks), 20, 24, and 30 inches long, 9 inches broad, and 3 inches thick; in one end of these planks let there be a groove $1\frac{1}{2}$ inch wide and $1\frac{1}{2}$ inch deep. In the other end make a feather or tenon $1\frac{1}{2}$ inch long and 1 inch broad. This is what a joiner calls groove-and-feather. The sides when set up to be bedded in mortar, and before they are put into each other, the tenon to be coated with mortar, and after they are joined, the half-inch not occupied by the tenon to be filled up with mortar from bottom to top. The sides for the corners of the flues

to be right-angled or square, 14 to 20 inches long to suit the length of the flue, and that is the reason for giving the different lengths mentioned before.

As this flue is not so deep as those in common use, it should be wider—say 18 or 20 inches broad; the covers to be 18 or 20 inches long, 12 inches broad, and 2 inches thick, check-lapped in the common way. For sinking the flue opposite doors, common brick will require to be used, with flagstones for covers.

Upon the side of the house where the flue is far from the furnace, the flue might be blackwashed, which will give a greater radiation of heat; and large flower-pot flats, set on the flue here and there, and filled with water, will make the air of the house more humid.—W. T., *Aberdeenshire*.

GARDEN BOILERS.

It would be a great advantage to gardeners in general if the sensible article written by "W. W." page 409, had been rendered a little plainer by showing the connecting-pipe of the two boilers, and also the position of the flow and return pipes at their connection with the boiler.

If this should meet the eye of any boiler-maker who has manufactured the simple and excellent boilers described by "W. W." I am sure it would answer his purpose, as well as benefit the public, if he would advertise both the construction and price of such boilers; and with a view to promoting such a desirable object, I am sure "W. W." would receive the thanks of many if he would communicate with some known manufacturer to that effect.—T. L.

[I am sorry that I did not show the exact position of the feed, the junction, and the flow-pipes in my first sketch; but for the information of "T. L." and others I will now endeavour to furnish the requisite explanation.

There is a flange at the front end of 2 (page 410), to which is fixed the feed-pipe, and at the other end is the outlet, but on the opposite side of the boiler, and forming the junction to the upper boiler. At the front end of 3 is a flange in connection with the flow-pipe: consequently the flanges at the two front ends are on one side, and occupy respectively the coolest and the hottest position, and the other two flanges are on the other side of the boiler to them.

I am told that these boilers are what are called "steam chests" at calico-printing and bleaching works, and cost a very small sum—in fact, so little that I do not like to name it. I wish that some maker would advertise them in your pages.—W. W.]

ROSES IN POTS FOR GREENHOUSE—STRAW COVERS FOR PLANTS.

In answer to a correspondent, "L. R."

Teos.—Safrano, Devoniensis, Comte de Paris, Niphetos, Vicomte de Cazes, and Gloire de Dijon. *Noisette*.—Aimée Vibert and Solfaterre. *China*.—Mrs. Bosanquet and Fabvier. *Bourbons*.—Armosa and Souvenir de Malmaison. *Hybrid Perpetuals*.—Auguste Micé, Baronne Prevost, Géant des Batailles, Général Jacqueminot, Louis Peyronny, Caroline de Sansal, Madame Vidot, and William Jesse. If you are to order these plants, you will be wise to leave a little latitude to the Rose-grower after telling him what you want.

As to straw covers. If you can manage wood at first, such as those mentioned as in use at Keele Hall and Trentham, they would be more economical in the end. Mr. Fish uses straw because he cannot obtain wood conveniently. He makes most of these covers neatly, that they may be used for going over glass sashes, as well as over earth pits where there is no glass; but for the latter purpose some of the nicety may be dispensed with. As to the wood, pretty well anything is used, but new covers are chiefly made out of elm boards fresh from the saw, an inch thick and half an inch thick respectively. Of course, deal, larch, or Scotch fir would be better. We shall suppose that the covers are 6 feet by 4, and for this size we will require three pieces of one-inch-thick wood, 6 feet long, and from $3\frac{1}{2}$ to 4 inches wide, and eight pieces of the half-inch wood, 4 feet long and 2 inches wide. The men rip up these in a wet day. Then on stools or tressles place two of these long pieces square, at a distance

to take in 4 feet, and a third piece in the middle. These three pieces bear all the weight of the cover. Then across these at each end tack or nail down a four-foot piece across, divide the space from the ends into four equal divisions, and give a cross piece to each. Fasten all these down, and you have a skeleton of three longitudinal and six transverse pieces. Turn this skeleton frame upside down and you have what may be called the bed for the straw to be laid on. Wheat straw drawn and the heads cut off before thrashing is best. Lay the straw on regularly so that the ends shall not protrude between the cross pieces, and rather more than 1 inch thick, to permit of squeezing tight to the thickness of the side and central pieces. Then a cross piece of 4 feet in length is put across at each end, over the straw, opposite to the cross pieces beneath, and a nail is passed through holding the upper and lower cross pieces and the longitudinal pieces firmly together. Opposite the other four transverse pieces a tar string goes from side to side, and is made very tight so as to keep the straw firm and with a smooth surface. A very good way is to have fine tacks for each string. Fix the string on a side piece with a tack, let it be held by one on a cross piece halfway to the middle piece, one on the middle longitudinal piece, one again between, and the last at the farther side piece. This is one of the best ways of making all secure, but there are other simpler modes. The great object is to hold the nice clean straw as firm as in a blacksmith's vice.

There might be six cross pieces on the upper side as well as the lower side; but then the weight is increased, and the cross pieces keep the damp against the straw and rot it sooner. Well made as above, if the covers have much of a slope, the water runs off them beautifully, and it would require a strong frost to go through them. These straw covers have sometimes been tarred with a brush on the upper side, which rendered them still better conductors of water; but it was thought that the straw did not last so long, as when exposed to much sun it became more brittle. One of these covers when fresh or a year or two old is considered as good a protection as two or three mats. The cross pieces beneath keep the straw from the glass sashes when so used. For commoner purposes, such as temporary protection to cold pits where there is no glass, straw is often used, when merely fastened to old hurdles without so much nicety. If to be made of fresh wood, they are worthy of the above trouble. There can be no question that wood altogether would be more economical in the end. There is no greater mistake than to suppose that gardeners can always act up to their convictions and belief as to what is best.—R. F.]

CHRYSANTHEMUMS IN THE CRYSTAL PALACE.

As all our local shows are now over, and out-door border-flowers are looking very shabby, I took a stroll to the Crystal Palace on Friday, to see what remained there; and to my astonishment, I found the centre avenue a perfect blaze of beautiful fresh blooms in beds, round, oval, and diamond-shaped. The flowers were tastefully arranged and intermixed, displaying a great variety of showy colours. They varied from the size of a button to that of the largest Dahlia, and were beautifully incurved, especially the gem of all the Chrysanthemums the Jardin des Plantes, which stood towering above all the rest, four or five pots in a bed bearing five or six blooms.

Mr. Williams, the superintendent, informed me that he grew all the blooms on the second bud, which he commenced selecting from the end of August, that he watered with weak guano water, and that he housed them in the beginning of October. The Pompones are all well bloomed, and Mr. Williams's system of training is very good. Many of them are grown on one stem of from a foot to 18 inches high; they then branch out pyramidally, and, no sticks being used, their appearance is exceedingly pretty. Look at the plant from whichever side you please it is all well bloomed. I like Mr. Williams's mode of training very much.

My object in sending you this notice, is for the information of some of your readers that may wish to have a collection to bloom in conservatories from November to Christmas, and

with this view I took down the names of the most showy varieties, which I give as near as I can from a rapid glance.

LARGE VARIETIES.

Yellow.	Red.	Blush and Pink.

POTATOES.

(Concluded from page 428.)

THIRD PLANTING.

MARCH 29th.—Planted the Negro, Freebearer, Haigh's Kidney, Fluke, and the Lambton Castle Kidney. The last three were too limited in quantity, and grown on a piece of shaded ground from which it would not be fair to take the weight of crop as a criterion; nevertheless they were a fair crop, the Lambtons especially. They averaged 13½ tons per acre. I still dub them the Lambton Castle Kidney, having had them from the Earl of Durham's; but I feel almost certain that their real name is the Jackson's Seedling. My brother, who was paying me a visit, declared they were the best Potato for eating of all my kinds. They are a second early.

September 28th.—Lifted the above sorts, the rector, Mr. Morris, and my brother being there to see. The first root of Negro weighed exactly 13½ lbs., and gave thirty tubers. The largest weighed 1½ lb.; four from 1½ to 1 lb.; eight from half-a-pound to a quarter of a pound; sixteen from 4 to 2 ozs.; and one half an ounce. A considerable number of diminutive tubers I did not count, which I am sorry for on account of a statement from near Moreton-in-the-Marsh, which I copied out of the *Oxford Chronicle*:—

"A Prolific Potato.—An extraordinary root of Potatoes was recently dug up in the garden of the Rev. G. D. Wheeler, of Wolford, which produced over seventy to the root, one of them weighing over 2½ lbs., nine half a pound each; and there were ten large sets. The residue consisted of smaller ones, many of which might be used as seed." Now allowing one tuber to weigh 2½ lbs; nine, 4½ lbs; ten large sets, suppose them to weigh 3 ozs. each, say 2 lbs.; and 1½ lb. for the "residue," the total weight will be 10½ lbs. Now as I allow no weight to my root for residue, I think the Negro may lay claim to be the heavier by 3½ lbs. The average weight of the crop was 30½ lbs. per 4 square yards, or rather better than 16½ tons per acre. The heaviest root of the Freebearers weighed 5½ lbs., and gave four tubers only. This variety throws but few small Potatoes. The crop averaged 26 lbs. per 4 square yards.

These two varieties I cultivated on account of their tubers arriving at a large size and being consequently appropriate for baking. They are both of them of good quality for boiling, and of the best and latest-keeping sorts. I will merely observe in passing that the ground occupied by the

above three plantings has been consecutively cropped by me with Potatoes for sixteen years, part of the time only on the ridge-and-trench plan. Brussels Sprouts and Broccoli occupied the trenches; and they are now spreading nearly over the whole surface of the ground, so as to make it appear almost incredible to a stranger visiting the garden how and where the Potatoes could have grown.

FOURTH PLANTING.

Before I begin to write the description of this, I must thank an unknown brother bee-keeper who kindly sent me on the 16th of last April, a Stewarton bar-and-frame hive, filled with varieties of Potatoes from Scotland. Did they come from Renfrewshire? The idea of a bar-and-frame bee-hive being presented to one of the straw-hive and milkpan school like myself! thus trying to induce one, as it were, to become scientific! Nevertheless, the characteristics of the package were worthy of the kind-hearted Scotchman, who thus added the idea of future utility to present bounty. I beg to assure my unknown friend that I will, if I am spared, turn the hive to future account; and that I have sufficient command over myself not to dread the small end of the wedge, though, had I the time and the means at my command, there is no telling at how many scientific tangents I might fly off in that way. I am happy to inform a brother bee-keeper that my hives are populous and well provided with winter store.

To return to our subject. I cannot do better than quote their descriptions in the words of the giver.

"No. 1. *Rough Red*.—A relic of the olden time—the finest eating Potato known, and an immense cropper before the advent of the disease, to which it almost totally succumbed, being now nearly extinct in these parts—procured from an old farmer who has kept it pure for the last seventy years. Can only be grown now with any measure of success on moss or old lea ground.

"2. *Rough White*.—Another old esteemed variety.

"3. *Gryffe Castle Seedling*.—An excellent Potato of fine quality, a large cropper when well manured—a fortnight earlier than the succeeding.

"4. *Walker's Second Early*.—The very best the writer ever grew of the many sorts now classified as above, or as Scotch Regents in the South; fine quality, largest cropper, best for general crop.

"5. *Seedlings of 1862, from Flukes*.—This coarse yellow variety and the *Rough Red* the only sorts here that mature seed."

I thought I had planned how every foot of this garden was to be occupied previous to the above arrivals. I knew not what to do in an emergency like this, but the idea struck me of digging out a trench of soil a spit deep from between the rows of Asparagus, and filling it up again with fresh good compost, then sowing the Marrowfat Peas there, and, when the growth of the Asparagus haulm had sprung sufficiently, to peg it down within a foot or so of the soil in lines on each side, and then stick the Peas. Watered them well and often with liquid manure (house sewage). The pegged-down Grass afforded a natural mulching, and such a crop of Peas was the result as I seldom remember—so much ground gained for ever. When the Pea haulm was cleared away, the Asparagus did not cast any shade, and I do not much expect that we shall have cause to deplore a diminution of heads next spring—at any rate the Potatoes took the place designed for the Peas in the open quarter.

May 12th.—Planted the Scotch Potatoes. During their progress their tops made enormous growth, so much so, that I was obliged to stake and tar-cord them within bounds twice over. My man spoke dubiously about their being "all tops and no bottoms," and I used to appease him by telling him to rest his mind till we took them up, and that then we should see.

The *Rough Reds*, true to their description, in one day after the lightning and thunder experienced here about the beginning of October, became blackened with disease, and I took them all up on the first dry day about a week afterwards. They turned out to be a fine sample of Potatoes. The *Walker's Second Early* proved the bulkiest crop, 15 tons per acre. The *Gryffe Castle Seedling* threw the finest tubers, many of them "with laughter cracking both their sides"—jovial-looking fellows in rough jackets. At the time of their taking up we cooked specimens of them

all, and they looked white and well in the dish; but it was too early for them to be fine in their flavour; it would not be fair in me to give judgment on their qualities in that way before next February. I am sorry to say that the *Rough Reds* up to this present date, November 3rd, are half of them decayed with the disease. No other of the kinds have shown the least symptom of it, nor, I am happy to say, with the exception of the *Negro*, have any of the sorts which I have grown this year. There has been complaining in our streets by the slovens, who allowed their crops to remain needlessly long in the ground, about disease, but they get no sympathy from me. With the exception of the *Rough Reds*, the tubers from the north will be a great acquisition in this neighbourhood, for, being strong-toppers and of a disposition to crop, they will, particularly to the allotment-holders whose land is chiefly of a light and stone-brashy nature, be just suitable.

Some of the seedlings I have great hopes of, though, as they arrived to me in a small letter-envelope and weighed scarcely more than an ounce. I can for the present only judge of their peculiarities thus:—Four of the little tubers flowered with light pink blossoms; one with a dark pink blossom; three with white blossoms; and six gave no blossoms at all. Nine produced round Potatoes, two *Kidneys*, and three are *Fluke-shaped*. All are white but one kind, which has a pink crown and eyes, and which is also covered with the robin's-eye protuberances similar to the early *Walnut-leaf*. In form this is like its *Fluke* parent. I have them in careful keeping. Another promising seedling I also retain for next year's proving.

Having an hour's time or so to kill ere the *Woodstock* train arrived at the Reading station, I went to Sutton and Sons', and spent the time very pleasantly in viewing their collection of seeds, and in overhauling their Potatoes. I found them well up in the varieties both old and new. I wanted particularly to see the *Early King* in the mass, and I must say it runs out too much for my liking, being a mass of all shapes; it will require a careful selection of its handsomest seed annually to rectify this undesirable feature. Hamper after hamper was goodnaturedly hauled out and opened for my inspection, till I fairly apologised for the trouble I was giving, and then a rough-skinned white Potato came to view, a very magnet for me. It was labelled "*Newest Regent Seedling*," a first-rate-looking Potato, round, and not nearly so deep in the eye as the generality of the *Regents*, and the roughest-jacketed fellow I ever saw. Half-a-gallon of them are now reposing amongst my stores. Two sufficiently large for cooking were measured in; they boiled firmly mealy, having if anything a rather yellower tinge than their namesakes. Although too early for a true judgment to be formed they have the *Regent* smack, and I thought it to be of a finer farewell flavour. They will prove a late store variety, and for the cockneys, whose palates chiefly prefer the *Regents*, these will come in admirably.

Some of the finest *Regents* I ever saw, were grown this autumn at *Rushbrooke Hall Gardens*, near *Bury St. Edmunds*, by Mr. Wigg; and the crops of *Peaches* and *Nectarines* on the open walls, and the *Pears* and *Apples* both on the walls and on espaliers there, were a sight to behold. I believe Mr. Wigg had had a *Royal George* Peach tree with its crop photographed a few days before my visit. The largest of *Flukes* were being dug from the old dark sandy loam, (exactly similar to the soil in *Rushbrooke Hall Gardens*), in the garden within the walls of *Carrisbrooke Castle*, *Isle of Wight*, some six weeks ago; but the careful scrutiny and the contemptuous jerking aside which many of them underwent told a tale of disease, as I watched the operation from the ruins.—UPWARDS AND ONWARDS.

VULGARITY IN CUCUMBERS.—We never dreamt until recently of the existence of an aristocracy of appetite. We overheard in a market the following brief dialogue between an old woman and a little girl, while they were standing in front of a vegetable stand:—"Grandmother," said the little girl, "buy some of those Cucumbers." "No, my child," replied the lady. "Why not?" asked the little girl. "Because I should hate to be seen carrying them home, when everybody knows they are only a penny a-piece!" The little girl did not appear to appreciate the excuse.

CEPHALOTAXUS FORTUNEI AND CEPHALOTAXUS DRUPACEA.

Fig. 1. Female plant of *Cephalotaxus Fortunei* with its fleshy drupes.

Fig. 2. Section of fruit.
Fig. 4. Male catkin magnified.

Fig. 3. Male plant with its inflorescence in the axils of the leaves.

Among the very many beautiful plants, for the introduction of which into this country we are indebted to the skill, enterprise, and good taste of Mr. Fortune, there are none which have more interested me, as an ardent admirer and extensive cultivator of hardy evergreen trees and shrubs, than the two species of *Cephalotaxus*, of which I now have

the pleasure of sending you fruit-bearing specimens. One of these is very appropriately named after its talented introducer, "*Cephalotaxus Fortunei*," and the other "*Cephalotaxus drupacea*."

Some confusion existed on the first appearance of these remarkable plants, the former having been rather hastily

pronounced to be the male, and the latter the female form of the same species; but as you will see by the specimens now sent, the impression originally entertained was erroneous. That they are distinct species, having their male and female inflorescence on separate plants, and are, in fact, dioecious, has been allowed.

You will perceive that I have sent you two specimens of each species—the female with its fully developed fleshy drupes, and the male with its incipient inflorescence in clusters at the axils of the leaves, which develops itself in the spring and scatters its pollen around.

Both *C. Fortunei* and *C. drupacea* are thoroughly hardy

and highly ornamental. They will grow in almost any soil, being amply furnished with large fleshy roots, which lay hold of the ground and extract abundant nutriment.

One very valuable quality which these fine plants possess is their thriving under the dense shade of other trees, thereby forming an undergrowth of glossy luxuriant foliage, and giving a rich dressy effect to places which otherwise would look bare and meagre. The landscape gardener indeed possesses in these oriental Yews materials which, judiciously handled, cannot fail to produce a change of no ordinary character in our ornamental grounds.

Mr. Fortune found them both in the northern districts of

Fig. 1. *Cephalotaxus drupacea*. Female plant with its drupes. | Fig. 2. Male plant with its inflorescence.

China, *C. Fortunei* attaining the height of 60 feet, and *C. drupacea*, which is of much more compact and dwarfer habit, that of 30 feet. I believe I am correct in saying that they are both indigenous to China and Japan.

The specimen plant in our nursery of *C. Fortunei*, from which I cut the branch, is now covered with purplish plum-shaped fruit or drupes, of which there cannot be less than three thousand at the present time, and is altogether a most attractive object, as its gracefully pendant slender branches are actually weighed down with the enormous clusters of

purplish berries, contrasting well with the long, linear, lance-shaped leaves, which are of a peculiarly rich lively green.—ROBERT PINCE, *Exeter Nurseries, Exeter*.

[Excellent as our figures are, they necessarily convey a very inadequate idea of the fine effect produced by the great profusion of beautiful drupes with which the branches are literally studded, and we can quite conceive what the appearance of a tree described by Mr. Pince must be.—EDS. J. OF H.]

CENTAUREA ARGENTEA AND CENTAUREA CANDIDISSIMA.

AT page 372 of THE JOURNAL OF HORTICULTURE, MR. J. ROBSON seems to suppose that there are more sorts of the Silvery-leaved Centaureas in cultivation as bedding-out plants than the two mentioned above. No doubt there are some beautiful sorts not yet brought out as bedding plants. I can look back through forty years and recollect several

such, but the above two sorts are all that I know at present to be used as bedding-out plants, or as conservatory ornaments.

What Mr. Robson quotes as *gymnocarpa* is only *argentea*, and the *ragusina* is only *candidissima*.

As to the rival merits of the two plants both are exquisite

gems, but any one who may have cultivated both plants to a large size as conservatory ornaments, cannot, I think, hesitate in preferring *argentea* to *candidissima*; and I am not sure, or very decided, which of them will ultimately become the greater favourite as a bedder. The two plants must both be seen of a large size before their merits can be properly appreciated.

I cultivate both sorts extensively, and they are both so beautiful, yet so different in their habits, that it is difficult to say which one likes best when planted out. The only rival they have is *Cineraria maritima*, which has merits quite equal to either of them.

We had a ribbon-bed here this season which was highly admired. It had a central row of the two *Centaureas* and the *Cineraria*, with a row all round of Purple Orache, and outside that a row all round of *Stachys lanata* (another hardy white-leaved gem), then next the grass a row round of true *Lobelia speciosa* from cuttings, the only way that can be relied upon for obtaining it true. A better edging would have been the *Arabis albidia variegata*, about which another correspondent in the same page makes similar mistakes as does Mr. J. Robson about the *Centaureas*. My experience of the *Arabis* is, that the one called *albidia variegata* is whitish-sulphur in the spring and yellowish-sulphur in autumn, just as *Bellis aeneabotolia* becomes green in summer and beautifully variegated in autumn and winter. We cultivate two sorts of the variegated *Arabis* here, the above and the *lucida variegata*. This is more yellow than *albidia variegata*, and is easily known from *albidia*, which is covered with pubescent hairs, whilst *lucida* has a smooth, bright, shining foliage.

I trust the above will set bedding-plant-cultivators right about these valuable and most useful plants.—JOHN SCOTT, Merriott Nurseries.

WORK FOR THE WEEK.

KITCHEN GARDEN.

TRENCH, dig, and ridge-over every spare inch of ground whenever the weather will permit these operations to be advantageously performed. This is particularly to be observed in gardens the soil of which is of a clayey nature. *Cauliflower*, give air freely to these, and also to Lettuce plants under glass. Indeed, the sashes should merely be used to exclude frost, and to throw off rains, for the plants will do all the better in spring if kept hardy and stocky over the winter. *Celery*, take advantage of the first dry day to earth-up closely any that may have outgrown the previous earthing-up, and be prepared to protect the ridges in case of severe frost. Dry stable litter answers very well for the purpose; but where they can be procured, straw or reed shutters are preferable, as being more easily applied, and causing less litter, and they are also useful in excluding wet. *Peas*, those sown on a warm border, and also the Broad Beans sown at the same time, as advised, will now be peeping up, and should have the surface soil stirred about them, and a covering of decomposed leaf mould laid over the rows, and also, in the event of cutting winds prevailing, some branches of spruce fir or birch stuck in on the windward side will be useful. Gravel walks should come in for a share of attention in sweeping and rolling. Coal ashes are an excellent material for the back walks, as they bear the winter traffic well, and are always pleasant to walk upon. If frosts set in let the manure necessary for the whole of the spring cropping be wheeled out, laying it in heaps either on the spot where it is to be used, or as near as possible to it. What is not required for immediate digging should be piled in small mounds, and soiled over to prevent evaporation. Take the

opportunity of bad weather to forward the making of labels for the various crops, tying mats, cleaning nails, preparing shreds, and looking over stores.

FLOWER GARDEN.

Flower-borders should now receive a good top-dressing with some well-prepared compost. This should be forked in, and the surface of the borders left as rough as possible, which will give them a fresh appearance, and be of great service in pulverising stiff soils by the action of the frosts of winter. Thus the soil will be reduced to a more mellow state for spring operations. The weather is still favourable for executing alterations, and where these are in hand they should be prosecuted with the greatest possible dispatch. Planting or the removal of large trees or shrubs cannot be finished too soon, for it is of the utmost importance that the plants should be afforded some chance of making fresh roots before the cutting winds of March arrive. See to even small plants being secured against the wind, for these are often greatly injured by being blown about after planting, which a small stake and a few minutes' work would prevent. Standard Roses, which by the weakness of their shoots and the paucity of their blooms this season, are showing evident symptoms of decay, should have all the surface soil taken off down to the roots, and all the suckers removed, after which, a thick coat of well-rotted dung should be laid round them, and covered with a portion of the soil. Tea-scented, China, and other tender Roses that will not stand the severity of our winters, should now be protected by strewing a good thickness of fern, or any other dry material amongst the stems of the plants; this, with the addition of some spruce fir boughs stuck all over the beds will afford them all the protection they require. Those varieties which are budded on the standards may be easily protected by tying on a few furze branches round the head, securing the whole with a strong stake to protect it from the boisterous winds of winter.

FRUIT GARDEN.

Prune, stake, and tie Raspberries, and mulch with some light manure, which may be lightly forked-in in the spring, as it is imprudent to dig deeply about them. If any transplanting or root-pruning of fruit trees has yet to be done, let it be attended to without further delay, and see that those exposed to the wind are securely staked before leaving them. Also, let the ground be prepared for fresh plantations, and the trees planted as soon as possible. Fruit trees are injured by the accumulation of moss and lichen on their branches. Where the hand cannot reach it, a dashing of lime will effect its destruction.

GREENHOUSE AND CONSERVATORY.

We have already alluded to the ill-effects of humidity and stagnant air in plant-houses, as evils at this season to be guarded against most particularly; but these are of minor importance compared with one of our own creation, evidence of the existence of which we not unfrequently see in the drawn and unhealthy occupants of greenhouses. We allude to heat, which, judiciously applied, is of course of the first consequence, but, employed without judgment, becomes a fertile cause of the evils above described. It must be borne in mind, that a spring or summer temperature without the sunlight of one or the other, is altogether an anomalous state of things, and one which cannot be consistently pursued with objects so susceptible of such influences as plants. Above all, high night temperatures should be avoided. We are convinced by experience of the value of the practice of employing night-coverings, and of thus dispensing in a great measure with the use of fires. The leaves of Camellias, Oranges, &c., are liable to a dark scum. This should be cleared away by a sponge at this period, especially as a portion of the interest in pot plants depends on cleanliness both with regard to the leaves and the pots. While the principal collection of *Chrysanthemums* is in bloom, a selection should be made of the best and most useful for distinctness, and succession of sorts.

STOVE.

Do not encourage any fresh growth among the plants at this season; rather aim at that kind of routine management which will serve to consolidate the growths already made, and to develop the blossoms of the late-flowering plants in a proper way.

FORCING-PIT.

This is a good period at which to introduce a good quantity of shrubs and bulbs for forcing purposes. Azaleas, Daphnes, Persian Lilacs, Moss and Provence Roses, Sweetbriars, Honeysuckles, Rhododendrons, Kalmias, Ledums, Rhodoras, the more advanced Hyacinths, Narcissus, and Tulips, may now be fairly started. A sweet bottom heat of 80° maximum, and a top heat of 65°, will be necessary, whatever the structure.

PITS AND FRAMES.

Look well to those containing stores for next summer, and have efficient protecting material always in readiness, with which to cover them whenever the weather is unfavourable.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

TREMENDOUS gales and rain, with skiffs of snow, have much lessened out-door work. We have taken up some more Sea-kale and Rhubarb for the Mushroom house. Earthed a piece of a Mushroom-bed, and spawned another piece: raked leaves when the wind and wet would permit; trenched or began to trench ground; attended to all the vegetables coming on as mentioned in previous weeks, giving plenty of air to Cauliflowers, Asparagus, Lettuces, Endive growing, &c.; and when too stormy for the men to work usefully or comfortably out of doors, set them to break up wood, make straw covers, point sticks, and wash pots, as we never like to see pots standing out of doors in winter. Even in sheds they are best washed clean, so as to be ready for use. We once had a system of fines, but gave up when no one could be fined but ourselves; but we daresay we shall have to start again. Amongst fines none could be more legitimate than those making people remember who put a plant into a dirty pot, left pots standing about everywhere, laid pots down in a heap of all sizes, or when moving small pots took too many at one time as a rope between the hands, to the danger of cracking or breaking several in the centre of the rope. As to pointing small sticks, it is amusing to see men detected making as many scrapes and cuts to form a point as if they were polishing an ivory bodkin. We recollect the late Mr. Joseph Knight insisted on such pointing being done with two strokes of the knife.

FRUIT GARDEN.

Much the same as in previous weeks. It has been too wet for planting out of doors. Tied Peach trees in house, and planted some Vines inside at back of a vinery to help to give those in front a little rest.

ORNAMENTAL DEPARTMENT.

Attended to plants in house, removing those which were fading, and supplying with fresh. Placed leaf mould and loam under cover for use. Cleared all the rubbish from the pleasure grounds. Removed Dahlias that had stood in a dry house for a fortnight with their stems down and tubers up, and plunged them in dry earth in a close shed behind the conservatory. So treated we have scarcely ever lost a tuber. We do not like placing them in earth at once, but like all moisture to be drained from the roots and stems. We generally leave the latter about 6 inches long, unless much frosted, and if damp has lodged and remains there the centre is apt to rot, and thus the buds may perish. If once thoroughly dried a little moisture afterwards would not hurt them. The bed of earth is generally covered with a rough stage crammed with Fuchsias, &c., for the winter. We once met with a fatal instance of overdrying Dahlia roots. An amateur had obtained a fresh supply of novelties, a sharp frost came on in an early autumn night. He and his man Friday went out late, cut over all the Dahlias, took up the roots with the large tally attached, and placed them close to a back flue in the greenhouse. When examined in spring the tubers had nothing but skins, and scarcely one grew. If the roots had been earthed-up a little in the ground, or merely treated as above, we do not believe that any such misfortune would have happened.

Took up the greater portion of Gladiolus, and put them in by the heels in a dry place to mature the tubers. Some of the tops are yet too green for that purpose.

The weather will have proved pretty well whether we

were right as to keeping bedding plants in old hotbeds instead of dry pits and frames. In the old hotbed we have suffered a little from damp, but from reasons several times given our plants are small, as we cannot take cuttings early without injuring the outline of the beds. A spare room with plenty of light is better for keeping such plants than a frame over an old hotbed, and the place being dry, a little sprinkling of dry hay would keep out a great amount of frost. Some of our friends who have small orchard-houses without artificial heat, would find it much easier to protect their bedding plants there in winter than in damp old hotbeds, as the air might always be dry and pure, and in severe weather it would be easy to cover them, and far less covering would do, and in continued frost and dull weather it might remain on for a good while. The great secret in keeping such plants when in darkness is to insure as much dryness and coolness as will be safe, and yet arrest growth. These conditions secured, we have had Calceolarias and Scarlet Geraniums that never saw light for six weeks, looking as well as if they had been covered up only for a night. The inside temperature was little above 33°. If the temperature had been from 40° to 45°, we may judge what the result would have been. Many try to keep old Geraniums in their cellars, and fail because the cellars are too damp and too hot. They would succeed better with them in a garret, where there was some light, and where a little protection could be given to them in cold weather. Everything growing must have light. We have some Scarlet Geraniums which in beds averaged 2 feet in height, and 2½ to 3½ feet in diameter of head, so pruned back that from a dozen to twenty of them, with their roots, after being dipped in lime, were squeezed like a faggot into a nine-inch pot, and if we could keep these docked plants in spring, they would be larger next summer than they were last summer. Now, to keep these in the easiest way, the stems must not break before spring, but owing to the continued mild weather these faggots of plants are beginning to push little green leaves, hardly discernible as yet, but seen from their greenness, and after that the plants to be healthy will require more light than they would otherwise have needed. They would do exceedingly well on the floor of a spare room moderately lighted, whilst all the young plants from cuttings stood near the window. Growing plants must have light, it is of less importance for those at rest. The faggots of Geraniums before they break may be treated very much as we would treat a Dahlia root, or a Gladiolus.—R. F.

COVENT GARDEN MARKET.—DEC. 5.

The supply at this morning's market was unusually good, especially as regards vegetables, and the demand being also good, former prices were fully maintained. Fruit of all kinds is also plentiful, particularly Pines, which are more than sufficient to meet all requirements, and Apples and Pears. Foreign Hamburgh Grapes are now over; but importations of White Grapes have come in from Portugal. Cobs have risen in price, the finest samples now bringing 160s. per 100 lbs. The only addition to the varieties of Pears previously reported is Beurré Rance, of which and of Newtown Pippin Apples, there are some very good samples.

TO CORRESPONDENTS.

EVERGREENS FOR COVERING A WALL (Orta).—We know no plant that covers a wall so beautifully as the old *Cotoneaster microphylla*. As a sub-evergreen *Jasminum nudiflorum* is a lovely plant, and at this dull season it is a sheet of yellow blossoms.

ROSES TO BLOOM IN WINTER (T. G.).—Unless you can cover your Roses with glass we fear you will not now get them to expand properly, unless the season prove unusually mild. You could protect them from slight frost by mats, figli domo, or stout canvas. Your newly-received Roses will take no harm for two months if carefully heeled-in and secured against high winds.

OBTAINING HYDRANGEAS WITH BLUE FLOWERS (J. H. L.).—The following from the pen of the late Mr. Beaton was published in our columns some years since:—There is one disadvantage in August-made cuttings well known to gardeners, which is, that the flowers of them come all of one colour, and that the same as that of the parent plant, whether it be blue or pink; but those made in February may be made to flower blue or pink at will. If the mother plant produced blue flowers in the former seasons, and you force it in February, cut off your cuttings as soon as they make three joints, and when they are rooted place them in a rich light compost, save one half leaf mould or very rotten dung, and the rest of any good garden soil, they never fail to produce pink flowers; whereas, if taken from a pink-flowering parent, and after rooting growing them in strong yellow loam, with about a sixth part of iron filings mixed with it instead of sand, nine out of ten of them will produce blue flowers. We never could get an August-cutting to differ in colour from that of the parent plant. The reason seems to be that the juices of the parent plant have already, by a season's growth, formed the substance—or the organised matter, as physiologists call it—out of which flowers are produced, so that no after-treatment is able to counteract the effect; whereas cuttings separated from a plant at so early an age as when they only attain a few inches in length, and are then made to grow in iron rust and loam otherwise impregnated with iron, which is well known to favour the production of blue flowers in the *Hydrangea*, the organised matter referred to is formed from juices impregnated with iron oxide, and so produces blue flowers. The intensity of the blue is, we believe, according to the perfect oxidation of the iron. Chalk-water never fails to counteract this effect of the oxide on the flowers, as we have often proved here, so that, to give the fairest chance to the experiment of getting blue *Hydrangeas*, we would recommend the cuttings to be taken as early in the spring as possible, to strike or root them in red sand, to grow them in nothing but red loam and iron filings, according to the above proportions, and never to water them but with rain water; but we are not sure whether rusty water from hot-water pipes would not add to the success of the experiment—at any rate, this rusty water is not injurious to these *Hydrangeas*. In some parts of the country the natural soil will produce blue *Hydrangeas*, and in such places it is difficult to meet with pink ones; and what is singular enough, the *Rhododendrons* will flourish in such soil, although apparently devoid of all traces of vegetable matter. There is also a kind of peat earth which invariably turns the pink to a blue *Hydrangea*, but all the peat that we have access to here does just the contrary. To have pink *Hydrangeas* next summer, let us, therefore, make our cuttings now from pink parents; and, if we wish them blue, we must take the cuttings at this season from blue-flowering plants, for we cannot alter the colour now."

DESIRABLE ACQUIREMENTS (A Young Gardener).—Both free-hand drawing and mechanical drawing are useful to the gardener, but especially the latter, because it facilitates the plotting of beds in geometrical figures, ground plans, &c. Botany is not essential, but no gardener can practise enlightenedly unless he understands the physiology of plants and the rudiments of chemistry. Read "The Science and Practice of Gardening," published at our office.

VINEY AND PINERY (An Old Subscriber).—As far as we understand, you mean your fire to heat the chamber, and in the pit above it to grow the Pines. If so, the cast-iron plates will do admirably as a covering to the chamber. The sides of the pit might also be made of these plates if deemed desirable. The pit, we presume, is for the Pines, and will no doubt do well, as we presume the fires will give you enough of bottom heat. You state, however, that you intend the house chiefly for Vines, and to begin forcing them at the latter end of February. If so, to give justice to the Vines you should not have them nearer than 5 feet from stem to stem and spurred. To make the best of both Pines and Vines you should have a double front to your house in winter, between which the Vines could be placed and kept cool in their dormant state, and could even be started there before being had up to the roof. We advise you not to attempt too much. You have no chance to succeed well with Peaches against the back wall of such a lean-to house. The Pines would require too much heat for the Peach trees in winter. You might have such trees in pots and tubs, start and set the fruit in a cooler temperature, and bring them to such a back wall to swell and ripen; but even then to give flavour to the Peaches would require more air than would suit the Pines. By doing away with Pines you might have Peaches on the back wall, starting them gently so as to have the fruit set before the Vines were much moved, and the pit you could appropriate to Fig- and other fruit trees in pots, so low as not to shade the back wall. Keep in mind that if you cover the glass roof thickly with Vines, neither plants in the pit nor trees against the back wall will continue long fruitful and healthy. When Vines are 2 or 3 feet apart, gardeners get a good deal out of their houses as under-crops, but they have little in them when the roof is shaded all over. If 5 feet apart there will be a good amount of light that will reach the floor and the back wall.

ROUGH PLATE-GLASS FOR GREENHOUSE (Mrs. U.).—Provided you glaze throughout, at the sides as well as the top, Hartley's rough plate-glass does not require shading for ordinary greenhouse plants. We do not think your mode of glazing would answer as the parts glazed with 21 oz. glass would need shading if the sun shone powerfully upon them. Of course, if the sun did not reach the parts glazed with 21 oz. glass, that would do equally well with rough plate. We have no experience of the stove you name, yet we feel certain it would not suit you. A small saddle boiler, with two four-inch pipes running all round your greenhouse, would answer your purpose better than any slow-combustion stove, and you can obtain the boiler and pipes very cheaply by sending a rough plan of your house to a hot-water apparatus manufacturer. He would send you an estimate for what you required, and give you an efficient apparatus for the sum necessary to obtain a stove large enough for your purpose, and which would be worn out by the time that the boiler would be none the worse.

GESNERA ZEBRINA NOT FLOWERING (A Subscriber, Grimsby).—Your treatment is right, and we can only account for its not flowering by your keeping it in a close moist atmosphere, which is more conducive to growth than flowering. Place in a drier atmosphere, and give abundance of air and light as soon as the flowers begin to burst the calyx, but still keeping the plant in a temperature averaging from 55° to 70°. We give ours the ordinary heat of a vinery, and by the time the Grapes are ripe the plant is in full flower. A specimen, 2 feet high and 4 feet across, is one of the finest plants for filling vases in drawing-rooms, they continuing in bloom a long time and coming in when flowers are scarce. We fear you have been supplying guano water in too strong doses; do not apply it next year, and give a plentiful supply of water, but let the plants be dry before watering. Too much water is against the flowering of this plant, as it hinders the ripening of the flower-stems.

GRAFTING MUSCADINE VINE (Idem).—You may graft the Vine on the old wood, taking off the rough outer bark and washing it so as to prevent any composition used for washing the stems penetrating into the wood. We have grafted them on the wood of the year when about half ripe, and on wood one, two, or several years old, and find success is certain in all cases when the operation is properly performed. Tongue or whip grafting is the preferable method. It should be done in the beginning of March, leaving a few eyes on the old Vine to draw the sap past or into the graft. We prefer inarching to grafting, which we have practised on the young and old wood indiscriminately. If you have the plant of Lady Downes' we would advise you to inarch it on the old Vine at the place required, deferring the operation until the Vine has commenced growth. It would take in about six weeks, when it might be detached from the parent and trained up alongside of the Muscadine, which would produce fruit, and be cut down when the graft was sufficiently grown to supply its place.

CUCUMBER FOR EXHIBITION (Idem).—Kirklee's Defiance, Long Gun, and Star of the West are all handsome, long, and good.

WALL BANKSIAN ROSES NOT FLOWERING (Sigma).—Prune them back about one-third of their length and train the branches about 9 inches from branch to branch, so as to admit sun, light, and air. They ought to flower next year.

ROSES IN CASES (Idem).—Plant-cases are not too dark for Roses. You might try Fabryer, Lucullus, Archduke Charles, and Infidélité de Lisette, China Roses; and Devonians, Saffron, and Madame Bravy, which are Tea-scented. Mrs. Bosanquet (China) does well in a pot. They can be had from any of the Rose-growers who advertise in our Journal. We fear, however, if you have no place but a plant-case, that they would give you nothing but disappointment. They will flower well enough in your case, but they want light, fresh air, and thorough exposure to mature the growths made after flowering. If you have a cold frame you might grow them in it, only removing them into your plant-case to flower.

INSTRUCTION IN GARDENING (Mrs. S. E.).—The young man must be placed as an assistant under some head gardener. You had better ask some head gardener in your neighbourhood to take the young man. A small premium will have to be paid.

PRONUNCIATION (X. X.).—We fear that a phonetic dictionary would require another dictionary to explain it.

PROTECTING ROSES (A Subscriber).—Tiffany is a kind of cotton cloth not closely woven. It may be had at most drapers' shops, or you may obtain it from the firms who advertise in our columns. Gutta percha hoods, with a little moss put over the eye and the hood upon that, are a novel invention. We have never tried such a contrivance, and cannot say whether it would answer or not. We fear it would cause the eye to start into growth if kept on in mild weather; but it certainly would be a good protection in severe and inclement periods. If you try it we should like to hear of the result. For protecting Roses we have found nothing better than a little long dry hay wrapped loosely round the buds and stems. The hay does not look very neat, but it can be no eyesore to those who consider its use. The tenderest kinds of the Tea and China Roses may be taken up and stored away in moist earth under a fence, and the shoots protected by placing a covering of straw or any kind of dry litter over them in severe weather. If a frame can be spared to put over them, so much the better. They can be planted in the beds in March, and pruned at the same time. They will flower rather later, but in other respects be little worse for moving, and in some cases it does good.

PRUNING VINES (Q. F.).—The system of close pruning recommended in our Journal, and alluded to by you, was for Vines in good condition. We would advise you to prune to the first round plump eye on the fruit-bearing shoot or spur. We make it a rule to provide for a crop; and when Vines show fruit but tardily, cutting to one eye—or even two, unless they are round and plump—is a practice that provides for appearance at the expense of produce. Our advice is, Prune to a full round eye, wherever it is situated; if it is the third or fourth no matter, but the nearer they are to the stem the better, as there is then no superfluous old wood appropriating to its own use that nourishment which would, were they pruned closely, be expended on the young wood and in perfecting the fruit. We fancy your border is wet, and the light to which the young growths are subjected not sufficient to cause the first leaves to be healthfully formed nor fully matured. Try longer pruning, and communicate with us again if no better results attend your efforts.

RICHARDIA WATERING AND POTTING (Idem).—Give it enough water to keep it fresh—that is, keep it drier by half during winter than when growing vigorously. Put it in March, and keep it standing in a pan of water during the summer. It is an aquatic, and requires the soil to be kept moist at all seasons; but it flowers more freely by being kept rather dry in winter.

REMOVING A LARGE CEDAR OF LEBANON (S. G.).—Your best way will be to cut round the roots at the distance of about 4 feet from the stem, making a trench and cutting every root at that distance, or even nearer if there be few at that place. Then fill in the trench again and let the tree stand till next September, when it may be removed with a better prospect of doing well than if it were transplanted now. A good ball is useful; but a careful preservation of all the roots at the time of removal is equally so.

ROSES IN WINTER (R. J. B.).—The Roses you named will stand our ordinary winters without protection. A little dry hay may be wrapped round the buds in severe weather, and it is tied on with matting the winds would not blow it off, and the garden would be kept tidy. Some people wrap the buds or heads in tiffany, which affords a slight protection, but nothing beats a hay handage.

DESIGNS FOR FLOWER-BEDS (T. Andrews).—We never undertake to supply designs or to plant them. In "Flower Gardening for the Many," which you can have from our office free by post for five postage stamps, you will find several designs from which you can select.

ROSES FOR PILLARS (H. N. G.).—Général Jacqueminot, brilliant red; Duchess of Sutherland, pale rose; Gloire de Dijon, yellow, shaded with salmon; Souvenir de Malmaison, flesh, edges bluish; Eugène Appert, scarlet, shaded with crimson; Jules Margottin, bright cherry.

MICE IN GARDEN WALL (Moses Walker).—Procure a pot of phosphorus paste from a druggist and spread it rather thickly on thin slices of bread. Place this, in small pieces, in their haunts. Or arsenic made into a paste with a little lard, and spread on thin slices of bread and put in their holes, will soon kill them. These are poisons, and must be kept out of the way of domestic fowls and animals. We would advise you to wash the trees with Gishurst Compound at the rate of 8 ozs. to the gallon of water, which will make the buds distasteful to the vermin, using the poison besides.

SILVER SAND VERSUS YELLOW (Wyeside).—Both master and man are in part wrong and in part right. River or drift sand is quite equal to silver sand for the striking of ordinary cuttings—as Fuchsias, Geraniums, &c.—or strong coarse-growing plants, those which are softwooded especially. Silver sand, on the other hand, is indispensable for propagating Heaths or such plants as have fibres smaller than a hair. We have struck cuttings in rivulet drift sand; but when we can obtain silver sand cheaply, and have river sand to buy, we prefer the former, as we think it is the purest of all sand, being, as it is, fine grains of white quartz, which is very insoluble, whilst yellow sand is more easily soluble, and is generally combined with soil. We should not despise pure river sand at our door for the mere fancy derived from purchasing what we could do without. Why not try the yellow against the silver sand, and thus solve the problem by the best of all tests—experiment?

STARTING VINES IN JANUARY (B.).—In the first place you should cover the border of the early vineery with some kind of fermenting material—as dung, leaves, &c., to the depth of 18 inches, on the 1st of January, and thus commence the new year in earnest. Previous to this take off the 6 inches of rotten dung and keep it away from them for the future. The temperature for the first fortnight should be 40° by night, and 45° by day, with a rise with sun of 10°. After that the temperature should be 45° by night and 50° by day, with a rise of 10° to 15° with sun. Continue this temperature until the buds begin to swell, then increase it 5° both by day and night, and by the time the buds break have the temperature 55° by night and 60° by day, and allow it to rise 10° with sun heat. Up to this the Vines should be sprinkled twice daily with tepid water of the same temperature as the house, and every available surface kept moist. Air should be given at all favourable opportunities; but after the leaves appear be careful to avoid cold draughts, which are extremely pernicious. Keep an eye on the border outside, and when you find the heat declining add more fermenting materials. If you could obtain some wood shutters and have them fixed so as to cover the border to keep in the heat and shut out the wet, they would be of great assistance in keeping up the heat of your border. By the time the Vines are in flower the temperature should be 60° at night and 10° higher by day in cloudy, and 15° or 20° in bright weather, with abundance of air or ventilation. Discontinue the syringing when the Vines are in flower, but keep up a rather moist atmosphere by sprinkling the walls, &c., twice daily, morning and evening. Give a thorough syringing after the bloom is set, and after this keep the air moist by sprinkling the walls and paths twice daily, and continue this until the Grapes change for ripening. At this time keep the air rather drier, and give all the air practicable, as far as the temperature will allow. You will stop the shoots at the eye above the fruit, stop all laterals at the first joint, and that above the fruit the same. The laterals below the bunches of Grapes will hardly push again; but if they do stop them at the first leaf, and serve the shoot above the bunch the same. After this rub off all laterals that appear below the bunch, and stop that above the bunch to the last formed leaf, and so on. When the Grapes are the size of peas thin them, and in doing this take out the smallest and those next the footstalk, and leave them so that the berries can attain their full size without squeezing themselves into irregular and deformed berries. The temperature should be 65° by night and 75° by day after the Grapes change colour, and 60° at night and 75° by day prior to that whilst they are swelling. When the Grapes are ripe remove the litter from the border, and in doing so be careful not to injure the roots of the Vines, for some of them may have left the cold soil and run into it. If so, take away as much litter as can possibly be done without injuring the roots more than can be helped; and to save them from the burning rays of the sun cover the border with a couple of inches or so of rich and rather fine mould. Too much air cannot be admitted after the Grapes are ripe, and to insure the ripening of the wood remove the laterals on the shoots, and should any difficulty be experienced in inducing the Vines to ripen the wood made, put the wooden shutters over the border. This will promote rest to a great extent; but if you have not these wooden shutters, keep the air dry in the house, but not so dry as to cause the Grapes to shrivel. A young beginner will do well to purchase "Sanders on the Vine," and keep a sharp look-out for the valuable hints contained in the "Doings of the Last Week." Your late vineery will require similar treatment, but it will not be necessary to cover the border, nor give anything like the same amount of artificial heat. If you want the Grapes ripe in August, start them in March; if in September, in April—that is, let them start naturally. We are always more than ready to reply to queries, but we do not undertake to teach that which can readily be learned by a perusal of our columns. We do not wish to discourage our correspondent, but to impress upon him the immense importance of gathering the crumbs that are strewn around before he asks us for loaves.

NECTARINE-BUDS INSERTED LAST YEAR (M. D.).—Providing your trees are healthy, we see no reason why Nectarine-buds should not produce fruit when inserted in Peach trees. We have seen Royal George Peach trees produce Nectarines or smooth-skinned Peaches on the same trees along with Peaches. Buds might be inserted in the way you have done, and many naked branches be thus furnished with fruit-bearing branches. What age were the stems you put the buds into?

UNDERCOVER FOR A FOREST-TREE PLANTATION (Iago).—If you want it for game, Furze is as good as anything, only it likes dry ground. Perhaps Privet would suit your stiff ground, or Berberis aquifolium might do. Hollies grow also pretty well under other trees. If you prefer Furze, sow the seed as soon as you can obtain it, which is often done by employing children or others to gather it from a common or waste where it grows.

GREENHOUSE, CONSTRUCTING ONE REMOVABLE BY TENANT (Henry Stapleton).—For a moveable house you will need no front wall. All you need do is to place a layer or two of stones or bricks for a foundation, and on this a plate of wood should be fixed. Into that, uprights 3 inches square and 4 feet long and the same apart, should be let by mortice and tenon holes, and they should be fastened with screws. Two feet from the bottom plate place a sill $1\frac{1}{2}$ by $2\frac{1}{2}$ inches, rebated for glass, between each upright at the ends as well as the front, only considering the doorway. You will further need a plate for the rafters to rest on at the top of the uprights. This should project sufficiently to allow of a spout being placed in front to carry off the water, or it would injure the Vines you propose planting. You will close-board the front and ends with three-quarter-inch boards (grooved), and if you have the board next the upright front glass made to work on hinges you will find it answer admirably for front ventilation. You will also need ventilation at the top of the house. The remaining portion of the front may be sashes to correspond with the rafters on the roof, and be glazed with 21-oz. glass, which is the description we recommend for the roof. The ends will, of course, be glass; 16-oz. glass is cheaper, and quite equal to 21-oz., but is sooner broken. The laps of the glass should be putted, for frost cracks and breaks a number of squares. The flue may be constructed with bricks. Two on edge would be deep enough; and if it were 8 inches wide, and stones used for bottoms and cover, and duly mortared, it would be a good flue. The furnace should be 2 feet long by 10 inches wide, and 1 foot in depth. The top of the furnace should be level with the bottom of the flue where they join (at the furnace); the flue may then run level, or but slightly rising to the chimney. The intention of carrying the flue all round your house is good, but you must take it along the front first, and along the back the last. Six-inch pot pipes would do quite as well as a flue. Whichever you employ the furnace will need building of fire-bricks, and they should be used about 1 yard along the flue, or the heat will break the stone or other covering, or pot pipes if they are used so near the furnace. We think you are misinformed that by building your house on slabs of stone without making much foundation, your landlord would have no claim. The right way is to have a plate of wood fixed to the foundation, and then the superstructure fastened to that plate by screws.

TRANSPLANTING RHODODENDRONS (A. M. A.).—The present is a very good time to transplant Rhododendrons, provided the weather be mild and the ground not too wet. A dry peaty soil is unquestionably the best; but they do very well in some kinds of sandy soil, and even soils apparently of an opposite character. The fact is, where the chemical ingredients they delight in exist, there they will thrive. Perhaps the worst place for them is a black bog too soddened with water; chalky soils are also objectionable. See an article on the Rhododendron in No. 114.

TRANSPLANTING WATER LILIES (Iago).—Any time in autumn or spring will do to remove them, taking care not to expose them to the drying atmosphere at the time of transplanting. It is best to take good large pieces 5 or 6 feet long or so, and if 6 or 8 inches in diameter it is not too much. The roots are soft and cut easily. You may safely cut your Poplar trees any time before February, but the chances are that you will not obtain such fine-formed upright stems again.

EVERGREEN SHRUBS FOR A GREEN (H. C. Cave).—As you want evergreens only, and but one plant of a kind for a space 25 yards long by $3\frac{1}{2}$ wide, the list will go a long way towards including all the ordinary kinds in cultivation; but, supposing the border to be divided into three rows, the tallest being at the back and consequently thinnest, the next size in the middle, and the dwarfest in front but thicker, an arrangement something like the following will meet your case:—Beginning with the back row, which we will suppose to require twenty plants, you may have six Hollies differing widely from each other, common and Portugal Laurel, Chinese and American Arbor Vitæ, Sweet Bay, Laurustinus, Arbutus, Ligustrum lucidum and L. japonicum, Alaternus, Spiræa Douglasii, Evergreen Oak, and common Privet. In the second row you may have two or three kinds of Magnolias, two kinds of Phylliræ, half a dozen Rhododendrons all differing from each other, one Andromeda, two Junipers, two Escallonias, double Furze, Daphne pontica, three or four kinds of Box, and the same of Berberis; Aucuba japonica, Euonymus japonica, and some others. In the front row we would have Eugenia Ugni, Kalmia latifolia, and another kind; also an Andromeda, Griselinia littoralis, Garrya elliptica, Desfontainia spicata, Eurythia liliifolia, Cotonæaster microphylla, and C. Simmonsi. Two or three Heaths and one or two Coihues, and there are such plants as Yuccas, Azalea might perhaps stand, besides which there are evergreen shrubs. The dwarfest species of Berberis is also entitled to a place in the front, and several other little shrubs might be added if wanted. We are sorry you did not include a few flowering deciduous shrubs amongst them, as their appearance when in bloom would have enlivened the mass. You may plant on a ridge if you choose, taking care that the plants do not lack water the first year; but, after being once established, they will do for themselves.

PROPAGATING CENTAUREA CANDIDISSIMA (R. J. B.).—Give your stock plant a shift at once into a six-inch pot, and keep in a cool dry or airy place, and give no more water at the root than is really necessary to prevent its drooping. Early in March place the plant in your neighbour's stove, and when the side shoots are about 4 inches in length, take cuttings and insert in silver sand in pots as for Verbenas, and place in a gentle heat. Keep the stock plant in heat, and you may then take cuttings from it until the end of April.

STRAWBERRIES FOR FORCING (Anna).—The very best plan is to plunge the pots in leaves, litter, or earth under glass, and keep dryish and cool. For modes according to your circumstances, see page 308 in "Doings of Last Week." Most likely if you plunge the pots in a bed of earth, leaves, or ashes, and strew a little litter between and over the pots, the plants will be safe enough.

KEEPING GRAPE ON THE VINES (W. H. B.).—If you do not heat your greenhouse so much as to deprive the Vines of rest, a little heating in dull foggy weather is indispensable, not only to preserve your Grapes but the plants also from damp. Abundant ventilation and gentle firing in the day-plants only, except when severe frosts occur, and then firing must be emulous at night, is what we do with plants and Grapes in the same house. The Vines will not be injured in their bearing for another year by such treatment. You will prune them immediately the Grapes are cut, and keep them cool during the next two months, never employing artificial heat to raise the temperature above 40°, nor allowing it to sink below 35°, in order to provide for the safety of the plants. It is not too late to put large Scarlet Geraniums back in October. Their being in flower is immaterial.

BIGAU PLANT CASE (*An Old Subscriber*).—The maker is Mr. R. Stocks, 14, Archer Street, Kensington Park, London, W. A letter will obtain full particulars in reply.

NAMES OF FRUIT (*R. C.*).—Your Apple, of which you sent three specimens, is the Kingston Black. (*J. Wells*).—1, Vao Mons Leon le Clerc (?); 2, Knight's Monarch; 3, Passe Colmar; 4, Beurré d'Arenberg; 5, Beurré Bose, does not appear to do well with you; 6, Red Doyenné; 7, Vicar of Winkfield; 8, Not known. *Apples*.—1, Fearn's Pippin; 2, Hunthouse.

NAMES OF PLANTS (*Conifers*).—1, *Abies orientalis*; 2 and 3, varied forms of *Abies excelsa*; 4, *Pinus strobus*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

PRIZES AWARDED TO GAME FOWLS AT THE BIRMINGHAM SHOW.

IN our list of the prizes awarded at the Birmingham Poultry Show (p. 441), will be found the name of J. H. Williams, Esq., Spring Bank, near Welshpool, as first for Black-breasted Red Game fowls; as second in the Single Cock class for White Piles, Duckwings, and other varieties; and also second in Black-breasted Reds. Our list was copied from the official record; but we have since received information that those three awards were cancelled, and that the pens to which they were awarded were disqualified.

The disqualification, we are informed, was decided because the birds, although exhibited in the name of Mr. Williams, really belonged to J. Hindson, Esq., Barton House, Everton, Liverpool, one of the Judges of the Game classes.

No severe remarks are needed from us to intensify the feeling of reprehension generally felt upon this occurrence. Neither Mr. Hindson, who awarded prizes to his own birds, nor Mr. Williams, who allowed the birds to be falsely shown in his name, can be upon a bed of roses.

BREAKING THE RULES AT THE BIRMINGHAM SHOW.

IT is commonly believed that the rules and regulations of the Birmingham Poultry Show are so carefully and wisely compiled as to form a fit basis to guide all other societies of similar character throughout the kingdom. Exhibitors, therefore, naturally expect the Directors of the Bingley Hall Show to duly provide for the faithful and rigid observance of their own rules and regulations.

This year we find it announced that by a new rule the "privileged few," who can afford it, and choose to pay the high admission fee of 10s. on Saturday, November the 28th, will be permitted to view the awarding of the prizes to the cattle, sheep, pigs, &c. but adds expressly, "the poultry, however, will not be exhibited till Monday." So far so good; but such being the tenor of the rule, I indignantly ask, How the astounding fact arose that Captain Heaton, to whom both the Silver Buff Cochins were awarded on the Saturday, and his friend, Mr. Kelleway, the breeder of the greater portion of the Cochins fowls the Captain then exhibited, were permitted to view the Poultry Show on the Saturday, in flagrant violation of such arrangements?

Was it, as now pleaded, "a pure accident," or does it not rather appear as a turning of the golden key to the upper ten—in short, a very gaudy illustration in support of the old adage, that "kissing always goes by favour?" Until this direct anomaly of rules and practice is properly explained away, myself and many other annual subscribers to the Birmingham Poultry Show, certainly intend to erase our names from the annual subscription list; as evidently "big fish break the net," whilst the little ones are the only sufferers. If not accounted for, most certainly for the future we purpose remaining among the untrapped.—**SMALL FRY.**

BIRMINGHAM POULTRY SHOW.

IT is fit that as we grow older we should have some compensation for the loss of youth, and all the charms that are its companions—courage, confidence, elasticity, freshness, strength, and hope. Not the least of these compensations is success. When a man can look back on fourteen or fifteen years of chequered life to find them crowned with success at the end, there is a feeling of satisfaction and rest which is an indescribable solace. It is the fruition of hope, the reality of expectation, and in many instances is a

full equivalent. There have been the bud and the blossom, and the fruit is in store. Sidney Smith realised this fact when, at the end of his famous receipt for a salad, he says:—

"And then, though turtle's dear and venison tough,
And ham and turkey are not done enough;
Securely full, the epicure may say,
'Fate cannot harm me, I have dined to-day.'"

It is with societies as with individuals, success is the result of exertion, and is never so appreciated as when it has been striven for and attained with difficulty. But the feeling of rest we have described is of two kinds. There is that rest which, having attained a certain object, has nothing more to do—the purpose is accomplished. There is another which, having succeeded, has to maintain its position by constant care and exertion.

The originators and the present managers of the great Birmingham Show have had to realise all we have described. They have had their small beginning, their times of depression, their difficulties and doubts, dark clouds, so dark that their silver linings could not be seen; but they have persevered and have had success beyond anything they anticipated at the outset. It is, however, the success that requires constant exertion to maintain. Before one exhibition has closed it is necessary to begin to think of the next year. The Council are men of energy. They have added new classes. Implements, roots, and corn have all been introduced into competition. While these have been provided for there has been no diminution of the original prize list. We congratulate the public-spirited men who conduct this undertaking on the progressive success they so deservedly meet with. It is truly a great Show; and those who walk round Bingley Hall, admire the arrangements, and enjoy the sight, have little idea of the vastness of the undertaking, or of the constant labour and supervision that are necessary. The greatest novelty of the present year is a new gallery running the whole length of the building, parallel with the poultry bay. Another such must be erected on the opposite side and the effect will be very good; but space will still be wanted.

The popularity of this great Exhibition is progressive, and it would be hard to assign any limit to it. It has passed from the bare exhibition of stock, and has assumed a more attractive appearance. The taste with which the seedsmen's stalls in the gallery are decorated would do credit to an artist. Trophies appear in different shapes. Roots of almost fabulous size appear—*mirabile dictu*—as the product of one of the millions of minute seeds that fill a small bag. Beautiful steam engines, and implements of every kind, chronicle the progress of agricultural mechanism. We trust we shall be pardoned the digression. We will return to our poultry; but we could not forbear the mention of these accessories to the *coup d'aile* of Bingley Hall during exhibition time—a sight which may, without affectation, be deemed unique. The constant progress of the Society, and the increasing popularity of the Show, are a well-merited reward to the originators. Nothing could be more unselfish than their enterprise, and Birmingham owes them a deep debt of gratitude. The crowded streets, the constantly driving trains, the overflowing hotels, and the busy shops, all contribute to form their ovation.

We have already stated in our columns that there was a considerable increase in the entries, and we are now enabled to say that it was not made up of inferior pens, but of excellent specimens. It will be our task to review them.

Dorkings stood first. The prize list published last week will have given the names of the successful. We will, therefore, review all the classes of the Coloured birds of this breed, giving as one proof of their excellence that fifty-four pens were mentioned in the list of awards. All the well-known names were there. Captain Hornby took first in both the classes for cock and two hens or pullets; Ladies Holmesdale and Des Vaux, Mrs. F. Blair, Messrs. Pott, Helmeson, Drewry, and Dolby cannot be passed in silence. It was an exploit to take even a fifth prize, and those who were of necessity content with high and simple commendations may urge as a proof that they have excellent birds, that they figured among the awards at Bingley Hall in 1863. The classes for Dorking Hens and Pullets were no exceptions, and they maintained the reputation of the breed. The condition and evident strength of constitution of these birds

was matter of remark. The White Dorkings were weak in numbers as compared with previous years.

Spanish were very good, and afforded a triumph to Mr. Lane, of Bristol. That locality seems favourable to the breed; but we have nothing at present equal to the days of Davies and Rake. Mr. Teebay's and Mr. Rodbard's, nevertheless, deserve mention. The birds shown by Lady Holmesdale are very good, and will be better next year.

Our next notice will be of some of the best classes ever seen—the *Buff Cochins*; and to mention them is to record one of the greatest triumphs ever achieved—nothing less than two first, two second prizes, and two silver cups in the competition with cock and two hens, and cock and two pullets; second prize for two pullets; first for two Partridge hens; and second for three Partridge chickens, all gained by Capt. Heaton. They were not easily won from had birds, but gained in the teeth of much competition against names so well-known as Messrs. Fell, Stretch, Gilbert, and Bates. Mr. Stretch, Mr. Cartwright, and Mr. Tudman deserved their prizes in Grouse Cochins. The chickens were better than the adults. The White Cochins are losing ground. Messrs. Chase, Lamb, and Dawson showed well, but the birds are not equal to those of the olden time.

Brahma Pootras are everywhere on the increase. Mrs. F. Blair and Mrs. Rothery showed beautiful birds. Mr. Teebay did the same successfully; while Mrs. Hargreaves, and Messrs. Fowler and Adams could have but high commendations, as there were no more prizes to award.

The *Malays* though not numerous were excellent, very near perfection. Messrs. Sykes and Ballance took all the prizes.

The *Crève Coeurs* were not as good as we saw at the Crystal Palace some time back.

The *Black Hamburg* class was a novelty and a success. We believe it is almost the first time they have had classes to themselves, and they justified the introduction by sending twenty-three pens of excellent birds. It was no mean competition that, after awarding four prizes, made seven high and simple commendations necessary. Messrs. Shaw, Royd, and Lingard headed the classes. One circumstance is a disadvantage in this class, and as it is evidently a growing class, it may be as well to mention it—the difference in colour makes no difference in judging, and White faces are disqualifications. The Golden-pencilled Hamburgs were excellent, and the pencilling of some of the hens and pullets such as we have seldom seen. The contest for the prize was a very close one. The Silver do not keep pace with the Golden. It must not be inferred that they were inferior birds, but we have seen them better. The class for Pencilled Hamburg Hens brought but three entries. That for Pullets but nine. These are not enough to support the classes. Messrs. Munn and Beldon were the principal prize-takers. The Golden-spangled were very good, and the same may be said of the Silver. Mrs. Pettat, Sir St. G. Gore, and Messrs. Marlor, Hyde, Kershaw, Dixon, Cannan, and Fielding all showed excellent pens, sixty-seven in number, and bringing twenty-six into the prize-sheet; but the Hen and Pullet classes were again weak in numbers, though excellent in quality.

Polands leave nothing to be desired in merit, and they are improving in numbers, but it is slowly. Mr. Adkins's Silvers are perfect. All the Blacks were highly meritorious, especially those from Messrs. Edwards and Smith. Mrs. Pettat's and Mr. Dixon's Golden were very good. The Varieties were not very numerous. Lord Guernsey took first prize for Cuckoos; Lady Aylesford second; and Mr. Lowndes third.

The *Game* pens were as usual filled with perfect specimens in every class. While we looked at the Black Reds, we thought them best; then we were disposed to think the same of the Brown Reds, and then we altered our verdict in favour of the Duckwings. Mr. Wood's cup-pen was a perfect one; so were the prize birds of Messrs. Williams, Crnws, and Dyas. Mr. Adams's Piles also deserve every praise. Mr. Fletcher's Duckwings were very good. Seventy-two pens deserved and obtained especial mention. Messrs. Stubb, Doncaster, Billing, Swann, Garlick, Adams, and Dawson headed them. The Piles were better than common. Here the hens and pullets, although of excellent quality, were deficient in numbers. Miss Charlton's pullets were beautiful.

Eighty-eight *Single Dorking Cocks* supplied thirty-two

mentions in the Judges' awards. It is impossible to give names throughout, our limits will not permit it, but we unhesitatingly record our opinion that it was the best class ever seen. Lady Holmesdale's victory was a great one in being first. Her ladyship repeated the exploit in the next class, a very good one of Spanish. All the Single Cock classes were well filled, as the list will show. They are not only attractive, but they are convenient to purchasers. The Cochins were not behind the Dorking, nor the Brahmas inferior to the Cochins. The Hamburgs of all classes were excellent, and the Polands good. We almost think these classes contained better birds than the general ones.

The Gold-laced *Bantams* were not so good as the Silvers in markings, but they were better in combs. Several in the Silver class had imperfect ones. Mr. H. D. Bayly and Mr. Leno took all the prizes. The Black were highly meritorious—indeed, some of them were perfect. The Variety Bantams brought us a beautiful pen of Cochin Bantams, perfect in every particular; also some pretty Japanese.

This brings us to the end of the fowls, and we are glad of it.

Aylesbury Ducks did not show so numerous as we have seen. The first prize went to Mr. Smith, the three weighed 25 lbs.; second to Mrs. Seamons, 24½ lbs.; third, Mr. Fowler, 24½ lbs. It was a good class, eclipsed, however, by forty-three pens of Rouens, forming such a display of that breed as has been seldom seen. Not only were they good in colour, but they were trading on the heels of the Aylesburs in weight. Mr. H. Worrall, almost the father of the class, took first with 23 lbs., Mr. Statter second, 22½ lbs., and Mr. Shaw third, 22 lbs. It was in every respect a grand class. The Blacks were excellent; and the Various Ducks showed the beautiful Mandarin, the Brown and White Call, and the wild Duck; while the Ornamental Waterfowl showed Black Swans, Barnacle and Egyptian Geese, and Carolina Ducks.

The three first-prize *White Geese*, belonging to Mrs. Seamons, weighed 67 lbs., the second 62 lbs., the third 53 lbs. Young birds of the same breed—Mr. Fowler 52 lbs., Mr. Davies second 50 lbs. Grey and Mottled Geese afforded a triumph to Mrs. Fergusson Blair: that lady took first, 77 lbs.; Mr. Fowler second, 75 lbs.; and Mrs. Blair third, 70 lbs. In the younger birds the first prize weighed 63 lbs., the second 57 lbs.

The *Turkeys* were excellent. Our remarks have been so long that we shall be obliged to dismiss them with short notice, merely giving their weights, and remarking that Mr. Guy took three out of six prizes, Mrs. F. Blair one, and Mr. Smith two. The weights of the adults were 65 lbs., 61 lbs., and 58 lbs.; of young birds, 58 lbs., 45 lbs., and 44 lbs. It was remarked that no American Turkeys were shown.

Thus ended the greatest Show ever yet seen. The admissions on the first day were two thousand more than on the same day in the preceding year. The sales of poultry increased in like manner, £650 were taken on the first day.

It is unnecessary to add that every one was at his post; that the Committee were indefatigable; and that everything was done that could add to the pleasure or comfort of the visitors.

We gave a list of the prizetakers last week, and now append the commendations.

DORKING (Coloured).—Highly Commended, Rev. J. G. A. Baker, Old Warden Vicarage, Biggleswade, Bedfordshire; G. C. Whitwell, Tolson Hall, Kendal (Grey); W. H. Denison, Hardwicke Cottage, Woburn, Bedfordshire; J. Drewry, Newton Mount, Burton-upon-Trent. Commended, J. K. Fowler, Aylesbury. **Chickens.**—Highly Commended, Mrs. Arkwright, Etwell Hall, Derby; Right Hon. Viscountess Holmesdale, Linton Park, Staplehurst, Kent; Captain W. Hornby, R.N., Knowsley Cottage, Prescott; Rev. J. F. Newton, Kirby-in-Cleveland, Stokesley, Yorkshire; Sir St. G. Gore, Bart., Hopton Hall, Wirksworth, Derbyshire; Sir J. D. Wauchop, Newton House, Millerhill, Dalkeith, N.B.; Rev. T. O'Grady, Hognaston Vicarage, Ashbourne (Silver Grey); W. Dolby, Horse Grove, Rotherfield, Tunbridge Wells; A. Potts, Hoole Hall, Chester; C. H. Wakefield, Malvern Wells. Commended, H. Savile, Manor Farm, Rufford Abbey, Orleton, Nottinghamshire; Right Hon. Viscountess Holmesdale; Mrs. Arkwright; Rev. J. F. Newton; W. Dolby; J. D. Hewson, M.D., Coton Hill, Stafford; J. Drewry.

DORKING HENS.—Highly Commended, Mrs. F. Blair, Balthayock, Inchmartine, Inchture, N.B.; J. Hill, Bladen Castle, Burton-upon-Trent. Commended, Rev. J. F. Newton, Kirby-in-Cleveland, Stokesley, Yorkshire; Mrs. G. H. Cook, Hartford Hall, Northwich, Cheshire (Grey); J. D. Hewson, M.D., Coton Hall, Stafford (Coloured). **Pullets.**—Highly Commended, Right Hon. Viscountess Holmesdale, Linton Park, Staplehurst, Kent; Lady Sophia Des Vaux, Drakelow Hall, Burton-upon-Trent; Captain W. Hornby, R.N., Knowsley Cottage, Prescott; Sir H. Des Vaux, Bart., Drakelow Hall, Burton-upon-Trent; Rev. J. G. A. Baker, Old Warden Vicarage, Biggleswade, Bedfordshire (Coloured); Mrs. Young, Easington Vicarage, Stratford-upon-Avon (Coloured); C. H. Wakefield,

Malvern Wells (Coloured). Commended, Mrs. Seamons, Hartwell, Aylesbury (Silver Grey).

SPANISH.—Highly Commended, J. Garlick, West Derby Road, Liverpool. *Chickens.*—Highly Commended, Miss E. Eggar, Nethermill, Moffat, Dumfriesshire; J. Smith, Little London Farm, Hillingdon, Middlesex; R. W. Boyle, Rosemount, Dundrod, County Dublin; J. R. Rodbar, Aldwick Court, Winton, Bristol; J. Garlick. Commended, W. R. Bull, Newport Pagnell, Buckinghamshire.

SPANISH HENS.—Highly Commended, Right Hon. Viscountess Holmesdale, Linton Park, Kent; E. T. Holden, Walsall.

COCHIN-CHINA (Cinnamon and Buff).—Highly Commended, E. Musgrove, Aughton, near Ormskirk; G. Fell, Warrington; H. Bates, Harborne Heath Cottage, Birmingham. Commended, D. Causar, Orcott Villa, Erdington, near Birmingham; T. Stretch, Ormskirk; H. Bates. *Chickens.*—Highly Commended, Right Hon. Viscountess Holmesdale, Linton Park, Kent; T. Stretch, Ormskirk; C. Felton, Erdington, near Birmingham; C. T. Bishop, Lenton, near Nottingham; Captain Beaton, Lower Broughton, Manchester. Commended, Mrs. White, Broomhall Park, Sheffield.

COCHIN-CHINA HENS (Cinnamon and Buff).—Highly Commended, Mrs. White, Broomhall Park, Sheffield; D. Young, Radford Villa, Leamington; J. Shortrose, Sheffield Green, Newcastle-upon-Tyne; C. T. Bishop, Lenton, near Nottingham. Commended, Captain Beaton, Lower Broughton, Manchester; C. Felton, Erdington, near Birmingham. *Pullets.*—Highly Commended, Rev. G. Gilbert, Claxton, Norwich. Commended, C. Felton, Erdington, near Birmingham; Captain Beaton, Lower Broughton, Manchester; Rev. G. Gilbert.

COCHIN-CHINA (Brown and Partridge-feathered).—*Chickens.*—Highly Commended, E. Adams, Harborne Heath, Birmingham. Commended, Cartwright, Oswestry.

COCHIN-CHINA HENS (Brown and Partridge-feathered).—Highly Commended, Cartwright, Oswestry. Commended, J. Shortrose, Newcastle-upon-Tyne.

COCHIN-CHINA (White).—Highly Commended, R. Chase, Birmingham. Commended, D. Causar, Birmingham. *Chickens.*—Highly Commended, F. W. Zuhorst, Donnybrook, Dublin. Commended, Right Hon. Viscountess Holmesdale, Linton Park, Kent.

BRAHMA POOTRA.—Highly Commended, R. Adams, Birmingham; E. Tebbay, Fulwood, Preston. *Chickens.*—Highly Commended, Mrs. Hargreaves, Reading (Dark); R. Tebbay, Fulwood, Preston; J. K. Fowler, Aylesbury; W. L. Barclay, Leyton, London, N.E. (Dark); T. Pountner, Preston. Commended, J. Pares, Chertsey (Light); Mrs. F. Blair, Inchmartine, Inchture, N.B.

MALAY.—Highly Commended, Miss C. H. Ballance, Taunton. *Chickens.*—Highly Commended, Miss C. H. Ballance; E. Leech, Rochdale; Master C. A. Ballance, Taunton.

CRÈVE CŒUR.—*Chickens.*—Commended, Mrs. F. Blair, Inchmartine, Inchture, N.B.

HAMBERG (Black).—Highly Commended, J. Dixon, Bradford. *Chickens.*—Highly Commended, E. Freer, Castle Bromwich, Birmingham; S. Shaw, Stainland, Halifax; F. Sabin, Birmingham; E. Smith, Middleton, Manchester. Commended, R. H. Nicholas, Malpas, Newport, Mounmouthshire; W. W. Nicholls, Sale, Manchester.

HAMBERG (Golden-pencilled).—Commended, J. Robinson, Garstang. *Chickens.*—Highly Commended, J. Mann, Newchurch, Manchester; Messrs. Carter & Valiant, Ponton-le-Fylde, Lancashire; T. Craven, Bradford. Commended, J. Mann.

HAMBERG (Silver-pencilled).—*Chickens.*—Highly Commended, Right Hon. Viscountess Holmesdale, Linton Park, Kent.

HAMBERG (Pencilled).—*Pullets.*—Highly Commended, Mrs. W. Kershaw, Heywood, Manchester (Golden); J. Mann, Newchurch, Manchester (Golden).

HAMBERG (Golden-spangled).—Highly Commended, J. Dixon, Bradford. Commended, W. Kershaw, Manchester; H. Carter, Holmthorpe, Yorkshire. *Chickens.*—W. W. Nicholls, Sale, Manchester; Messrs. Broadhead, Hepworth & Coldwell, Holmthorpe, Yorkshire. Commended, N. Maitor, Denton, Manchester; H. Carter, Holmthorpe.

HAMBERG (Silver-spangled).—Highly Commended, J. Fielding, Newchurch, Manchester; Mrs. Pettat, Easingstone. Commended, H. Beldon, Bingley. *Chickens.*—Highly Commended, W. Cannon, Bradford; G. E. Hardman, Raxt-on-stall, Manchester; Mrs. Pettat.

HAMBERG HENS (Spangled).—Highly Commended, H. W. B. Berwick, Helmsley, Yorkshire (Golden); H. Beldon, Bingley; J. Ellis, Kirkcaldy, Leeds (Golden).

POLISH (Black and White Crests).—*Chickens.*—Highly Commended, E. Smith, Middleton, Manchester.

POLISH (Golden).—Highly Commended, Mrs. F. Blair, Balthayock.

POLISH (Silver).—Highly Commended, J. Dixon, Bradford. Commended, W. Newsome, Bingley. *Chickens.*—Highly Commended, G. C. Atkins, Birmingham.

ANY OTHER DISTINCT VARIETY.—Highly Commended, R. H. Nicholas, Newport (Chinese Silky); Mrs. F. Blair, Balthayock (La Flèche). Commended, Right Hon. Countess of Aylesford, Leamington Spa (Cuckoo Dorking); Right Hon. Lord Guernsey, Leamington (Cuckoo Dorking).

GAME (Black-breasted Reds).—*Chickens.*—Highly Commended, R. Woods, Workop. Commended, W. Cox, Derby; H. M. Julian, Beverley; M. Billing, jun., Birmingham; J. Holme, Knowsley, Prescott.

GAME (Brown and other Reds, except Black-breasted).—Highly Commended, M. Billing, jun., Birmingham; E. Burton, Turro, R. Swift, Southwell; H. Adams, Beverley. Commended, T. Statter, Manchester. *Chickens.*—Highly Commended, H. Snowden, Bradford; G. Clements, Birmingham; W. J. Cope, Batusley.

GAME HENS (Black-breasted and other Reds).—Highly Commended, J. Wood, Wigan (Brown Red). *Pullets.*—Highly Commended, J. Stubbs, Stafford (Black Red); R. Adcock, Shuteoke (Brown Red); W. H. Denison, Bedfordshire (Brown Red); J. Wood (Black Red); R. Parkinson, Lancashire (Black Red); J. H. Braikenridge, Bristol.

GAME (Duckwings, and other Greys and Blues).—Highly Commended, E. C. Gilbert, Penkridge. Commended, J. Doncaster, Lincolnshire. *Chickens.*—Highly Commended, J. Wood, Wigan; J. Doncaster, Lincoln.

GAME (White and Pile).—*Chickens.*—Highly Commended, Rev. G. S. Craws, Tiverton (Pile); J. Fletcher, Stoneclough (Pile); A. Guy, Eaton, Grantham (Pile); F. A. Britherton, Lancashire (Pile).

CLASSES FOR SINGLE COCKS.

DORKING.—Highly Commended, Lady S. Des Vaux, Burton-upon-Trent; Sir H. Des Vaux, Bath, Burton-upon-Trent; Mrs. F. Blair,

Balthayock; Miss Wilcox, Bristol (Grey); Right Hon. Viscountess Holmesdale, Linton Park, Kent; Rev. M. Auplett, Evesham; Rev. T. O'Grady, Ashbourne; J. D. Hewson, M.D., Stafford; Mrs. Kothery, Haslemere, Surrey; Miss J. Milward, Somersetshire; W. Dolby, Tunbridge Wells; Rev. J. G. A. Baker, Biggleswade, Beds; J. Drewry, Burton-upon-Trent; Rev. E. Cadogan, Warwick; Sir J. D. Waushope, Dalketh, N.B.; E. Tudman, Whitchurch; J. Robinson, Garstang; J. Hill, Burton-upon-Trent; E. Shaw, Oswestry (Grey); H. B. Lee, Bewdley. Commended, Rev. E. Cadogan; J. Smith, Henley-in-Arden.

SPANISH.—Highly Commended, J. L. Lowndes, Aylesbury; H. Lane, Bristol; J. Garlick, Liverpool; R. Paton, Kilhamock, Ayrshire. Commended, W. R. Bull, Newport; J. W. Smith, Oundle; T. Tatham, Kings Thorpe.

COCHIN-CHINA (Cinnamon and Buff).—Highly Commended, F. M. Hiddle, Lancashire. Commended, Mrs. White, Sheffield; J. Stephens, Walsall; C. T. Bishop, Nottingham.

COCHIN-CHINA (Except Cinnamon and Buff).—Highly Commended, R. Adams, Birmingham (Partridge); C. Felton, Birmingham (Partridge); G. Williams, Oswestry (Partridge).

BRAHMA POOTRA.—Highly Commended, Mrs. Hargreaves, Reading (Dark); J. Pares, Chertsey (Light); R. Tebbay, Preston.

HAMBERG (Golden-pencilled).—Highly Commended, Hon. J. F. Clifford-Butler, Abereavny; J. Choyce, Atherton; Mrs. W. Kershaw, Heywood; H. Beldon, Bingley.

HAMBERG (Silver-pencilled).—Highly Commended, Right Hon. Viscountess Holmesdale, Linton Park, Kent; C. M. Roys, Rochdale; H. Beldon, Bingley; J. Bennett, Gloucestershire. Commended, D. Harding, Middlewich.

HAMBERG (Golden-spangled).—Highly Commended, H. E. Emberlin, Leicester. Commended, G. Lugard, jun., Birmingham; H. Beldon, Bingley.

HAMBERG (Silver-spangled).—Highly Commended, Mrs. Wolferstan, Tamworth; J. Fielding, Newchurch; H. Beldon, Bingley.

POLISH.—Highly Commended, Mrs. Letat, Asbe Rectory, Easingstone (Golden).

GAME (White and Pile, Duckwings and other varieties, except Reds).—Highly Commended, E. C. Gilbert, Penkridge (Spangled); T. Carless, Nottingham (Duckwing); J. Fletcher, Stoneclough, Manchester (Duckwing).

GAME (Black-breasted Reds).—Highly Commended, Sir St. G. Gore, Bart., Derbyshire; G. Wostenholm, Sheffield; J. Fletcher, Stoneclough; R. Woods, Osberton; E. C. Gilbert, Penkridge; S. Mathew, Stowmarket. Commended, G. Wostenholm, Sheffield.

GAME (Brown and other Reds, except Black-breasted).—Highly Commended, G. Clements, Birmingham; H. Adams, Beverley; R. Swift, Southwell; N. Grimshaw, Lancashire; T. Statter, Manchester. Commended, J. Wood, Wigan.

BANTAMS (Gold-laced).—Highly Commended, Rev. G. S. Craws, Tiverton.

BANTAMS (Silver-laced).—Commended, Rev. G. S. Craws, Tiverton.

BANTAMS (White Clean-legged).—Highly Commended, Captain Wetherall, Loddington, Northamptonshire.

BANTAMS (Black Clean-legged).—Highly Commended, W. Cannon, Bradford; R. Brotherhood, jun., Chippenham. Commended, Miss P. Ridgway, Dewsbury.

GAME BANTAM COCKS.—Highly Commended, Miss Crawford, Southwell; T. H. D. Bayley, Biggleswade; W. R. Lane, Birmingham; Mrs. J. Mann, Newchurch. Commended, F. Esquilant, London; H. Sheild, Northampton.

DUCKS (White Aylesbury).—Highly Commended, Sir St. G. Gore, Bart., Derbyshire; Mrs. Kothery, Haslemere; E. Leech, Rochdale; Mrs. Saunons, Aylesbury. Commended, Messrs. Broadhead, Hepworth & Coldwell, Holmthorpe; R. H. Nicholas, Newport.

DUCKS (Konen).—Highly Commended, Sir St. G. Gore, Bart., Derbyshire; Mrs. F. Blair, Balthayock, N.B.; T. R. Hubert, Gloucester; W. Gamon, Thornton-le-Moors; T. Robinson, Ulvestone; H. Worrall, West Derby. Commended, W. H. Denison, Bedfordshire; R. W. Boyle, Rosemount, Dublin; T. Statter, Manchester; T. Robinson, Ulvestone.

DUCKS (Black East Indian).—Highly Commended, F. W. Earle, Prescott; J. W. Smith, Oundle. Commended, Mrs. Wolferstan, Tamworth.

DUCKS (Any other variety).—Highly Commended, J. Dixon, Bradford (Grey Call); S. Shaw, Halifax (Mandarin); G. Williams, Oswestry (White Call).

GREYS (White).—Highly Commended, J. Faulkner, Burton-upon-Trent. *Goslings.*—Highly Commended, W. Winterton, Hincley (Improved English).

GREYS (Grey and Mottled).—Highly Commended, J. Dixon, Bradford; D. R. Davies, Cusheire. *Goslings.*—Highly Commended, J. K. Fowler, Aylesbury (Toulouse).

TUCKERS.—Highly Commended, J. Coxon, Lichfield (Cambridgeshire); J. Smith, Grantham (Cambridgeshire). *Poult.*—Highly Commended, Right Hon. Lord Stanhope, Burton-upon-Trent (Dark); Mrs. Wolferstan, Tamworth (Cambridgeshire); Rev. T. L. Fellowes, Norfolk (Cambridgeshire); W. Winterton, Hincley (Cambridgeshire); J. W. Smith, Oundle (Cambridgeshire).

The Judges were the Rev. R. Pallen, Kirby Wiske, Thirsk; G. J. Andrews, Esq., Dorchester; J. H. Smith, Esq., Skelton Grange, York; J. Hindson, Esq., Barton House, Everton, Liverpool; and Mr. Bailly, London.

PIGEONS.

THE Pigeons were principally ranged in one of the galleries, and formed an excellent collection.

Among *Tumblers* were first in the list, with a very keen competition, more especially between Mr. Else and Mr. Eden for first and second positions. Mr. Stuart, of Glasgow took third with a good pen, the cock being rather dark.

In *Carrier* cocks (Black) Mr. Eden's first and second prize birds were excellent. In hens of the same colour the competition was close, and the first-prize bird belonging to

Messrs. Siddons was claimed at £10 10s. Mr. Else's second-prize hen merited her position. In both classes for Carriers of any other colour, single birds, Mr. Eden and Mr. Colley, of Sheffield took all the prizes with capital Duns, the former gaining both first prizes.

In *Powder cocks*, Red or Blue, the prizes went to fine lengthy Blues belonging to Mr. Fulton; while in hens of the same colour Mr. Eden was first with Blue, and Mr. Potts second with a good Red. In *Powder cocks*, Any other colour, Mr. Eden's famed White was first, Mr. Fulton being second with a good representative in a slaty Black; and in hens, Any other colour, the same exhibitors reversed their positions, with birds of precisely the same colours.

Balds and *Beards* formed two fair classes. Many of the birds, however, were rather defective in eye.

Mottled *Tumblers* were good, more particularly the first-prize Black Mottles. *Tumblers*, Any other colour, were an average lot.

Silver Runts took both prizes in the class allotted to them.

There was a good show of Red or Yellow *Jacobins*, Mr. Lawrence's first-prize Yellows being excellent. Mr. Esquilant's Reds were also good. In *Jacobins*, Any other colour, good Blacks were first, and Whites second.

White *Fantails* formed a large class, both prizes being awarded to Crested birds. In *Fantails*, Any other colour, Blues were first and Blacks second.

Trumpeters were divided into two classes—Mottled, and Any other colour. In the former class Mr. Shaw's extraordinary pair again stood clear of everything, this being the fifth successive year in which they have taken first prize at Birmingham—viz., twice when sent by their former owner, Mr. Mewburn, of Darlington, and twice by Mr. Shaw, a fact we believe never achieved by any other pair of Pigeons; and well they deserve their honours. In the latter class Mr. Oakes's capital Whites were first, and Mr. Shaw second with exceedingly good Blacks.

The *Owl* classes were, perhaps, inferior to none. That for Blue or Silver, although not very large, contained good birds, foreign Blues winning. In *Owls*, Any other colour, the collection of seventeen pens was characterised by the Judges as "a beautiful class." They were principally the small Whites, both prizes being awarded to splendid Whites. One of the birds in the first-prize pen was rather out of condition. The second were remarkably good young birds, and speedily changed ownership.

Nuns were a fair class, Black-headed taking the prizes.

Turbits were divided into Red or Blue, and Any other colour. Red took both prizes in the former, and Yellows in the latter. Mr. Shaw had both first prizes with excellent shell-crowned birds, while the second Reds were point-headed. A plain-headed yellow-barred pair received high commendation. Some good Blues and Silver were also exhibited.

Black *Barbs* only numbered two entries, and do not require especial notice. *Barbs*, Any other colour, were better represented. Mr. Eden's admirable Yellows were first, Mr. Stuart second with Reds, the hen rather thin, and long in beak, while Mr. Lawrence received high commendation for two good pens of rather young Yellows.

Dragoons, *Maggies*, and *Antwerps* were average classes.

In Any other new or distinct variety, *Satinettes* were first, *Swiss* second, and *Black-tailed Owls* third, notwithstanding the two classes for *Owls*—viz., Blue or Silver, and Any other colour, the latter containing *Black-tailed Owls*.

It is rather difficult to understand how they can be called Any other new or distinct variety merely from having black tails, a variation in the colour of any part of the feather, it would seem, taking them out of the category of *Owls*, the properties of which they possess. We believe the same exhibitor won with the same or similar birds at Collingham a short time since in a like class, and as it places exhibitors in a dilemma the point should be settled whether they are correctly classified or not.

In addition to the prizes given last week, the following are the commendations:—

CARRIER (Black).—Commended, E. Snow, jun., Birmingham; Messrs. W. Siddons & Sons, Aston. *Hen*.—Very Highly Commended, P. Eden, Salford. Highly Commended, E. Snow, jun., Birmingham.

CARRIER (Any other colour).—Commended, T. Colley, Sheffield (Dun).

POWTER (Red or Blue).—Very Highly Commended, M. Stuart, Glasgow.

POWTER (Any other colour).—Very Highly Commended, M. Stuart, Glasgow (Black). Commended, P. Eden, Salford.

BALDS.—Highly Commended, W. Woodhouse, Lynn, Norfolk (Black). Commended, W. Woodhouse (Dun).

BEARDS.—Commended, J. Fielding jun., Rochdale (Short-faced).

TUMBLERS (Any other colour, except Mottled).—Highly Commended, F. Esquilant, London (Yellow).

JACOBI (Red or Yellow).—Highly Commended, J. T. Lawrence, Everton. Commended, H. Morris, Kent.

FANTAILS (White).—Commended, G. H. Sanday, Pierrepont; M. E. Jolting, Newcastle-upon-Tyne; F. Else, Bayswater.

TRUMPETERS (Any other colour, except Mottled).—Highly Commended, W. H. Denison, Woburn (Black). Commended, J. Bailly, jun., London, W. (Imported).

OWLS (Any other colour, except Blue or Silver).—Very Highly Commended, F. Else, Bayswater. Commended, Mrs. J. Bailly, jun., London, W. (Imported).

NUNS.—Highly Commended, T. Ridpath, Rusholme. Commended, H. Yardley, Birmingham; F. Else, Bayswater.

TURBITS (Red or Blue).—Highly Commended, S. Shaw, Stainland.

TURBITS (Any other colour).—Highly Commended, F. H. Paget, Birstall (Silver); H. Yardley, Birmingham; F. Else, Bayswater.

BARBS (Any other colour, except Black).—Highly Commended, J. T. Lawrence, Everton.

DRAGOONS.—Highly Commended, T. Ridpath, Rusholme. Commended, J. Heape, Birmingham; F. Else, Bayswater.

ANY OTHER NEW OR DISTINCT VARIETY.—Highly Commended, H. Yardley, Birmingham. Commended, S. Shaw, Stainland.

BRIGHTON POULTRY EXHIBITION.

This Show has proved itself a great success, it being held just at the height of the Brighton season, and, consequently, when it was most thronged with fashionable visitors. Although taking place in the very midst of the great Poultry Show week at Birmingham, it appears Brighton is too far removed from the inland counties to suffer materially from that circumstance, although it has not unfrequently in other places proved too truly that to hold a show at the Birmingham time risks most materially its success. At Brighton, on the contrary, many of the classes were quite as well filled as we find to be the case at the great majority of our poultry shows.

Through the kind and willing assistance of the Brighton Railway Company the poultry were exhibited in one of the station buildings, than which, for such a purpose, we can hardly call to mind one more suitable. Were such an object desired, this building might be made to hold even a couple of thousand pens commodiously. The light throughout is equal to that of the open air, whilst it is comfortably secure on all sides from every possible casualty of weather. The good result of such being the case could hardly be more strongly manifested than on this very occasion; for on the morning of the Show's opening, as is too well known throughout the land, a gale of unprecedented severity occurred, accompanied by driving rain, which it is impossible to describe as it proved to endure. Still, within the building everything was as comfortable and happy as could be desired. Most luckily, just prior to the hour of opening, the rain ceased entirely, the gale abated to a health-giving breeze, and thus visitors were enabled to enjoy the Exhibition without discomfort of any kind.

The Grey *Dorkings* were certainly one of the chief features of the Brighton Show. They were almost all of high character; the Marchioness Dowager of Bath, and Mr. Wm. Dolby, of Rotherfield, taking the principal prizes with specimens of great merit. In the *Game* classes there were individual birds of high quality; but as being only the second meeting of this Society, of course the art of properly matching their birds did not seem at all understood by the Game-exhibitors. Black-breasted Red hens were shown with Duckwing cocks; Birchen Greys were exhibited with hens of plumage that certainly would not match the feather of any Game cock we ever yet met with, whilst being still in very heavy moult told unfortunately on not a few others. Experience will soon correct these shortcomings another season. The Black *Spanish* fowls were better by far than we anticipated seeing at Brighton, though more than half of them lacked that great feature so very important to success—viz., condition. Perhaps no breed shows to so great a disadvantage as the Spanish when lacking this needful qualification. The Pencilled varieties of *Hamburghs* were the only breeds to which prizes were given; the equally useful and beautiful varieties of Spangled ones being omitted from the prize list altogether. In the Gold-pencilled a quite new name as an exhibitor—Mr. Francis Pittis, of Newport House, Isle of Wight—took all before him; in fact, that gentleman obtained all three prizes by a mere "walk over."

In the *Poland* class, open to all breeds, Mr. Panton Edwards, of Lyndhurst, stood first and third with his Black White-crested ones, whose notoriety is become proverbial. Mr. Joseph Hinton, of Bath, however, showed some most excellent Silver-spangled *Polands*, taking second place. The *Bantams* were mostly good; Mr. Kelleway, of the Isle of Wight, taking the lead with a pen of capital Black-breasted Red Game, that evidently were not improved by having been over-exhibited. Some White-booted *Bantams*, and some Grey Game *Bantams*, were also exceedingly well shown.

To say that Mrs. Mary Seamons, of Aylesbury, won all the prizes for Aylesbury *Ducks* is so oft-told in our descriptions of poultry meetings, that it begins to suggest itself to compositors to always keep the announcement ready in type, as being always wanted when this lady exhibits. Her rivals were of great excellence also, hence the high commendations of others. In *Geese* and *Turkeys*, also, Mr. Dolby, of Rotherfield, had it all his own way, his pens of these birds being of the highest merit.

Pigeons were only blessed at Brighton with a single general class for all breeds; hence came a medley contest. Nevertheless they proved a capital addition to the Show, bringing birds together of no mean pretensions; and on future occasions the Committee, we trust, will feel themselves justified in a considerably extended Pigeon prize schedule.

In Extra Stock it is seldom that a better class is seen; but on this occasion, of course, they received no premiums. This class comprised, besides excellent Silver-spangled *Hamburghs*, beautiful dark *Brahmas*, and not less worthy *Silky fowls*, some very well-shown *Peafowls*, and a couple of brace of the Ring-necked Pheasant in excellent feather.

DORRINGS.—First and Second, W. Dolby, Horse Grove, Rotherfield, Third, Marchioness Dowager of Bath, Muntham Court. Highly Commended, W. Stanford, jun., Court Farm, Steyning. *Chickens.*—First, Second, and Third, Marchioness Dowager of Bath. Highly Commended, C. Cork, New Shoreham; W. R. Seymour, Crowood, Hungerford. Commended, W. Dolby.

GAME.—First, G. Boniface, jun., Ford, Arundel. Second, S. Ridley, Clayton, Sussex. Third, Rev. F. B. Parkes, Southwick Rectory. Commended, H. Gorringe, Southwick Green, near Shoreham. *Chickens.*—First and Third, G. Boniface, jun., Ford, Arundel. Second, G. W. Ranwell, Kingston Crescent, Portsea, Hants. Commended, S. Ridley, Clayton.

SPANISH.—First, A. E. Smith, Wish Street, Southsea, Hants. Second, J. H. A. Jenner, East Street, Lewes. Third, W. R. Bull, Arundel. Commended, Rev. J. de la S. Simmonds, Chilcomb Rectory, Winchester. *Chickens.*—First, C. Cayford, Waterloo Street, Brighton. Second, W. R. Bull, Arundel, Sussex. Equal Second, Rev. J. de la S. Simmonds.

POLANDS (Any variety).—First and Third, T. P. Edwards, Lyndhurst, Hants (Black with White Crests). Second, J. Hinton, Hinton, near Bath (Silver-spangled *Polands*). Highly Commended, F. Phillips.

HAMBURGH (Gold-pencilled).—First, Second, and Third, P. Pittis, jun., Newport House, Newport, Isle of Wight.

HAVENRICH (Silver-pencilled).—First, B. W. Saunders, St. James's Street, Second, T. Boniface, Ford, Arundel. Third, Marchioness Dowager of Bath.

BANTAMS (Any variety).—First, J. W. Kelleway, Merston, Isle of Wight (Black-breasted Red Game *Bantams*). Second, W. S. Forrest, Eagle Cliffe, Greenhithe, Kent (Grey Game *Bantams*). Third, F. H. Phillips, Chippenharn, Wilts (White-booted *Bantams*). Highly Commended, C. Nicholson, Portland Street, Fareham (Red Pile Game *Bantams*). Commended, P. Pittis, jun., Newport, Isle of Wight (Blacks); S. Ridley, Clayton, Sussex (White *Bantams*).

SWEPESTAKES FOR SINGLE COCKS.

DORRING.—First, F. Stanford, Lancing, Shetchem. Second, Marchioness Dowager of Bath. Commended, C. Cork.

GAME.—First, G. Boniface, jun., Ford, Arundel. Second, H. Gorringe, Southwick Green.

GESE.—First, W. Dolby, Horse Grove, Rotherfield (Toulouse *Geese*). Second, G. Hudson, Cooksbridge, Hamsey, Sussex (a mixed variety).

DUCKS (Aylesbury).—First and Second, Mrs. M. Seamons, Hattwell, Aylesbury, Bucks. Highly Commended, Marchioness Dowager of Bath, Muntham Court; W. Dolby, Horse Grove, Rotherfield.

DUCKS (Any variety).—First, J. Adams, Red Barn Farm, Farnham (Rouen *Ducks*). Second, H. Peters, Halfway House, Dyke Road (Buenos Ayrean). Commended, Marchioness Dowager of Bath (Rouen *Ducks*).

TURKEYS.—First, W. Dolby. Second, G. Hudson, Cooksbridge, Hamsey.

PIGEONS (Any variety).—First, H. Bunce, Queen's Terrace, Brunswick Road, Walworth (Black Mottled *Pigeons*). Second, E. S. Parkinson, Old Steine, Brighton (Black Carriers). Third, C. H. Matthews, Patcham (White Runts). Highly Commended, Gearing, Brighton (Black Runts); C. Cork, New Shoreham (Blue Horsemen); T. Duddleston, Termisus Place, Brighton (Almond Tumblers); W. H. Fry, London Road, Brighton (White Horsemen). Commended, J. Percival, Montpellier Road, Rye Lane, Peckham (Toys); C. Cork, New Shoreham (Blue Horsemen).

The Judges were Mr. James Singer Turner, of Chyngton, Seaford, Sussex; and Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, near Birmingham.

BEEES GATHERING POLLEN IN NOVEMBER.

I OBSERVED these indefatigable workers, from three straw hives in the gardens of this place, uncommonly busy pollen-gathering as late as yesterday (November 26). The day was

mild but sunless, as it generally is here. They kept hard at work as late as three o'clock in the afternoon—in fact, for the past three weeks they have not been idle. For some time I was puzzled to find out from what flowers they succeeded in obtaining such a quantity of pollen at this season, few flowers either in the garden, field, or woods, being in bloom now; but on watching them I discovered the source. It was the ivy, which is just in flower, and of which there is an immense quantity in the woods, clinging round half the forest trees to the height of from 20 to 30 feet. Probably the bees of some of your correspondents gather pollen from the same source.—JOHN EDLINGTON, *Crom Castle, Ireland.*

FOUL BROOD.

IN Mr. Lowe's article in page 444, after declaring that his thoughts are "turned on peace," he nevertheless does not hesitate to stigmatise "B. & W.'s" gentleman-like and straightforward remonstrance in page 364, as a "warlike article," in which the writer has "completely exhausted his fire and fury," and at the same time seems to warn Mr. Edwards that he has a rod in pickle for him at some future time. Surely even Mr. Lowe must be aware that misdescription and hard words on his part only add to the force and justice of "B. & W.'s" protest, whilst I am much mistaken if Mr. Edwards be the man to cower under his implied threat. The passage addressed to myself I dismiss without comment.

Before, however, Mr. Lowe again launches forth into the general question of foul brood, I take leave to draw his attention to a few of his statements which have already been completely disproved by the most conclusive evidence. When he starts on his expedition which is to culminate in the universal acceptance of certain peculiar doctrines, which he naively declares to be in opposition to those of the most skilled apirians of the day, both English and foreign, it is very possible that I for one may decline to accompany him, unless in the meantime he shows a greater disposition than he has hitherto done to discuss the matter in a fair and candid spirit, and lay aside the habit of carefully ignoring all evidence and facts which militate against his own theories and opinions. I will, therefore, recall a few of his fallacies, and the evidence by which they have been demolished.

1st. It is only in the hands of the experimentalist that we find its presence (foul brood) generally manifested. Disproved by Mr. Shearer's narrative in page 182, the evidence of the "STEWARTON APIARIAN," in page 243, and the experience of Mr. Quinby, recited in page 158.

2nd. Excision of the affected parts is sufficient for the cure of foul brood. Completely disproved by Mr. Shearer, in page 182, and by my own experience, related in page 78.

3rd. Chilled brood is not removed by bees. Utterly disproved by my experiment described in page 342, by the evidence of "B. & W." Mr. Shearer, Mr. Edwards, and many others, as well as by the observation of every bee-keeper who has noticed the fact of chilled larvae being dragged out of bee-hives in spring.—A DEVONSHIRE BEE-KEEPER.

OUR LETTER BOX.

WHITE BANTAMS (J. G.).—Rose combs are more highly considered than single combs. It is not indispensable that they should have white legs, but dark legs are a disadvantage. Neither a single comb nor a blue leg is a disqualification.

FOWLS FALLING SICK (A Subscriber, Wotton).—It is bad for fowls to roost too thickly in a house, but it would hardly account for the constant sickness you describe. What is the flooring? If stone, brick, or board, that is the cause of much sickness. Your feeding is good. Remove the flooring if it is objectionable. Give the birds plenty of bread and ale. Feed in the morning on ground oats, at midday on barley, and in the evening on meal again. Give bread and ale at intermediate times. Feed often and sparingly, always remove diseased birds, and keep them separate.

DETECTING LEAD IN WATER (W. H. B.).—Chromate of potash causes a canary-yellow precipitate from water containing lead in solution, and sulphate of soda causes a white precipitate. If we had a lead cistern we should sell it and replace it by a slate cistern. All household queries are willingly answered in this section of our columns. We do not purpose to divide our columns in the mode you allude to.

SAFETY OF CHASE'S BEETLE POISON (M. D.).—We have reason for believing that this is not liable to ignite. Whether the pills will inflame by friction any one may prove by rubbing one of them against a hard substance. We have seen a note from Capt. N. Marder, commander of the ship *Agamemnon*, stating that this poison is a most effectual destroyer of cockroaches, mice, and rats, "and it may be placed in all parts of a ship with perfect safety."

From observations taken near London during the last thirty-six years, the average day temperature of the week is 44.9°, and its night temperature 33.8°. The greatest heat was 56°, on the 16th, 1849; and the lowest cold, 7°, on the 16th, 1853, and 19th, 1859. The greatest fall of rain was 0.76 inch.

PEACHES UNDER GLASS AND ON THE OPEN WALL.

UCH interesting discussion has recently taken place, from both scientific and practical points of view, concerning the relative merit of Peaches as to colour and flavour when grown under glass, and on

open walls. If the colour and flavour were the only points to be taken into consideration in the erection of orchard-houses or glass screens, the advocates of such erections would certainly not lose such a great deal of all by following the course preferred by those who object to glass, and contend that fruit from the open wall is the best. No doubt, in some localities, and with favourable autumns, Peaches from the open wall may be produced higher in both colour and flavour than others to which the protection of glass has been applied. Nevertheless, a question may be raised as to the propriety of a certain class of favourably-situated cultivators laying such a result down as a rule to be followed by another, and, I suspect, a large class, very differently situated, and who are rather inclined to question the wisdom of saying that it is all moonshine to think that regular and fine crops cannot be counted on for years in succession without the protection of glass. To single out the results of a few favoured localities, and lay them down as a rule to be relied upon by all, is not the most conclusive way of establishing any theory or argument however favourable the premises may be granted to be.

What say those who are cultivating the Peach both under glass and on the open walls, or those who have abandoned the latter in favour of the former, in by far the majority of localities in Scotland and Ireland, and in many districts in England as well? Under which of the two systems have they produced the most abundant crops with regularity year after year, and with least anxiety and trouble? By which of the two systems have the best-flavoured fruit been produced? It would be very interesting and instructive if all the gardeners in the kingdom could be induced to hand in statistics bearing upon this matter, and it would be very much more decisive than any amount of argument that can be advanced, favourable or unfavourable, by a few isolated individuals.

Taking a survey of this district, which is one of the most highly favoured to be met with in Scotland, while the more immediate locality from which I write is considered to have a less rainfall than any other in the kingdom, and it has a fine loamy soil, yet there is not a

garden in it with which I am acquainted, where under the best management crops of Peaches can at all be counted on from the open wall. A full crop once in four or five years is as much, if not more, than can be looked for, judging from past experience. Under glass crops are plentiful and good. In fact, the open-wall cultivation of the Peach is one of the most disheartening and unsatisfactory departments of many good gardens which are famed for other fine fruit on the open walls.

If we travel a little further west, and enter Midlothian, I could there point to hundreds of feet of Peach walls, upon which the trees had to struggle for an existence, to say nothing of the quantity and quality of the uncertain crops, but which after being covered with glass have luxuriated and borne crops of fruit which for quantity, size, and quality, could never have been hoped for; and this, too, without any change whatever except their being covered with a light glass screen, the soil, the aspect, and the management being the very same in every respect as before they were protected with glass. There formerly was more of mildew, blister, and red spider, than anything else, and now seasons pass over without the appearance of these enemies, and a full crop of very superior fruit can annually be counted upon. If such be the results in more favoured localities, what must it be where there is less sunshine, and a greater rainfall, with late spring and earlier autumn frosts, and winter frosts much more severe? Under such circumstances it becomes not a question of a degree or two in flavour and colour, it is the chance of a crop at all; nay, in some cases, the very existence in a state to be tolerable of the Peach tree, not taking into the account the immunity from danger that occurs in severe winters, such as are occasionally experienced, and which cause serious damage to the young wood of the trees. In the winter of 1860-61, the whole of the previous summer's growth on Peaches was here cut back to the old wood, while in places where the frost was some 8° or 10° more intense, Peaches under the protection of glass screens escaped untouched. Such exemptions from injury were probably as much owing to the better-ripened state of the wood, as to the difference, if there were any difference, of temperature effected by a glass case. Last year being one of the wettest seasons which have occurred here for a good number of years, Peaches on the open walls had the most lamentable struggle which it is possible to conceive. The fruit were small and flavourless, the wood was mildewed and weak, and when pruned in December it was more like operating on Laurels than anything else, for the trees were well clad with green leaves. Under glass cases in less favoured gardens, as to soil and climate, the crop was plentiful and fine, and the wood in fine condition; and this season, although our Peach wall was covered with glass last winter when it was too late to be of any benefit to the trees, there was nothing like a full crop, but the fruit produced were vastly superior in size, colour, and flavour to any obtained from the open walls here during the last five seasons. The trees have such wood and bloom-buds as could never have been produced without glass, while

mildew and curl, formerly in abundance, never appeared, except on a young tree of the Royal Charlotte.

It is all very well to say that fine Peaches can be produced regularly on the open wall, by taking the precaution of covering when in bloom in spring. This may be applicable enough to some localities. We are bound to believe that it is from the advocates of the system, and the facts they adduce, and there is, perhaps, not much harm in their playing a tune on their own fiddle, as long as they do not insist on every person dancing to it. Assuredly it would not be the best mode in the great majority of districts in Scotland, nor in a good many in England, where I have known good gardeners give up the open-air culture of the Peach in despair, and succeed well with glass coverings. I have myself had Peaches and Apricots frosted when they were about the size of pigeon's eggs.

I cannot help thinking that where Peaches under glass in September and October are found so deficient in colour and flavour, as compared with those from the walls, there must be some disadvantage in the construction of the Peach screens, or some deficiency in their management. There are very few, if any, localities, one would suppose, where the Peach is found more healthy on the walls than under glass. This granted, we have one great fundamental condition for the production of good fruits. The want of colour and flavour has been the objection raised against glass protection. Upon what conditions do these important qualities depend? In order to answer this question satisfactorily, it is not necessary to enter into physiological arguments which have led to the conclusion which practice has attested—namely, that the flavour and colour of fruit in general, and, perhaps, Peaches in particular, depend on full exposure to light, a free circulation of dry air, with a lessened amount of moisture in the soil, and, in consequence, a higher ground temperature. These, too, are the means which produce the best ripened wood and fruit-buds—results which are unquestionably more generally obtained under glass than on the open walls. It is, therefore, somewhat singular if the same result in the ripening of the fruit, depending on the same agencies, should be wanting under glass. My own experience of the two systems has been unmistakably in favour of glass coverings. I have seen under glass Royal George and Barrington Peaches, of the darkest red, and far larger and better-flavoured than any that could be produced in the same garden without glass. These were ripened in houses constructed of large panes of the clearest sheet glass, where the whole front and top lights can be thrown so completely open as to keep every leaf and fruit in the house under a constant circulation of air. Probably the fruit loses to an injurious extent the rays of the sun by the intervention of glass; but this loss, it may be allowed, is more than counterbalanced by protection from night dews, heavy rains, wet and cooled borders, all of which must be prejudicial to high flavour. Therefore, I cannot help thinking that in by far the majority of localities there must be something amiss in the construction of the glass protection, or in the management of it, if in-door Peaches in September and October are not superior to the same varieties on the open walls at that season, when they are subject to the chilling and drenching influences of the heavy dews and rains which so often prevail.

If it can be maintained that from the obstruction of the rays of light by the clearest glass, Peaches on a back wall, or on a trellis a couple of feet from the glass, are inferior to those grown without any such obstruction, what is to be said of those grown as dwarf bushes, set in rows along the floor of a flat-roofed orchard-house? Reasoning from the same premises surely they must be very inferior. Yet we are led to believe that they of the bush are often fine in flavour; that Apples and Plums, &c., are even better than those of foreign growth. If this be so, the flavour in their case must depend upon other circumstances, which cannot be secured without glass, as well as upon light. Till lately I had an idea that Apricots grown under glass were always inferior in flavour to those on the open wall, but under the influence of properly-constructed and ventilated houses I am now convinced that such is not the case; and I know of an employer who this year told his gardener who had sent Apricots to table from a covered wall, that he might say he never knew what a properly-flavoured Apricot was before.

But granting, as I am quite willing to do, that when Peaches can be ripened on the open wall under the influences of a bright and dry autumn, they are a degree or two more highly coloured and flavoured than under glass, I am not at the same time willing to forego the advantages which glass affords in wet and ungenial seasons, which are as much the rule as the exception. Were light the only agent which affected the flavour of fruits and the health of plants, the case would be widely different; but all who have experience in this matter are perfectly well aware that a soil drenched and cooled with rain is inimical to the acquisition of the proper flavour in all fruits, to say nothing of the fruit and foliage being bathed for days and nights with cold dews and rains. To be able to prevent such a state of things must be allowed by the opponents of glass to very nearly, if not quite, make up for the rays of light that are held back. In fact, taking our fickle climate into consideration, there are so many advantages to be enumerated which are secured by protection, that its very slight disadvantages may safely be put up with; and those who contend that all its advantages and none of its disadvantages are secured by simply covering with frigi domo in spring, must surely have a very one-sided view of the climate of the United Kingdom.

In all considerations of this sort the expense is always considered by all concerned; but even in this important point, if the expenses of the respective systems were to be carefully calculated, I feel persuaded that when extended over a period of years there would not be much to show in favour of covering with frigi domo or strong canvass. The erection and heating of glass can now be done so cheaply that it is astonishing how large an amount of such work can be done for moderate sums, and I am labouring under very wrong impressions, if nine out of every ten gardeners would not prefer the glass to any other mode of protection.

D. THOMSON.

GROWING CHRYSANTHEMUMS WITH A SINGLE FLOWER ON EACH STEM.

In replying to the query of "T." respecting the culture of the Chrysanthemums exhibited at the Floral Committee, South Kensington, November 10th, it will be necessary to state that those plants were grown for a special object—viz., that of producing one flower of large dimensions. The method employed was a decided success, but one we should not recommend to be so strictly pursued again, and for this reason: each plant might have been grown to produce three or four large flowers, whereas one only was allowed to be perfected; the consequence was that the plants, not having a sufficient number of buds to nourish, formed unusually stout woody stems. There was nothing uncommon in the treatment beyond the severity of disbudding and thinning out.

To secure fine flowers is easy enough, by taking either cuttings or rooted suckers from an old plant at the latter end of March or beginning of April; these should be potted into 48-sized pots in a mixture of equal parts of mellow loam and well-decayed leaf mould, sufficient silver sand being added to make the compost porous. In a short time the young plants will be well established, and by the end of May should be repotted either singly or in pairs into pots of 10 or 12 inches in diameter, in a mixture of equal parts of loam, well-decayed frame manure, and leaf mould, adding silver sand to keep them porous. Be careful in well draining the pots; crushed oyster-shells will be found very beneficial for this purpose—the roots of the Chrysanthemums seem to rejoice in these fragments.

When potted the plants should be placed in an open and airy part of the garden, and never be allowed to flag from want of water; as the side shoots are produced they should be pinched out, and every sucker that is thrown up from the roots removed. About the middle of July three or four leaders should be encouraged, and from these the flowers are to be produced. Early in August the flower-buds will begin to show themselves, and now some judgment will be required in selecting the bud which is to remain. Generally a single bud presents itself, to which a kind of strap-leaf is attached; this is the bud that produces the finest flower. When that is well defined and has a green and healthy ap-

pearance, at once remove all other buds which are formed above it on the extreme points of the plant; these buds are usually formed in threes. Should the single bud alluded to be unhealthy, then select one of the three terminal buds in its place. The result will be success, however unnatural this process may appear.

The plants should be frequently syringed in the evenings in warm weather. This much encourages the vigour of the foliage. Never use liquid manure till the flower-buds are formed, and as they increase in size so you may increase the strength of the liquid used. That produced from sheep's dung is, perhaps, the best; and should the roots show themselves on the surface of the pot, let them be covered over with rotten manure kept well moistened.

At the end of October, or as soon as the buds begin to expand their petals, remove the plants under cover to protect them from sudden frost or violent rain and wind. If removed to a greenhouse admit a free current of air day and night. It is protection from weather, not heat, that the plants now require. About the first week in November you may expect your reward, your plants having perfected fine, large, and splendid flowers, by no means in the opinion of florists resembling mops with straight handles, so facetiously suggested by a writer in a contemporary respecting the specimens in the conservatory at South Kensington.

VERBENAS.

A SELECTION of the best sorts, as we have found them in this locality (Somerset), may be interesting, especially when taken in connection with "D" of Deal's jury on the same subject (see JOURNAL OF HORTICULTURE, page 387). Having cultivated upwards of a thousand sorts since 1856, and having a great liking for the flower, as I consider it amongst the best ornaments we have for the flower garden, I have taken great pains with it, and am happy to find that the Deal jury have put down a seedling of my own, Miss Hughes, as A.1. I was much pleased with "D," of Deal's "hanging" bout; it is a process that requires to be carried out upon some other families as well as the Verbena.

I bought eighty sorts of the new Verbenas of 1863, but was sadly disappointed with a great many of them, and I think "D," of Deal, and his friends, have served them quite as they deserved; I may say that I never knew a worse lot sent out than those of 1862-3, nine-tenths of them were mere rubbish.

The following list contains what I consider the best of what have appeared during the last ten years. I have arranged them in sections of colour, and made a few observations about each section, hoping that it will enable your readers to choose those sorts only which are most effective and likely to give them the most satisfaction.

SECT. 1, DARK CRIMSON.—Negro Boy and The Moor are two very dark and effective sorts for dark beds, and there is also Lord Elgin, the darkest sort yet produced.

SECT. 2, CRIMSONS.—Admiral Dundas, Chauvieri, Géant des Batailles, Gloire d'Automne, Little Pet, Master Corbet, Rainbow, Rougieri (same as Fanny Stracey). This beautiful section contains colours of dazzling brightness; Chauvieri is yet unmatched in colour, and Rougieri in both colour and form has no equal. The well known Géant des Batailles is one of the best bedders yet out. Master Corbet is new, and very fine for a bed; Little Pet is a dwarf and compact free-flowering gem.

SECT. 3, BRIGHT OR SCARLET CRIMSONS.—Evening Star, La Gloire, Morning Star, Nemesis, Sir J. Paxton, and Star. All these are fine and beautiful flowers with large and conspicuous eyes, excepting Nemesis, which is a lovely and finely formed flower. Mrs. Scott, a new flower coming out next spring, is an improvement upon it, being much brighter in colour, equally well formed, and a very free flowerer.

SECT. 4, SCARLETS.—Comet, Electra, Fireball, Firefly, Foxhunter, King of Scarlets, Lord Raglan, Magnet, Melindres, Mrs. Woodroffe, and Old Defiance. This may be called the most brilliant and most telling section of Verbenas; Firefly, Foxhunter, Magnet, and Melindres are dazzling in their brightness. Melindres is the oldest of all the creeping kinds, and still one of the best for small beds; Firefly is, perhaps, the best scarlet bedder we have; and Lord Raglan,

a different and lighter shade, is unsurpassed for the profusion of its flowers; Foxhunter is a great acquisition; Magnet and King of Scarlets are two lovely sorts, with fine yellow eyes, and are excellent bedders; Mrs. Woodroffe is a large and fine, hardy late-flowering sort. We have a bed here now, Nov. 30th, in fine flower.

SECT. 5, MAGENTA OR SHADED CRIMSON.—Brilliant de Vaise, General Simpson, La Gloire, Miss Hughes, and St. Margaret. These are all splendid flowers. The first is a fine sort for large beds, or for a hanging-basket and vase; General Simpson is a fine and profuse bloomer; Miss Hughes is one of the finest formed and finest trussing Verbenas out, and was a seedling of my own, it is good both for bedding and for pot culture; St. Margaret is one that has stood the test of years, it is a lovely and profuse flowerer, it has kept its place against all comers for nearly thirty years, I think Melindres and this are the oldest of our best bedders.

SECT. 6, ROSE (of various shades).—Mrs. Spencer, L'Avenir de Ballent, Great Eastern, Lizzy, and Great Western. These are all fine, and very free-flowering sorts, and give a pleasing variety to the flower garden.

SECT. 7, BLUSH VIOLET.—Garibaldi, Lady Palmerston, and Mrs. Moore, are all charming kinds, but the first two are rather shy growers; Mrs. Moore is the best of all the blue sorts with white eyes; although not one of the largest, it is a free grower and profuse flowerer.

SECT. 8, PURPLES (of various shades).—Ariosto, Ariosto Improved, Claudia, Desdemona, Eyebright, King of Verbenas, Purple King, and Rival André. These are all fine bedders; the first might be dispensed with, as the second is so much finer. King of Verbenas is a splendid bedder, with a fine eye; and Purple King is so well known, and so good, that it has not yet been equalled in habit or profusion of flowers.

SECT. 9, PURE WHITE.—Boule de Neige, Mrs. Holford, Mrs. Hosier Williams, and Snowflake, are all very fine, the last as yet unequalled, the first has not yet come up to it; Mrs. Holford, when well grown, is a charming variety; and Mrs. Hosier Williams is a dwarf, free-flowering, and upright-growing sort, excellent for small beds, and is of pearly whiteness.

SECT. 10, FRENCH WHITES WITH FINE EYES.—Admiral Lyons, Madonna, and Venus. These are all charming bedders. Madonna is an old sort, but is still one of, if not the best of this tribe; Venus is as she should be, lovely and charming.

SECT. 11, STRIPED FLOWERS.—Carolina Cavagnini, Comte Bernardo Leechi, Madame Zoudier, Madame Lemonier, Noble Carolina Franzieur, Sarha, and Striped Perfection. These are all charming flowers, beautifully striped with a sort of Maltese cross in each floret.

SECT. 12, SMALL STRIPED SORTS OF MACNETTI, purple, scarlet, and white striped, fine for rockwork, vases, and small beds in sunny places.—JOHN SCOTT, Merriott.

HOGG'S BRITISH POMOLOGY.—It will be seen from our advertising columns that this work, of which the first division only has been published, is to be continued in the pages of *The Florist and Pomologist*, of which a new volume will be commenced on the 1st of January next. The subject will be "The Pear," and will contain a full description of every known variety, with woodcut illustrations of all that are most deserving of publication. Such a work as this has been much wanted.

PROTECTING PLANTS.

So much has been said of late about protecting bedding plants from frost, that I think it may not be amiss to inform amateurs of a plan which was recommended a few years back in *THE JOURNAL OF HORTICULTURE*, which plan I adopted, and found it to answer all the purposes required. It is this—

A frame, or frames, made of boards 1 or 1½ inch thick, whatever size suits best (mine are 6 feet by 4); this frame to be cased all round with boards half an inch thick, leaving a space of about 3 or 4 inches, which is to be packed well with dry sawdust. To protect the top a frame is made of half-inch board about 2 inches wide, on which is tacked roofing-felt. This frame-cover is made to fit tightly all round, and to rest on a ledge tacked immediately under the glass

or sash. The plants being thus protected from frost, that hoary-headed general with all his force may storm the gar-
rison without being able to effect an entrance. The only
thing then to be dreaded is the damp in February.

The outer frame should receive one or two coats of gas
tar every year.—S. T. A., *Castlerien*.

THE USE OF FREE OXYGEN IN PLANTS.

DURING the formation of the hydro-carbons by plants,
may not the free oxygen, separated from carbonic acid and
water, be made use of in some other way than that of dissipa-
tion to supply the portion that has been fixed to carbon
and hydrogen in the bodies of animals and other forms of
combustion? Is it not possible that a much larger propor-
tion of the oxygen separated from carbon and hydrogen by
the plant, may have an important office to fulfil in the plant
itself? May it not descend dissolved in the juices of the
plant and exude from the roots, exerting an influence on the
constituents of the soil, combining with its carbon to form
carbonic acid, and its minerals for the osseous structure, and
thus convert substances incapable of being absorbed into a
pabulum suited for the nourishment and structure of plants?
At the same time this radical exudation, if it had this
solvent property, although imperceptibly acid (gastric juice
is also an example of a bland and almost tasteless fluid,
having the property of dissolving and rendering organised
substances, however hard, capable of being absorbed by
the minutest pores of the body), would break down and
convert into a soft pabulum hard, dry substances, ena-
bling the thread-like rootlets to push on and suck up food
more suited for the plant, much after the manner that a fly
feeds on hard sugar, first moistening it and then sucking
it up. This seems rather an interesting question; for, if
true, it would explain how plants grow in climates where
there is no rain, and, consequently, the soil dry, and where
dews alone can furnish moisture for absorption by the
leaves, the roots being useless as far as nutriment is con-
cerned, unless the moisture descend in some such fashion
as I have alluded to. I am aware there is a class of plants
in which the surfaces which are exposed to the air are
covered with a waterproof film to prevent the exudation
of moisture; also, that these grow in countries not watered
by rain. In their case the roots must grow near the surface
to enable the plant to obtain the requisite amount of
moisture. Still plants rooting deeper and not covered with
this film must live entirely upon the moisture absorbed by
their roots. Could the Editors of THE JOURNAL OF HORTICUL-
TURE enlighten me on the subject?—A CONSTANT READER.

[This is a subject far too intricate to be decided by mere
reasoning and analogy. Sometimes plants do not emit so
much oxygen as they ought if they emitted all the oxygen
from the carbonic acid they are known to have absorbed.
But at other times they emit more than the due amount of
oxygen. Experiments have proved that oxygen applied to
the roots of plants invigorates them, but we have no re-
searches on the point here suggested, that plants may supply
the oxygen to their own roots.]

CROCUS IMPERATORIUS.

CAN you or any of your correspondents inform me where
bulbs of the *Crocus Imperatorius* or *Imperati* can be pro-
cured in England, as I have never succeeded in obtaining it
from any nursery garden? I once brought a few bulbs from
hedgebanks in South Italy (Analfi), which I keep in pots
in a cold frame, and they generally flower every year about
Christmas, but have not increased. As January is the
natural time for them to flower, there is no chance of their
ever succeeding in the open border; but as no *Crocus* is
more beautiful it is well worth some care, and the result of
the experience of a successful grower would be valuable to
those who may wish to cultivate the sort (if they can obtain
it), as well as—A CONSTANT READER.

CENTAUREA GYMNOCARPA AND C. ARGENTEA.—I think
your correspondent, Mr. Scott, page 455, makes a mistake
in stating that these two plants are synonymous. At least,

I have the two from the London trade entirely distinct. I
am happy to hear from Mr. Scott, that *argentea* when
planted out is a rival to *ragusina* in beauty. It must then
be good indeed. I have not yet tried *argentea* planted out,
but in pots *ragusina* is the favourite here, but that is no
argument against Mr. Scott's statement of it when planted
out.—D. T.

GARDENING AT CANNES.

I WAS much interested the other day, in looking over
the report of Trentham Gardens in your columns, to see a
number of plants mentioned as doing well in the conserva-
tory there, which I find most useful and ornamental in our
gardens at Cannes. It gave me great satisfaction for this
reason—that I had so often remarked to some of our nume-
rous English visitors that if the Cannes climate were imi-
tated in the English conservatories a similar effect might
be produced in the winter months. To obtain this all
watering must be suspended, and as much air given as pos-
sible, but excluding rain, for six months until about the
end of September, when water might be given freely, and
everything would then push with great vigour and new life,
as is the case here after a burning hot summer. I say water
freely, meaning that a good soaking should be given to the
soil, which should then be left for the winter, as the great
danger in the English climate is dampness, and the object
to be attained is a perfectly dry atmosphere. I am consider-
ing, of course, that everything is planted out in these
conservatories.

I see mentioned as doing well in the Trentham conserva-
tory the *Tacsonia mollissima*: to me it seems a thousand
pities that the *igneia* is not there in its stead, which is far
more handsome and quite as free a grower and bloomer as
mollissima.

The three most remarkable and attractive plants in our
gardens now are *Tacsonia ignea*, the *Chromatella Rose*, and
the *Salvia eriocalyx*. The first is literally covered with open
flowers and buds of a bright scarlet, contrasting admirably
with the thickly-carpeted green wall. The second, queen
of all the Tea and Noisette Roses, is at this moment a per-
fect picture. We have several of them trained in a pyramid
form to the height of 15 feet, and covered with blooms
measuring from 5 to 6 and even 7 inches in diameter, and
as double as a *Camellia*. The third, *Salvia eriocalyx*, is,
without doubt, the best of the whole family, enlivening our
gardens, as it does now, with the great contrast between its
calyx and flowers, the former being of a lovely mauve colour
and thickly studded upon long branchy spikes like balls of
silky wool; and the flowers, of a pure white, peering out from
the centre of each one, give a liveliness to the gardens that
none but eye-witnesses could conceive. This would be well
worth a trial in a conservatory, and I have no doubt would
do well if planted out. Now none of these three is noticed
in the report of Trentham, though possibly they may be
there; but if not I should say, By all means try them, and
I feel sure the result would be satisfactory. The *Abutilons*,
again, such as *venosum*, *giganteum*, *Duc de Malakoff*, and
the white one, which are charming winter-flowering plants,
are now in great beauty. Why not give these a trial? Most
of the other plants we have now in bloom are about
the same as those noticed at Trentham; so striking was
the resemblance that nothing seemed left but this great
difference—that at Trentham they were under glass, and
here in the open air.

I will hurriedly run over the list as I see them in our
garden. *Cestrum aurantiacum*, so highly spoken of by Mr.
Fish, deserves even more than can be said of it, and we have
plants of it 8 feet high and as much through covered with its
golden racemes of flowers; and the *Habrothamnus fascicu-
latus*, a beautiful contrast to the *Cestrum*, although not grow-
ing quite so strong, is now loaded with bloom, and will last
much longer. Nor is the blue one (*Habrothamnus cyanus*),
to be despised, for although a straggling grower, it is very dis-
tinct in all points from any of the others. The rest of the list
consists of *Acacia mriobotryum* (?), invaluable for bouquet-
making; *Capraria lanceolata*, *Cassia tomentosa*, *Eriobotrya
japonica* (Japanese Medlar), *Polygalas*, *Veronicas*, *Lantanas*,
Correas, *Bignonias*, *Salvias* in variety, and *Roses* in profu-
sion; the beautiful *Ipomoea Learii* covering a great length

of wall; and in the immediate neighbourhood of our garden fine plants of *Russelia juncea* covered with its scarlet flowers.

I had long been intending to have a private communication with one of your able writers, Mr. D. Beaton, my old apprentice master at Shrubland, and was in the act of doing so when, to my great sorrow, I heard that he was no more. I feel sure, from the pains which he took in teaching me, that he would have been much interested with my simple description of this beautiful climate. I feel his death is to me as a foundation stone of a house removed. Although, fortunately, I never had occasion to apply to him, I always looked upon him as a sure support to fall back upon if necessary; but my loss is a simple one compared with that of the horticultural world, for which he spared no time or pains.

In conclusion, I cannot omit giving one remarkable instance of the rapidity of vegetation at Cannes. In March, 1862, I sowed seeds of different kinds of *Eucalyptus*, and planted them out less than 3 feet high in May, 1863; they have now attained the height of 16 feet, and are fine, large, graceful trees. I recollect the interesting account in the reports of the last great exhibition given as to the various produce of these trees, and I think that they will soon become timber trees of this country.—JOHN TAYLOR, *Gardener to T. R. Woolfield, Esq., Villa Victoria, Cannes.*

FRUITING STEPHANOTIS FLORIBUNDA.

Your correspondent, Mr. John Edlington, Crom Castle, asks for information on fruiting the above. I will explain how a plant of it was treated when under my care at Ripley Castle. The plant in question was in a border resting on an old brick flue. The soil in which it grew was composed of light loam, peat soil, and sand. The border was 1 foot 6 inches in width, and the same in depth. This was at the back of a succession Pine stove. During the season of rest the soil was kept dust dry. Early in the spring the plant was supplied with plenty of water at the roots and a bottom heat of 78°; and a moist humid atmosphere ranging from 70° to 84° was preserved during the day, and a night temperature of 65°. The same plant produced eight or ten fruit two years in succession.—W. CLARK, *Chesterford Park.*

EXHIBITION OF BEDDING PLANTS.

I WAS very glad to see, by the very interesting communication of your correspondent, Mr. F. W. Adey, in *THE JOURNAL OF HORTICULTURE* of the 1st inst., that this subject is not entirely forgotten.

I think that it was first alluded to by the late lamented Mr. Beaton, and the matter is, I think, well worthy of the consideration of nurserymen, and in fact of all interested in the growing of bedding plants; and this, no doubt, comprises a large portion of the readers of *THE JOURNAL OF HORTICULTURE*.

It must be evident to all in any way conversant with the subject, that but a very imperfect estimation of the adaptability of any variety of plant for bedding purposes can be formed from seeing a specimen or two exhibited growing in pots, and produced under glass.

The question which next presents itself is, How should they be grown and exhibited? I cannot at present turn to the remarks of Mr. Beaton in *THE JOURNAL OF HORTICULTURE*, but I think he recommended them to be grown and shown in boxes. When I read his remarks on the subject I thought the idea was very good, and I cannot now see any objection to it.

It would, of course, be very desirable that a uniformity of size and shape of the boxes or pans in which the plants are grown should be adhered to; so with your permission and with the greatest deference, I would beg to suggest that they be 2 feet 6 inches long, by 1 foot wide, and about 6 or 7 inches deep. This depth, I think, would be quite sufficient. They ought to be filled with plants struck from cuttings in the preceding autumn or spring, and plunged to the rim in the open border, fully exposed to all sorts of weather, not later than the 1st of June. Supposing the exhibition to be held in July, the plants would by that time have sufficiently

developed themselves to cover the entire surface of the boxes or pans, and these might be placed upon the exhibition-table in all respects miniature and portable flower-beds. From having been treated in every way the same as the ordinary occupants of the parterre, the appearance of the plants on the exhibition-table would convey a tolerably correct idea of their merits as bedding plants.

All plants used as bedders might, I think, be grown and shown in this manner, including *Verbenas*, *Petunias*, *Lobelias*, variegated *Geraniums*, &c. Also, the new golden *Tricolor Geraniums*, of which the variety called Mrs. Pollock may be taken as the type. With regard to these an impression appears to prevail that they require something like protection or shelter; but that such is not the case I have no doubt many of your readers have discovered during the last summer, and have found that the more they are exposed to light and air the more intense become the colours of their beautiful foliage, and in most soils they grow as freely as the common Scarlet varieties.

I am rather pleased to think that I am not alone in my endeavours to raise a Ghost in the form of a variegated *Geranium* with *Madame Vancher*, i.e., pure white, flowers. I trust that your correspondent, Mr. Adey, may succeed in doing so; but I have heard that a silver variegated *Geranium* with white flowers does already exist, and is to be seen in the establishment of the Messrs. Lee, at Hammersmith. But my ambition soars still higher than this, and I have not yet despaired of raising a *Geranium* with golden *Tricolor* foliage, and producing pure white flowers. This will continue in one individual plant four distinct colours—viz., green, scarlet, yellow, and white. If I succeed in doing this before your correspondent, Mr. Adey, or any other person, I will with his permission (not without it, as he has already bespoken the name), call it *The Ghost*.—G.

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES.—DECEMBER 8, 1863.

FLORAL COMMITTEE.—This was the last meeting of the present year, and, as might be expected, at this late season there were very few plants for inspection.

Mr. Veitch sent four very interesting varieties of a seedling hybrid *Orchid*, the result of Mr. Dominy's persevering skill. The plants are the produce of a cross between *Calanthe vestita* and *Limatodes rosea*. One seedling, which is named *Calanthe superba*, was particularly beautiful, with a long spike of deep bright rose flowers, the centre marked with a dark spot. This was awarded a first-class certificate. The three other plants were of a lighter shade, and two of them with white centres. These had been before the Committee before, and received certificates.

Messrs. Smith, Dulwich, sent plants of double and single-flowering *Primulas*. The rosy purple double variety, and the double white, were fine flowers, but not superior to others previously exhibited by the same firm. The single variety, a fringed deep rose, appeared to be from the strain of Mr. Benares' *Primulas*. The plants were very young, and not in condition for it to be decided whether this deep colour will remain as the plants advance in growth.

Mr. W. K. Brown, Great Marlow, sent cut specimens of an *Anemone*-flowered *Pomponé Chrysanthemum*, with a deep, full centre of pale lemon; the white back petals were irregular, and too reflexed to make it a perfect flower. It received a second-class certificate.

Mr. Macintosh, Hammersmith, also sent cut flowers of *Chrysanthemum Magenta*. Flower small, colour not new.

Mr. McMorland, Haverstock Hill, sent *Odontoglossum phalanopsis*, an old and well-known *Orchid*, but not very often exhibited. It is one of those which require a cool-house treatment, and like many of its family has suffered much from the high-temperature treatment. The plant though small produced a spike of four or five very beautiful moth-like flowers, white ground, marked on the lower lobes with pale lilac spots and blotches. Not being a new variety a special certificate was awarded to denote its value. When the cool treatment of *Orchids* which will not endure high pressure becomes more generally adopted, we may expect to see again many excellent old varieties, which for a time

have been lost through mistaken treatment in their cultivation.

Mr. Bull, Chelsea, sent plants of a beautiful Saxifraga, japonica tricolor, one of the many interesting plants introduced by Mr. Standish from Japan, specimens of which we saw two years ago at Bagshot. This Saxifraga has most remarkable variegated foliage, the dark green being relieved by bright rose and creamy white variegations. This will prove a valuable plant for suspended baskets. The runners carefully trained would make a very pretty specimen. As a decorative plant adapted for this special purpose, a first-class certificate was awarded to it.

From Mr. Bull also came *Burlingtonia decora* (pieta, Hooker), from Brazil, a well-known Orchid; *Dracena terminalis latifolia pendula*, resembling a species already well known; *Eranthemum rubrovenium*, a variegated-foliaged plant not dissimilar from another variety; *Kennedyia Fredwoodii*, not equal to *K. Maryattae* or *prostrata*. Three plants were placed on the table by Mr. Eyles, from the Society's garden at Chiswick, presented by a gentleman whose name we did not hear—a *Sonchus filifolia* with very thread-like foliage, an *Aralia*, and *Hottonia*. They appeared to be plants unknown, and were too young for any opinion to be formed on their merits.

FRUIT COMMITTEE.—Mr. Nash in the chair. At this meeting there was one of the largest exhibitions of fruit that have been seen during the season. The prizes offered were—Class A. For the best three dishes of dessert Apples, distinct kinds. There were no less than seventeen entries, and all sufficiently meritorious. As is usual in such cases, it was not the largest and the best-looking that proved the best in flavour, and consequently many collections that looked as if they ought to have taken a prize were numbered among the unsuccessful competitors. The first prize was awarded to Mr. Ruffett, gardener to Viscount Palmerston, Brockett Hall, for very deliciously-flavoured fruit of Cox's Orange Pippin, Ribston Pippin, and Cockle Pippin, and all of which were beautiful specimens as well. The second prize was taken by Mr. Simpson, gardener to Lady Molyneux, Stoke Farm, Slough. He exhibited three collections, all of which were very fine specimens of the sorts. That which obtained the prize consisted of Cox's Orange Pippin, Cornish Gilliflower, and Ribston Pippin. The others were Rosemary Russet, Cornish Aromatic, Claygate Pearmain, Golden Harvey, Kedleston Pippin, and Scarlet Russet.

Mr. Cox, gardener to W. Wells, Esq., of Redleaf, exhibited no less than five collections, all of which were different, and consequently contained fifteen varieties of dessert Apples. Among these Sam Young was particularly noticeable as being the finest-flavoured Apple in the whole collection. Cox's Orange Pippin was also very richly flavoured. For this collection the Committee awarded Mr. Cox a certificate of commendation. Mr. Curd, gardener to M. J. Thoytts, Esq., of Sulhampstead, also exhibited a large number of varieties of dessert and kitchen Apples amounting to twenty-five sorts. Many of these were also excellent specimens. In Mr. Whiting's collection the Elford Pippin deserves especial notice. It is a small flat Apple, and seems to be a great favourite with that gentleman, for he has shown it on several occasions lately, and it has been invariably of very fine flavour. This is doubtless one of the best of our dessert Apples. Mr. Beasley, gardener to T. Wood, Esq., Acton, had fine specimens, both in appearance and flavour, of Blenheim Pippin, and also of Wyken Pippin, but his King of the Pippins were inferior. Mr. Earley, of Digswell, who was second at last meeting, had very nice specimens of the true Golden Winter Pearmain. Mr. Dungey, of the Gardens, Oakham Park, Ripley, Surrey, had fine specimens of the Ribston. Mr. Spivey, of Hallingbury Place, sent unusually fine specimens, both in flavour and appearance, of Margil; and Mr. Curd, of Sulhampstead, contributed beautiful examples of the true Cockle Pippin.

Class B was for the best dish of Huyshe's Bergamot Pear, and for this new introduction there were three entries. Mr. Huyshe himself having one; Messrs. Lucombe, Pince, and Co. the other. The specimens of Messrs. Lucombe were, however, the best in every respect, and consequently came in first, while the originator of the variety was himself obliged to take a second place. This remarkably fine Pear is now, with the consent of Mr. Huyshe himself, to be called

henceforth the Prince of Wales. The former name was completely a misnomer, as the fruit possesses neither the shape nor any other feature of a Bergamot. It is, in fact, a long pyramidal Pear.

Class C was for the best dish of Huyshe's Victoria, also a splendid Pear raised by Mr. Huyshe. In this class there were four competitors, Dr. Scott, of Exeter, being first with splendid specimens covered over with fine warm cinnamon-coloured russet, and delicious in flavour; Mr. Huyshe was again second, also with fine specimens, but not so richly flavoured as those of Dr. Scott. Messrs. Lucombe, Pince, and Co., had also excellent specimens, and unfortunately those of Mr. Gray, of Exeter, were rotten at the core.

In Class C, For the best dish of Joséphine de Malines Pear, Mr. Spivey, of Hallingbury Place, near Bishop Stortford, was first with fine fruit, the flavour of which was equal to anything ever met with in that excellent variety. Mr. Cox, of Redleaf, was second, also with well-flavoured fruit, but not so rich in flavour. George F. Wilson, Esq., of Gishurst Cottage, Weybridge Heath, sent very large and handsome specimens from a tree grown in a pot in an orchard-house, but the flavour did not come up to either of the former. The other exhibitors were Dr. Scott, of Exeter; Mr. Samuel Ralphs, Walton-on-Thames; and Mr. Adam, of Walton-on-Thames, but neither of these was at all possessed of any flavour.

A seedling Grape was received from Mr. Meredith of Garston, called Child of Hale. It produces an enormous bunch, with a stout woody stalk and a profusion of large round amber-coloured berries on very short and stout berry-stalks. The skin is thin, and the flesh firm and crackling, of the consistency of the Muscat of Alexandria, but without the flavour. It is very juicy and sweet, with a considerable amount of richness, but unfortunately the skin had a little astringency in it, which has prevented the Committee forming a favourable opinion upon its merits. It is evidently a variety that will hang in good condition to a late period, and when that astringency is absent it will be an invaluable variety, both for size of bunch and berry, for flavour, and for long keeping.

Messrs. Lane, of Berkhamstead, sent bunches of Barbarossa, Black Prince, Charlesworth Tokay, and Golden Hamburgh from an orchard-house. They were all beautifully coloured and well grown, but the flavour was not developed except in the last, which was in beautiful condition.

Mr. Forsyth, gardener to Baron Lionel de Rothschild, Gunnersbury Park, exhibited two splendid Pine Apples, one the Smooth-leaved Cayenne, and the other Carlotta Rothschild.

Mr. Haywood, nurseryman, Worcester, sent stalks of a white Celery, which could not be distinguished from well-grown specimens of the Incomparable. Mr. Melville, of Dalmeny Park, sent a hybrid Turnip between the Swede and the Yellow Stone, which, however, was not regarded as anything superior to what is already in cultivation; also a sprouting form of the Ulm Savoy, which is not equal to the Brussels Sprouts; and a seedling Brussels Sprouts, which is much too large ever to become a thing of any importance, seeing the desideratum in that vegetable is to procure it as small as possible.

SOME GARDENS WORTH SEEING.

The beautiful ruins of Kenilworth Castle are close to the Kenilworth station, and well deserve a visit from the tourist.
—P. M., Fulham.

MISTLETOE.—In your Journal of 24th November, page 419, you ask for any information of Mistletoe growing on other trees than the Apple, Thorn, Poplar, and Lime. There is in the churchyard here a fine large bunch of it growing on the Acacia, and a quantity on a Thorn on the lawn adjoining,

the only specimens I have seen in the southern part of Devonshire. The Apple-orchards are free from it.—*West Ogwell, near Newton Abbot.*

WHAT ANIMALS ARE POISONED BY THE YEW?

"A. J. G." all last summer turned two cows into a small field with a large Yew tree in it, being informed by the man who had charge of them that it was a "bearing Yew tree," and not poisonous. It produces no berries. These cows take delight in eating anything they are not intended to have. So "A. J. G." has little doubt that they ate many small branches of the Yew, and certainly they were none the worse. An old horse spends most of his time in the same field.

How does this agree with the advice given in THE JOURNAL OF HORTICULTURE for the 1st of December, in which a correspondent, "G. B.," is advised to fence off Yews from sheep? On Mickleham downs there are quantities of Yew trees, and "A. J. G." has seen flocks of sheep grazing among them safely. On the other hand, "A. J. G." sent a cart drawn by a donkey to fetch some turf from neighbouring downs. The donkey ate Yew branches and leaves, and died the next day, evidently poisoned.

The country people persist in saying that the Yews which have no berries are not poisonous, and "A. J. G." will be much obliged if the Editors of THE JOURNAL OF HORTICULTURE will say whether this is truth or folly, for "A. J. G." is anxious to let poultry run on a piece of ground where there are several Irish Yews, but is afraid to do so on account of the berries.

"A. J. G." also begs to have two kinds of good late Strawberries recommended for planting under a north wall, and would prefer one kind to be a respectable old-fashioned sort, which can be relied on, being rather out of conceit with novelties at present, in consequence of a failure in growing *Spargula pilifera*.

[You cannot have two better late varieties of the Strawberry than the Elton and Frogmore Late Pine.

With reference to the Yew being poisonous, no fact is more certain than that some animals, and under some circumstances, have died from eating either the berries or the leaves and twigs; and this being so, though similar animals and apparently under similar circumstances, have not been so killed, yet he is unwisely venturous who subjects them to the risk. We will quote a few testimonies. White, of Selborne, states an instance where barrow hogs and young sows were uninjured by eating Yew berries; but sows suckling their young often died after devouring the berries. Gilpin relates instances of horses tied to a Yew hedge being killed; and in the Isle of Ely he had nine of his own young bullocks killed by browsing on a Yew hedge; and knew of a whole dairy of cows killed by eating Yew clippings. Yet, he adds, sheep and turkeys, and, as park-keepers say, deer will crop this tree with impunity. Children eat the berries without inconvenience, and so do fieldfares; yet Withering tells of three children having been killed by a spoonful of the green leaves, and sheep, he adds, have been killed by eating the bark; and many instances are recorded of persons killed by drinking a decoction of the leaves. We shall be glad to receive information upon the subject; but after the above testimony we should avoid turning any agricultural animal into a field where it could partake of any part of the Yew. We should not fear turning poultry into such a field.]

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

DIPTERACANTHUS AFFINIS (Splendid *Dipteracanthus*).—*Nat. ord.*, Acanthaceæ. *Linn.*, *Didymia Angiosperma*. One of the most beautiful of Acanthaceæ plants. Native of Brazil. Introduced by Messrs. Henderson, Wellington Road Nursery. Flowers scarlet, blooming in July.—(*Botanical Magazine*, t. 5414.)

ERIA MYRISTICÆFORMIS (Nutmeg *Eria*).—*Nat. ord.*, Orchidaceæ. *Linn.*, *Gynandria Monandria*. Pretty and fragrant. Native of Moulmein. Introduced by Messrs. Low & Co.,

Clapton Nursery. Flowers white, blooming in September.—(*Ibid.*, t. 5415.)

HELICONIA BREVISPATHA (Short-spathed *Heliconia*).—*Nat. ord.*, Musaceæ. *Linn.*, *Pentandria Monogynia*. Probably a native of South America. Flowers yellow and scarlet, opening in a warm stove during the summer.—(*Ibid.*, t. 5416.)

LIGULARIA HODGSONI (Mr. Hodgson's *Ligularia*).—*Nat. ord.*, Compositæ. *Linn.*, *Syngenesia superflua*. Native of North Japan. Believed to be hardy. Flowers bright yellow, blooming during July in a cool frame.—(*Ibid.*, t. 5417.)

ADENIUM OBESUM (Thick-stemmed *Adenium*).—*Nat. ord.*, Apocynaceæ. *Linn.*, *Pentandria Monogynia*. Native of Aden. Flowers light pink, with dark pink margin. Requires a hot, dry climate.—(*Ibid.*, t. 5418.)

BURLINGTONIA DECORA var. *PICTA* (Painted Neat *Burlingtonia*).—*Nat. ord.*, Orchidaceæ. *Linn.*, *Gynandria Monandria*. Native of Brazil. Flowers white mottled with pink and purple. Blooms in October.—(*Ibid.*, t. 5419.)

FANCY PANSIES, raised by Mr. Dean, of Shipley. *Her Majesty*, two upper petals dark purple, white-edged; three lower petals dark blotched circled by purple, edge straw colour. *Prince of Wales*, three lower petals richly marbled with purple, yellow, and black; two upper petals light purple shaded off to a white edge. *Princess of Wales*, light straw colour, with a pale purple band within each petal, and dark blotch in centre of three lower. *Thomas Moore*, pale straw colour, each petal variously blotched with purple.—(*Floral Magazine*, pl. 173.)

GASTRONEMA SANGUINEUM.—Cape of Good Hope bulb. Flowers scarlet.—(*Ibid.*, pl. 174.)

CLEMATIS REGINÆ.—Cross between *C. azurea* and *C. lanuginosa*. Flowers purplish-blue.—(*Ibid.*, pl. 175.)

PICOTÉE, Colonel Clark, rosy scarlet edged white, very clear, no bar. *CARNATION*, Lord Clifton, a pink and purple bizarre.—(*Ibid.*, pl. 176.)

CLEMATIS FORTUNEI.—Introduced from Japan by Mr. Fortune, and flowered by Mr. Standish, Royal Nursery, Ascot. Flowers white, very large, double and fragrant.—(*Florist and Pomologist*, ii., 169.)

STRAWBERRY, *Frogmore Late Pine*, "raised by that indefatigable hybridiser, Mr. Thomas Ingram, *Her Majesty's* gardener at Frogmore." Fruit large, varying from conical to cockscomb in shape, ripe at same time as the Elton, "but is far superior to it both in flavour and productiveness."—(*Ibid.*, 172.)

BERKHAMPSTEAD NURSERY.

Some time ago we gave an account of this nursery, so deservedly celebrated for Roses, its collection of fruit trees, weeping or pendulous trees, standard evergreens—as Portugal Laurels, Rhododendrons, &c.; fine specimens of *Araucarias* and *Deodars*; its economical span-roofed houses, and economical heating by hot water, hot air, Polmaise stoves, &c. Our object in paying a visit in the end of September was to see a house of Grapes, most of which were then ripe. A good report of these had been brought to us, and we felt a particular interest in them, as we had the good fortune to see the Vines during the process of planting. Having frequently advocated drainage and a suitably made border for Vines, and having lately described how these processes are attended to in two of the best Grape gardens in the country, we think it is only fair that the readers of the Journal should know of a very successful case of Grape-growing where no attention whatever had been given to draining, and all the border-making was the simplest imaginable. The house is span-roofed, 126 feet in length and 27 feet in width, height to ridge about 11 feet, and at sides about 3 feet. The sides of the house face the south-west and the north-east. The ground on which it stands slopes to the east to a brook near the canal, and it is built on the slope. At the highest end of the house, as at c, fig. 1, there is an open spring well, the

Fig. 1.

A. level.

C.  B. Slope.

water standing not more than 2½ feet from the surface, and

therefore higher than the surface of the lower part of the ground on which the house stands—just such a position as one would suppose that stagnant water would have to be guarded against.

When first we saw the house the sides were supported by stout larch poles, and a row of poles went along the middle to sustain the ridge-board. As far as we recollect, the house was either not a true span or the north-east side had the ground lower; and there the opening from the glass to the ground was filled, we think, with a hedge of Arbor Vite. The object of the house seemed chiefly to be to give the protection of dryness and of a still atmosphere to great numbers of things in winter. The south-west side was partly open and partly protected by such temporary means as bushes, mats, and in a few cases by louver boards, the roof being fixed in the regular orchard-house fashion.

In order to make the house a large storehouse for fruit trees in pots and many other things that required a little protection in winter, when Vines were planted on the south-west side they were placed from 4½ to 5 feet apart, that the usefulness of the floor of the house all the year through might not be impaired by the Vines.

Unfortunately we cannot lay hold of our memoranda as to the year—not very long ago—when these Vines were planted, and we forgot to ask Mr. Lane; but so far as we recollect, in forming a border for them there was not a spadeful of the natural soil touched or removed. We have already indicated that the ground on which the house stands slopes considerably eastward; and just in front of the south-west side it slopes a little towards the south-west, but not much. In planting the Vines for this open wall-less house all the preparations made were putting a good barrowload of fern above the natural soil, and then placing a few barrowloads of fresh loam from the common on the fern, and on this soil disentangling and spreading out the roots of the Vines. As the Vines grew, fresh soil with a similar bottoming was added; but even now the made border does not extend more than 5 feet in width, and presents the appearance indicated on the south side of *fig. 2*. The roots have no doubt extended much farther; and we should have supposed that they had pushed into the inside of the house as well as outside but for the following circumstance.

Fig. 2.

The very cold winters of 1860 and 1861 showed the necessity of having a more secure shelter at the sides, and, therefore, the deeper north-east side was walled up to the plate on which the glass roof rested. The south-west side was filled up, partly by a wall and then with glass on the top of it. The foreman and Mr. Lane told us that they had found no roots inside of that wall, though the mounds of decomposing tan, sawdust, and litter inside would have been an inducement for the roots to revel in, if they had obtained the chance to do so. The very intelligent superintendent, who may well be pleased with the heavy crop of fine Grapes, is anxious that the wall should be cut into arches, or pillars, that the Vine-roots may be encouraged inward, making for them at first a small narrow border, and increasing the width as the roots occupy it; and then he would cut a drain some 12 or more feet from the wall outside, and put up a wall there below ground to prevent the roots going farther. He is afraid that unless something of this kind is done, and if similar heavy crops are taken, that the Grapes will be apt to shank or colour badly when a wet unfavourable summer comes. As the Vines are flourishing so well, we feel persuaded that Mr. Lane will adopt at least a part of these suggestions, merely as a preventive of what might prove an unpleasant contingency.

These suggestions, however, apply to the future, and not to the present condition of the Vines, which have as yet received no coddling, except watering the narrow border several times during the summer with drainings from the dunghill, and covering it in September with short sashes of glass, so that the heated air might enter freely and yet the rains of autumn be thrown off. During the past summer for the first time, we think in July, two hot-water pipes have been taken round the house, which for the future will so far take away its purely orchard-house character. The help of these pipes in future will also assist in the thorough ripening of the fruit, the preserving it when ripe, the hardening of the wood, and the preserving still more securely the vast number of plants in pots stowed away here in winter.

We mention these little matters as likely to be interesting; but let it be recollected, that until July the Vines had no help except what was given in an open orchard-house, and from a small border of 5 feet in width made on the surface of the natural soil. The sight of these Vines in September was a very striking one, most of them being in full bearing, and they reached from the south-west side up to the ridge and down to the bottom of the north-east side. All were heavily, and many rather too heavily cropped, which in a few instances might impair their full colouring. The bunches in general were large, and the berries of full size. We measured some berries of Black Hamburgh somewhat at random, and found that they ranged from 3½ inches and more. We counted the bunches on a number of Vines, and they numbered from thirty to forty on each Vine. On one fine Black Hamburgh Vine we counted them particularly and found forty-three bunches, and some of these were very large. We are sure that these forty-three bunches would average 2 lbs. each. Notwithstanding such a heavy crop the Vines seemed in full health and vigour, showing that the roots were not idle somewhere. As one evidence of their vigour, we may mention that some shoots laid into pots at the far end of the Vines on the north side were making splendid canes of wood, receiving a little additional help from the pot.

The kinds thus planted outside and grown across the house from side to side were Black Hamburgh, Mill Hill Hamburgh, Dutch Hamburgh, Pope's Hamburgh, Golden Hamburgh, exhibiting a little tenderness in the foliage, showing that a slight shade in summer would be useful;

Muscat Hamburgh, the bunches large, thick set, and the berries squeezed against each other, having grown too large for the thinning given them, and which will be apt to interfere with their colouring fully up to the mark. In some places this Grape has set very badly this season. We think the low temperature may be an advantage. We should judge some of these perfect balls of bunches to be little under 4 lbs. in weight. Esperione was not colouring so well as others; Black Prince, West's St. Peter's, Frankenthal, Buckland Sweetwater, and Barbarossa, had fine large bunches, but berries much smaller than other varieties, and looking as if they would need the hot-water pipes to ripen them. It will be noticed that, with the exception of the Barbarossa, most of the others would come in about the same time—a matter often of importance in a commercial point of view; but it is different in a gentleman's garden, where succession of supply is of greater moment.

So many inquiries are made whether anything can be grown under the shade of Vines, that we must mention what we found on the floor of this house. Of course it would be differently filled in winter. There is no attempt at nicety in the internal arrangements. The most of the plants in pots were plunged in mounds of sawdust, but so moved (as on inspection we found), that the roots should protrude little or nothing. Here we observed some excellent Figs in pots, chiefly the Grand Florentine, a beautiful large Fig; the White Marseilles, the prolific variety, than which none is richer; the well-known and prized Brown Turkey; and the small, sweet, White Singleton, a good old Fig under a new name, but having the fault that it seldom yields a good first crop however treated—at least we have found it so oftener than was agreeable. With good pinching, however, the second crop comes early, and generally sticks on as if fastened mechanically.

The most striking objects, however, on the floor of the

house and in these mounds of sawdust, were Vines in pots, mostly in what are called No. 8-pots, the Vines being trained round three or four stakes; and though many of the earliest kinds had been partly cut, the Vines averaged from five to eight bunches to each. We counted eight fair-sized bunches on several Black Hamburgs; noticed some very good Buckland Sweetwater; also some fully ripe bunches of the Early Malingre, a very early medium-sized White Grape, well worthy of being more generally grown; West's St. Peter's, about eight good bunches; Royal Muscadine, nearly all cleared, but showing that there had been a good crop; White Frontignan, nice bunches and good berries; and Prolific Sweetwater, which seems to set freely and thickly. Charlesworth Tokay, Trebbiano, Muscat Trovère (new to us), and Bowood Muscat, set well. Canon Hall Muscat, Tokay, and White Nice were not ripe, showing that they would need more heat and time. We noticed also fine berries of Kempsey Alicante, Lady Downes', Trentham Black, and Bidwill's Seedling, resembling, but seemingly earlier than Black Prince. We also observed near this very fine specimens of Comte de Lamy Pear, also the Vicar of Winkfield Pear, and fine plants in pots of Angelina Burdett Plum; but Mr. Lane exhibits fruit trees in pots so often that we need not further allude to them here.

In other houses we noticed great numbers of beautiful Fig plants in pots with good Figs on them, so that there could be no mistake about the sorts; and several houses, such as the large Polmaise-heated Rose-house, were filled with thousands of Vines—some treated for fruiting next year, and others standing as thickly as the pots would stand, with wood reaching to the roof and beyond, wood and roots being the chief objects aimed at for mere planting out.

Go where you will—to Berkhamstead, to Sawbridgeworth, to Cheshunt, to Messrs. Veitch, Lee, Glendinning, Osborn, &c., and take a peep through the metropolitan, the suburban, and the country nurseries—and young Vines not in thousands but millions will meet your gaze. "Where do they all go to?" is what we feel inclined to exclaim until we see the vast number of little glass houses rising by the side of even small dwellings, and all wanting their few Vines, not only for the pleasure of eating the fruit, but enjoying the many legendary and poetic associations connected with it. We know of nothing that tells more of the progress our country is making in wealth and refinement than the sight of these innumerable Vines, in connection with the fact, that in many of our nurseries the sale is so immense that the proprietors have to look sharply after buds for propagating. If we live long enough we shall see the day when in the suburbs of large towns and in the streets of country towns such houses as will be tenanted by tradesmen and well-conducted mechanics, will each of them have their little greenhouse between or attached, so that in quiet meditative moments their inhabitants may literally "sit under their Vine and under their Fig tree." With continued peace and the increase of temperance and prudence, there is nothing to prevent the hardest workers in our mines, foundries, factories, and workshops having homes resembling little paradises.

Passing over all the varied contents of the nursery with merely noticing that the Rhododendrons flourish in the natural loam of the grounds at the common, and that among the large quarters of fine Araucarias there are two or three so compact and beautiful as to be worthy of being photographed and engraved, we shall proceed, in answer to many inquiries, to say a few words on the Polmaise and brick-stove heating, and the modes of propagation adopted in some houses built since our last visit.

The large Polmaise-house is heated as effectually as it used to be, and without adopting the principle thoroughly, it is partly carried out in most of the arrangements for heating. Thus we formerly described a long house 100 feet in length, built on the steep incline of the ground, as in

Fig. 3.

fig. 3, A. This house has a peculiar roof as if made of odds and ends, as shown in fig. 4. c and d are two beds with a

rather deep pathway between them, the beds and the path being on the same slope as the ground. The brick stove is placed at the lower end, B, fig. 3, and a pipe is taken from it for a short distance along and then out at the back wall, as shown in fig. 4. Everything seems to thrive well in this

Fig. 4.

house, and this single brick stove keeps it warm enough for what is wanted. Here there is no regular carrying out of Polmaise, and yet its principle is brought happily into action. The very singular construction of the roof also helps it, as it divides the currents of heated air as they pass along near the glass to the further end, nearly 100 feet, and then the air, falling down as it cools, is brought by the heat of the stove along the path to be heated again and sent along its former course. This circulation will to a certain extent take place in any house however heated, but there can be no question, that the slope of the ground, and consequent slope of roof, the slope of the deep pathway, and the placing of the brick stove at the lowest point, all unite in making the circulation more uniform and equal. As the stove stands free of all walls but its own, the heat from the fuel is freely radiated from all sides. No other plan that we know of could approach this in economy, and the consumption of fuel we can well believe to be very trifling.

Close to this house the chief novelties were some glass-roofed lean-to sheds, which in addition to providing comfort when working in bad weather, would be found convenient for storing many plants in winter; and there were also several beautiful beds of the most popular shrubs arranged according to their foliage in lines in ribbon fashion, and also some quarters of Yew grafted, 5 feet in height, with the Silver and Golden varieties.

The largest propagating-house is not more simple than complete and effectual. See fig. 5. It is 60 feet in length and 20 feet in breadth, and divided lengthwise into three beds by two pathways a little more than 2 feet wide. The house is span-roofed and 10 feet in height to the ridge. The beds are separated from each other by brick walls, 3 feet in height, at the sides of the pathways. The side beds are 4 feet wide. Each of these is heated by two four-inch pipes in a chamber beneath. That chamber is covered over with slate resting on iron cross-bars. Sand is mostly laid on the slate for placing or plunging the propagating-pots in. These are covered over by moveable short sashes, represented by the upper line. The wall that separates the bed from the pathway has openings in it alike for heating the atmosphere of the house and securing the circulation of the air. The smaller openings F, at fig. 6, let in the cold air from the path, and are placed some 2 feet apart. The larger openings, G, are furnished with slides, and are placed some 4 or

Fig. 5.

more feet apart, so that by them the bottom heat and the atmospheric heat may be regulated at will. The dry or moist heat given to the cuttings can be regulated to a nicety by the dry or moist condition of the sand. The centre bed

h, fig. 5, is from 6 to 7 feet in width, and heated by four pipes beneath, with openings also for air cold and hot as desired. This bed is chiefly covered on each side by small bottomless wooden boxes, the wood being about 6 inches deep and glazed on the top. These boxes stand close together, and air can be easily given by tilting at one end and side, and just as the cuttings will stand it. The boxes may be removed for a time and then altogether until the young plants are taken elsewhere. No place could be better for fresh-potted plants for a time, for store plants in general, or anything requiring heat. On part of this centre bed a high glass case is placed for plants requiring extra heat, and for grafting and inarching those plants of considerable size, which could not otherwise be so well managed. On our visit in September this house was filled chiefly with myriads of the newer Cypresses, Thujaopsis, Arbor Vita, and the scarcer of the Pine tribe, many rooting and others calling for rooting. At another time the house would be found filled with Rose cuttings. The superintendent seemed to think nothing of turning out of this house forty thousand Rose plants at a time, and said the beauty of such a house was, that it was fitted for almost numberless purposes.

Now, many of our readers who wish a nice propagating place could not think of any such house as Mr. Lane's; but still they may receive a hint how they can construct one on a small scale. The numerous inquiries on this subject may render a few ideas not superfluous. Now, suppose any one wishes to have a small lean-to house 8 feet high at back, 4 in front, and 10 feet wide, he might have a similar pit in front covered with moveable glass frames; part of that pit may be used for fresh cuttings, part for potted-off plants, and the part behind either as a bed or stage for plants

Fig. 6.

GROUND LINE

We will finish with presenting one more example of a most useful combination of house and pits as seen in fig. 7. The house is 13 feet wide, 8 feet in height to the ridge. The pathway is some 2½ feet in width, with beds on each side heated as described in fig. 5 when necessary to do so. On each side of this house are pits now filled with hundreds of Azaleas, Camellias, &c., Magnolia exoniensis, and many other things, a side letting out the heat from the chamber in the house whenever the severe weather would render it necessary. The pits or beds in the central house were filled with small plants in pots of Hollies, grafted in August with the variegated kinds; and now the glass sashes that covered them were elevated to the sashes of the house, that the Hollies, already taken and all right, might be hardened-off

hardening-off. To make such a plan effectual would need three pipes in the chamber if all the heating were to proceed from that—namely, two flows and one return. If more heat were wanted or cuttings were required to be struck in the first months of the year, there might be two pipes in the chamber and two on the open bed for top heat, to act independently of each other; and if the latter were the case the chamber might be filled below the pipes with clay and above them with bricks, clinkers, a surface of clean gravel, and then sand, &c. But even hot water is not necessary; for a length of 20 to 30 feet a good stout flue once through the chamber, with slides, &c., as shown in fig. 6, would answer the same purpose. Where economy is the great object, for lengths not less than 20 feet—and for all such contrivances as small pits and frames from 12 to 20 feet in length—a chamber, with slides, heated by a brick Arnott stove below and a small chimney from it, would be amply sufficient if properly worked and attended to. We would place that stove so as to be fed from the outside, with an old door to stand in front of it to moderate draught and keep the heat in the chamber. For unpractised hands we would recommend the stove with a short flue; but to men of intelligence and experience, we are fully convinced that a small house for propagating and hardening-off plants may be effectually managed with a brick stove alone, and as recently stated, there are no modes so economic as this for heating small places. Mind, however, that for places of large size the hot-water plan is the best. For small places we are convinced that nothing is better or more economical than brick stoves. See the Kiddian system of heating as illustrated and propounded some time ago by our lamented friend Mr. Beaton.

Fig. 7.

and then planted out of doors. Well might the superintendent say, "What cannot be done in such a little house with its outside pits?" And well might he add it will never do in a commercial establishment to have a house that you can only use for one purpose. There is not a single practical man but sees to what purposes he could use such a house if he was fortunate enough to obtain it. We will express no opinion farther than this—that we have never visited Mr. Lane's establishment without feeling more and more that there is no reason why the most thorough economy should not be combined with the greatest efficiency, and, leaving the extreme of elegance out of the question, that combination is what seven-tenths of our readers most require.

R. FISH.

WORK FOR THE WEEK.

KITCHEN GARDEN.

IN this department continue to trench, manure, and, where necessary, to drain the ground, preparatory to its being cropped in spring; and where the crop is to be a comparatively permanent one, as Asparagus, Rhubarb, Globe Artichokes, or Sea-kale, a thorough preparation will be necessary, as the best guarantee of future profit and satisfaction. Asparagus, if the heat of the first bed should decline much before it has done bearing, it will be necessary to add a lining. In making successional-beds use a quantity of leaves with the dung, which will keep up a more moderate degree of heat, and retain it for a greater length of time than all dung. Broccoli, as they will be advanced by the recent mild weather, look over and select the most forward for protection before the return of frosty weather. Continue to

remove all dead and decaying leaves. Brussels Sprouts, in gathering do not cut out the crown until the spring. Some do so in the hope of inducing them to throw out more sprouts than with it, but this is generally injurious at this season, as it admits moisture, which, in the event of severe frost, proves fatal to the whole stem. Cauliflowers, stir the surface of the soil amongst the plants under hand-lights, and sprinkle some lime dust amongst them; it will sweeten the surface of the soil, prevent a green growth on the surface, which stagnant air is apt to produce, and will also prevent the depredations of slugs. Celery, take advantage of every favourable opportunity till frost occurs of earthing-up the late crops, both for the purpose of blanching and protection. Herbs in pots should be introduced to the

forcing-house. *Lettuce*, those in frames for present use to be kept dry and free from dead leaves. *Mushrooms*, the beds to be cleared from wet litter about every week, and a covering of dry hay put next to the bed, over which must be laid sufficient straw or other covering to preserve the beds from frost. *Peas*, sprinkle wood ashes or lime over the early crops as they appear above ground, the weather that causes their appearance excites insects to activity. Set traps regularly for mice. *Spinach*, when gathering do it with care. It is improper to lay hold of the whole plant and strip off a handful, for this not only removes the leaves that are mature and fit to gather, but bruises and tears those which are young and immature, and prevents their further progress. Each leaf ought to be removed separately. These are small matters, and for the same reason they are the more likely to be overlooked and to require pointing out. See that all goes on well in the root-house. *Turnips*, on the first appearance of severe frost it is advisable to take some under cover. They may be laid in sand after the tops are cut off.

FLOWER GARDEN.

Dig or trench all vacant pieces of ground, leaving the surface as rough as possible. Sweep and roll grass lawns and gravel-walks. Afford protection to tender plants by a liberal supply of suitable materials. Prepare composts, soils, and manures, by frequent turnings. Examine *Dahlia* roots to see that they are not rotting; for the want of this attention many persons are disappointed at finding them in the spring only fit for the rubbish-heap. Every advantage of the present favourable weather should be taken for transplanting trees, shrubs, &c. See that the principal and choice plants in the shrubbery have sufficient scope to develop their true and natural characters. There are few situations in the pleasure ground more interesting than a well-regulated and well-arranged shrubbery, where every tree and shrub from the largest to the smallest has room sufficient to form perfect specimens. Collecting shrubbery plants appears to be much less attended to than their merits deserve.

FRUIT GARDEN.

Apple trees newly planted should be malched. Trees planted against walls, or as espaliers, to be pruned. Cut off that part of the spur which bore fruit last summer, down to the fruit-buds formed on the lower part of the stem of the spur; take out all bruised and cankered branches, and leave a regular supply of wood throughout the whole. Those in orchards will merely require the branches to be so thinned that they cannot injure each other by rubbing one upon the other. Fig trees on the open walls will require protection with mats, and the ground about their roots should have some litter laid upon it. Gooseberry and Currant trees may now be pruned. Cut away all shoots from Gooseberry trees, except one or two springing as near as can be obtained from the origin of each main branch. Shorten the young shoot left at the top of each branch to about ten or twelve buds, and leave, throughout the tree, the fruit-bearing branches about 6 inches apart. In pruning the Currant, keep a good supply of young shoots springing from the bottom of the tree, and cut out more or less of the old every year, never allowing a branch to remain more than four or five years, and head-in the young shoots at the top to about two eyes of the main branch from whence they spring. Only a few straggling branches of the Black Currant will require topping to keep it in proper shape. Peach and Nectarine trees trained against the walls should have the nails and shreds drawn from the small branches, leaving only so many as will prevent the branches breaking or rubbing against each other in windy weather.

GREENHOUSE AND CONSERVATORY.

The advantage of observing and maintaining strictly the niceties of order and judicious arrangement in the distribution of plants, is not only repaid by the gratification rendered to the eye, but will be manifested by the improved health of the plants. As the practice is not unfrequent, the recommendation that a very limited amount of artificial assistance in temperature is required by the occupants of the greenhouse may not be inappropriate. In houses unfavourably situated in damp or shady situations, fires must be brought more frequently into requisition, not so much to increase the temperature as to allow of a con-

stant and active circulation of air to counteract the injurious effects of damp. Give the *Chrysanthemums* a good supply of water and air in fine weather. In general, at this time, greenhouse plants must receive very little water, and as much air as the weather will permit, and only fire sufficient to keep out the frost and preserve the house perfectly dry. *Camellias* may be introduced into a warm situation to bring them into flower, but if the heat in which they are placed far exceeds 50° Fahr., the flower-buds are liable to fall off without expanding.

PITS AND FRAMES.

Auriculas and Polyanthus must be well secured from frost, and have plenty of air in fine weather. Mignonette and Intermediate Stocks must be exposed to the open air as much as the weather will allow, but they must be well secured from severe frosts.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

SWEET and raked leaves, and trenched some ground when fine; the trenching, being intended for Carrots, &c., was done between three and four spits deep, so as to bring up a little of the lower subsoil. The last spit was left in ridges, and this, when turned over again, we will top-dress with a little lime or burnt clay. From constant dressing with tree leaves, as we have little else, the surface ground has become too rich for Carrots and such like straight-rooted plants, and this season and last we had a number of them forked instead of forming one straight root: hence the deep trenching; and the rich soil being placed at the bottom, there will be an inducement for the roots to go down. Instead of the deep trenching, to save such labour we made holes with a dibber, and filled with light sandy soil to encourage the roots to go down straight and unjointed; but we have not found that so effectual as deep trenching, and having the richest soil at the bottom and the poorest at the top. The greatest wonder, however, that we have ever seen in Carrot-growing was produced by a good dressing of bog earth and lime, and this seemed to suit strong land and light land alike, especially when used on old garden ground. For ourselves we have long felt that without such means as deep trenching fine Carrots are difficult to grow in old kitchen gardens; and even when fine roots are obtained, we do not think they have the rich flavour of those grown on fresh land for the first time in a well-stirred field. We would say the same as to Turnips. Of course they are very nice and early from a garden, but they seem to us, especially late in the season, to be destitute of the flavour of those grown in an open field, and especially if Turnips are not often taken from the same ground.

Packed-up Celery-beds with a little stubble, which will keep frost out and let air in. The beds were well strewn with burnt earth and rubbish previously, which slugs and worms dislike only a little less than quicklime. Took up another piece of Asparagus, and put in a frame over a slight hotbed. But for getting the ground changed nothing is so expensive as this early Asparagus. Put in, also, a little more Sea-kale and Rhubarb in the Mushroom-house, and covered the Sea-kale out of doors with burnt rubbish. The first Sea-kale in the Mushroom-house is now in good condition for use. Earthed-up a small piece more of a shallow Mushroom-bed. What we at first did from necessity we should be inclined to do now from choice, where a constant regular supply is wanted—namely, make small bits of beds, and plenty of them, one after the other. Unless for a month or two in summer, when the beds bear longer under the thatched shed, we have always a little bit of a bed in hand. For instance: we have one piece bearing that has produced heavily; a second piece that has produced a few large ones, and is just whitening with dots all over; a third piece earthed down about four weeks ago; a fourth spawned eight days ago, and now earthed up; a fifth ready to spawn; and a sixth that is now preparing, and giving out a little heat for the benefit of the house. In all these there has been a good proportion of dry turfy soil mixed with the litter and horse-droppings, and when these are well beaten early in shallow beds the virtue of the manure is not lost by overheating. We disapprove in general of making holes in beds to cool

them, as it is a great waste of the virtues of the manure, and dries it too much. We prefer heating hard, which, by excluding air, soon checks the heating arising from rapid decomposition. If the manure is too wet, then adding a little cut straw and throwing it in a heap would even be better than riddling the bed with holes, though in such a wet state the making holes or boring all over is more permissible. Were we spawning such a damp bed we would wrap each piece of spawn in a good handful of dry short litter, but preferring straw and rejecting hay litter as more liable to damp. We have used clean straw for such a purpose, but we prefer that which is broken, such as may be collected near a manger, or in a shed where horses or cattle congregate for food and shelter.

FRUIT GARDEN.

Having raised the roof in Fig-house as well as plant-stove, made a rough trellis about 18 inches from the glass to give what support may be necessary, and keep the shoots out of the way. Hitherto the plants have been trained chiefly in bush fashion; but even then a little support was necessary to keep the fruit in the best position. Protected Strawberries from one frosty morning. All not protected have the pots laid on their sides, and can be protected by litter in a few minutes. Sprinkled Vine-shoots in small narrow pits, and kept the evaporating-pans filled with manure water. We should not care how rank this might be for Vines, but the pits are filled with plants, and, therefore, we have the water more mild than there would otherwise be occasion for before the buds broke. For general purposes we know of nothing better for this manure water, when used for evaporation, than strong clear soot water. This may be made by mixing a bushel of soot and a spadeful of quicklime in 36 gallons of water, or even 52 gallons, with a cover to the barrel. The scum taken off such water will be bright as the finest old ale, and will throw off a good portion of nitrogenous matter without hurting, as far as we have found, the tenderest plants. We have made a paste with the soot in the evaporating-pans and then filled with water, but this clogs the evaporating-receptacles in time, and when convenient we prefer the previous mixing. No insects like the fumes from such water, and we have found that few or no plants dislike it. Went on pruning and nailing as the weather would permit. Now is still a good time for all kinds of planting, as the ground is still warm. Cuttings of Gooseberries, Currants, &c., should be made in wet days, but should not remain long unplanted. Other matters much the same as in previous weeks. With all our care the leaves must be removed from the late viney, the Grapes in which are still keeping very nicely.

ORNAMENTAL DEPARTMENT.

We have begun regulating some of the herbaceous plants, and digging and trenching-up the beds and borders for bedding plants. Being scarce of well-rotted manure of any sort, our practice for several years has been to dig, or rather trench, pretty deeply, but leaving the bottom spit at the bottom, and keeping fully three-parts of the surface at the surface still, in order to reap the advantage of the little manure that was placed near the top. This deep stirring we believed saved us from scorched beds last summer, when for two months we had not enough of water for pot plants, and everything outside had to take its chance. Many an afternoon the Calceolarias especially looked woe-begone, but they mostly were all right again the following morning. We had satisfied ourselves that this deep stirring was just as effectual in preventing extra luxuriance in damp and wet seasons. This season, in order to bring a little fresh soil to the surface, we will stir as deeply, but will bring up more of the under soil to the top, will let it be exposed all the winter, will turn it once or twice, leaving it as rough as possible, and in early spring will cover the surface with some leaf mould, and keep that in turning not far from the surface to encourage active growth at first. All such changing of the surface should be done gradually. We recollect of a large piece of a waste being trenched for planting trees, and after several failures this ground had pretty well to be trenched back again before anything would grow, so that the expense of such trenching was worse than labour lost. Had the ground been deep ploughed, or if even fair-sized holes had been made, or the surface spit well broken, and the bottom then well picked up and left, there would have been

no doubt that trees and anything else would have done well. A case came under our notice not long ago of deep trenching, where some 8 inches of hungry clay and irony marl were brought to the surface, to the discomfort of everything and everybody. If well stirred at the bottom and an inch or two brought to the surface, it would have been sufficient.

As soon as we can we will plant a border with bits of Cerastium, variegated Arabis, &c., for edgings, as it is as well to have rooted plants to go to, and they will root nicely before April. The hardier Roses may now be pruned; the more tender Perpetuals, Teas, &c., had better be unpruned until the end of March or the middle of April. A little leaf mould put over the roots of the latter, and evergreen boughs stuck over the bed, will much protect them against cold. Such branches or fern may be tied round the heads of standards budded on the Dog Rose, &c.; but for nice plants of Teas and other tender kinds, and dwarfs in a bed, no plan is better than taking them up carefully and planting them in a bed in a shed, or against a fence, and thatching them up, taking them out and planting in the beginning of April. When used to it, they will hardly seem to notice the moving more than its securing for them moderate growth and well-ripened wood. Bulbs may now be potted for succession crops. Those coming into bloom in the forcing-pit or frame should have more air, and the pots should be gradually raised out of the hotbed, that the plants may receive no check when taken to the greenhouse, conservatory, or window. In such mild damp weather it is desirable to put a fire on in the greenhouse during the day now and then, and to give extra air, letting the fire out before night. As little fire should be used at night as possible, even when there is a little frost. Camellias in full bloom will require a good amount of water. Heaths and Epacris will need abundance of air, and the soil must not get dry. The pots should be rung frequently with the knuckles to ascertain the state of dryness, and when nearly dry, enough of water at about 50° should be given to wet all the soil where there are roots. Early Calceolarias and Cinerarias will be less likely to be troubled with fly, if the pots stand on cool, damp moss. Primulas will need plenty of air to keep them from damping, and a little manure water will do them good; but it should be kept from the collar of the plant. The water should chiefly be poured round the outsides, but so as to moisten the whole ball instead of drenching the collar of the plant. Now is a good time for placing hardy shrubs, as Deutzias, Lilacs, and Rhododendrons into forcing-pits or houses, and also Roses. It is best to begin gradually. In fact, for all these hardy things it is no bad plan to plunge the pots in a mild hotbed out of doors first. Damp must be looked after in all pits and frames, and we have plants in general kept cooler and drier than at other seasons. Of course, exceptions must be made as to plants in bloom and coming into bloom.—R. F.

HOMEY HINTS FOR MARRIED GARDENERS.—If you fail in raising the wind abroad, that is no reason why you should kick up a breeze at home. No soil favours the cultivation of spare time as well as the domestic hearth. Beware of hiding the family bread-basket in the public-house till. Keep your Passion-Flowers outside the walls of your homestead. If cultivated within doors, they are apt to scatter seeds of dissension around the family table.

COVENT GARDEN MARKET.—Dec. 12.

The supply continues unusually heavy owing to the mildness of the season, but prices continue much the same. In Apples and Pears there are no fresh varieties to add to those named in previous reports, and remarkably fine samples from abroad continue to be exhibited. Of Potatoes, heavy supplies are brought both by rail and coastwise, and Flukes appear to be the freest from disease. Kidney Beans have just made their appearance. Cut flowers chiefly consist of Roses, Pelargoniums, a few Orchids, Epacris, Violets, Wallflowers, and Christmas Rose.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 162, Fleet Street, London, E.C.*

DESTROYING WORMS IN SPERGULA PILIFERA (T. A.).—Put two stones of lime in a hogshead, and pour seventy gallons of water upon it. Stir it well up, and let it stand forty-eight hours. Water the Spergula with the clear liquid by means of a rose watering-pot. Give a good soaking in watering beds in summer, and it will kill many and bring a great number to the surface, which must be swept with a brush or broom. It is best applied in showery weather, as the worms are then nearer the surface; and the operation will be greatly assisted by rolling the Spergula plot with a heavy roller the night before applying the lime water. It may be necessary to repeat the application at intervals of once a fortnight for a short time. Ammoniacal liquor is a more effectual remedy; but it should be highly diluted with water, and even then it turns grass brown, and would no doubt do the same with Spergula pilifera.

GREENHOUSE PLANTS FOR SHOWING IN AUGUST (T. A.).—Yours is a very difficult question to answer, for though most plants have a certain set time as it were, yet their flowering depends in a great measure on the treatment given. Some need retarding, others forcing, to have them in bloom at a certain time. We give the names of eight, so that you may choose:—*Clorodendron Bungei*, *Crowea saligna*, *Erythrina crista-galli*, *Indigofera decora*, *Phenocoma prolifera* Barnesii, *Pteroma elegans*, *Statice brassicifolia*, *Tremandra ericoides*.

KEENS ON STRAWBERRY CULTURE (C. S.).—Mr. Michael Keens was a nurseryman at Isleworth. He never published a work on Strawberry culture; but two communications from him on the subject were published in the "Transactions" of the Horticultural Society.

CELERY DISEASED (G. B.).—The leaves you enclosed were severely infested by the Celery fly. Pick off the worst parts and burn them. Soot sprinkled on the leaves whilst wet will prevent its attacks; but when once it gets hold of the plants there is no cure but burning the leaves.

PORTABLE STOVE IN A GREENHOUSE (M. S.).—We are sorry to say you could not have obtained a worse stove for your purpose than that which you have purchased. There is no combustible article that does not emit smells that vitiate the atmosphere; and, worst of all, we see nothing like a chimney in the engraving which you enclosed. We advise you to discard it, and have a flue, if you possibly could have such without setting the wood on fire. The air would not only be made too dry; but the escape of hydrogen and carbonic acid would be enough to kill everything in your greenhouse. If a small boiler and pipes are not too great an expense we would recommend that as the most effectual means of heating your greenhouse. If you were to have a pipe connected to your "hand stove," and that pipe communicating with the open air, so as to act as a chimney, you might then prevent a great deal of the danger to be apprehended from dryness by having an iron pan made to fit the top of the stove, which could be kept full of water. The water in the pan would be evaporated as fast as the stove heated the atmosphere. A flue, however, is better than a stove of any kind, and a boiler better than all.

GUANO WATER AS MANURE (Idem).—Two ounces of guano dissolved in a gallon of water may be applied to any description of crop with advantage. Two gallons at a time would be sufficient for an ordinary-sized Gooseberry bush, but it should be applied in the evening. A watering of this kind once a-week would, we should think, enable you to grow Gooseberries better than most persons. Four ounces of guano sprinkled on the surface around your trees and slightly raked in would be washed down to the roots by rains. An application of this kind when the buds begin to swell, and another when the fruit is set and about the size of peas, would give them all they need, and do quite as well as watering the trees weekly. The waterings should be discontinued after the fruit changes for ripening.

HARDINESS OF COLEUS VENSCHAEFFELTII (Idem).—It requires a rather warm greenhouse to keep it in good condition through the winter; but an ordinary greenhouse will preserve it sufficiently for affording a supply of cuttings in the spring. Keep dry at the root, moisture being the cause of the shoots dying back. We should think it will sprout again in the spring, only keep it dry, giving no more water than just sufficient to maintain vitality.

APPLES (Idem).—Allston is a good kitchen Apple, in use from November to April. If you wish for one coming into use earlier, Gravenstein is a useful baking Apple. For dessert, Red Astrachan, in use in August and September; Court of Wick, October to March; and Cox's Orange Pippin, November to February, are first-class eating Apples.

CELERY DISEASED (Bessie).—The Celery leaf shows marks of the punctures of the fly; but greater part of the brownness is occasioned by the leaves having been frozen. Sprinkle soot over the leaves, picking off the worst parts and burning them. After that earth the Celery well up, and spread some litter, fern, or stubble, &c., over the leaves in severe weather.

RASPBERRIES (T. E. M.).—Both the varieties you name are good. We never grew them together, therefore cannot decide which is best.

BOTANY (Nemo).—For a beginner the best work is Henfrey's "Rudiments of Botany."

MEALY BUG ON BIRCH TREES (F. W. S.).—You should have sent us, in a small card box by post, a piece of the affected bark. However, if you thoroughly paint the trunks of the trees, to the height affected, with the following mixture, it will probably remove the evil; but repeat it next year if any of the pest recurs. Mix 1 lb. flowers of sulphur, 1 lb. Scotch snuff, 1 lb. quicklime in powder $\frac{1}{2}$ lb. lamp black, 1 lb. soft soap into a liquid the consistency of paint by adding water to it.

TRAINING PEACH TREES TO A TRELLIS NEAR A SOUTH WALL (W. W.).—We fear that unless your situation is one of the most favoured ones in the kingdom, that you will not succeed well with Peaches trained on a trellis a foot or so from the wall. The trees at that distance will derive but little advantage from the wall, and we would advise you to plant the best kind of Pear, and perhaps one or two Plums instead of the Peaches you mention; or what would be better, could you not make terms with the owner of the wall to allow you to stretch your wires against the face of it? Very little harm would be done it by the few fastenings wanted, and your Peach trees would succeed better than if at a distance, for, as you will see by many reports in our columns, Peaches do not in all cases do well against open walls, so that many have resorted to the plan of covering the walls with glass. To attempt to train trees at a distance from a wall without any additional protection, can hardly succeed excepting under the most favourable circumstances, and even then only in certain seasons.

LEVELLING AND RELAYING TURF ON A LAWN (M. D.).—If your soil is rich it is most likely you will be annoyed with wormcasts in mild autumns, and these will be the more conspicuous if you keep mowing very short. As you are now relaying your turf we would advise about an inch of coal ashes under the turf as a partial remedy for this evil. Sand is not so good, but we have known old tanners' bark used under turf. Generally speaking, however, good ground produces the turf most free from daisies; but we are not certain but plantains grow more abundantly, and worms are more prevalent. Most sandy soils produce moss, which if not in too great abundance is an acquisition in the opinion of most people, although others object to it. If you reside in a moist neighbourhood you may use sand and indifferent soil with impunity under your turf; but if you suffer from summer droughts, and it be important to give your lawn a nice appearance, then let the understratum be good—if you have the means of making it so. Generally speaking, when alterations on the lawn are going forward, the best soil is reserved for beds or shrubbery borders, and we have often enough been obliged to make shift with very indifferent turf, and lay it too on ground anything but inviting; but it worked itself right in a year or so.

YEW HEDGES ON A CLAYEY SOIL (W. B.).—We do not think mulching as you speak of will be of any benefit, as this is merely used to retain moisture to newly planted trees in dry seasons, whereas your place you say is rather damp. The best plan, therefore, would be to take up the plants, if they are not too large, and excavate the site, say 18 inches deep and about 4 feet broad, and fill it in with a lighter soil containing a good proportion of stone, at the same time thoroughly draining the ground on all sides of the Yew hedge. If the coming spring and early summer be dry, mulching then may be of service, but if moist it will not be wanted. The clay you take out of the trench may be turned to good account by being burnt in the manner frequently described, and any additional clay may be treated the same way. The charred substance so obtained will be of great service in imparting increased fertility to the stiff ground remaining, which may also be rendered somewhat better by the application of lime.

LATE PEARS SPOTTED AND DECAYING (J. B. B.).—The evil you complain of is by no means uncommon, and we do not think a wash, as you suggest, with Gishurst compound in the preceding winter will have the desired effect of preventing the decay. On the contrary, we expect the cause lies in the roots of the trees; and as you say the climate is a moist one, we would advise the trees to be taken up and planted on the surface, adding a large quantity of stones or other similar substances to the mixture they are grown in. Some varieties of Pears suffer more than others from the disease complained of, and it would be worth while trying more kinds than those mentioned. At the same time it must be borne in mind that the evil in most, if not all, cases arises from the roots, and to remedy that by laying the roots more dry will be one of the most likely means to effect a cure; and if the trees are not luxuriant we should manure the surface of the soil in early spring, and keep it mulched throughout the summer.

ELM TREES BECOMING VARIEGATED (N. A. B.).—There have been many speculations as to the cause of variegation in plants. Some attribute it to disease, others to the absorption of water in a state of decomposition, and others to light and electricity. We do not profess to say if any, or which, of these is the cause; but there can be no doubt that variegation is induced by a peculiar condition of the plant's structure, which is acted upon by light, and produces various shades of colour in the leaves, which is termed variegation. In some plants the colour is red, others have white or gold variegation, but not all are acted upon in the same way by light. For instance, Crotons lose their variegation when shaded, whilst Caladiums require shade. Variegation evidently decreases the vigour of any plant, and variegated plants are more tender than those which are not so; but we do not consequently attribute variegation to disease, for variegated plants have as healthy constitutions as green-leaved plants. Variegated plants, in some cases, have a tendency to return to the original condition, but the fact remains that some plants never exhibit that tendency. Some variegated plants refuse to seed, others increase readily that way. The year 1860 was very productive of variegation, and that was a year of unusual wetness and cold, so that plants grew badly and failed to ripen the growths made. We have varied colours among cattle, and as these colours are dependant on the parents, it seems to us that variegation is a natural process, and we cannot tell the reason; nor why some fowls have leathers of one colour, whilst others have various colours, and that upon the same feather. Hares become white in some countries in winter, and when the skin of an animal is destroyed the hairs upon the same place invariably come white. Disease appears to us to be the opposite of variegation.

AUBRIETIA PURPUREA AS AN EDGING (*A Lady Subscriber*).—The Aubrietia may be planted now, or early in spring. It will look well in the spring of the year, but be only green afterwards; and therefore we do not think it equal to the Cerastium well kept, if brightness is an object. As a green edging it is very good; but as an edging it is not so showy as the variegated Arabis. In a shady place the Moss Saxifrage makes a beautiful edging. For the season through we would prefer the Cerastium, but that is no reason why you should do so. We like everybody to choose for themselves in these matters, and then we have the pleasures of variety. The Cerastium does best when fresh planted every year.

CULTURE OF FERNS (*A. W. Hills*).—Of the Ferns mentioned, Pteris tricolor, Asplenium viviparum, Gymnogramma L'Hermieri, are stove Ferns and should occupy the warmest part of the house; and of plants Stephanotis floribunda, Hoya carnea and H. bella require stove heat. These with the three stove Ferns we should advise you to discard, and keep your house for greenhouse plants only. You cannot grow stove and greenhouse plants together successfully. Of the others you name all will do well in ordinary greenhouse heat, at this season 40° at night and 45° by day, with air on all favourable occasions with sun, or in mild weather. The British Ferns should be placed in the coolest part of the house, and be kept rather more moist than the other plants. The warmest part of your house will be where the flue enters the house, and the coldest the farthest from the furnace. The plants will need no syringing at this season, and only water at the root to prevent the leaves flagging, which may be once or twice a-week, but do not water them before they are dry, then give enough to run through the pot. In addition to the plants you possess, Camellias, Azaleas, Cytisus racemosus superbus, Boronia Drummondii, Chorozema cordata splendens, Acacia hybrida, A. armata, Cyclamen of the Persia species, Daphne odora, Monochætum ensiferum, Fimælea Hendersoni, Polygala Dalmaniana, and Statice brassicifolia might advantageously be added, but that depends on the size of your house. Above all things avoid crowding. Of creepers, Kennedy monophylla, G. liacina, Mandevilla saxeolens, Ipomæa ficifolia, Hibbertia grossulariifolia, and Jasminum gracile, one up each raster only. Oxalis Bowiei requires abundance of light and air, and then it flowers freely. We fear you are keeping the house too warm for its occupants except the stove plants, which we again advise you to exchange for greenhouse plants or discard. The Begonias should now be kept dry at the root, and the Selaginellas should be placed with the Ferns in part of the house to themselves, keep moister than the other part. Aristolochia siphoclamatis lanuginosa, Lonicera fragrantissima, Passiflora corollæ, white Jasmine, and Wistaria siccoides are handsome creepers for a south wall.

EARLY VINES FOR A STOVE—VINES, PEACHES, AND PINES TOGETHER (*Nottingham*).—Taking all points into consideration, there are no two better early Grapes than the Black Hamburg as a Black, and Buckland Sweetwater as a White variety. We cannot advise you to make the attempt to grow Pines, Vines, and Peaches in the same house. Vines and Pines are successfully grown in the same house when the house is so constructed as to let the Vines be taken out for the winter to rest. Vines and Peaches are also grown together very well by having the Peaches on the back wall and a Vine up each raster of the roof, so far apart as to let a fair share of light reach the Peach trees; but unless you can turn both Vines and Peaches out to rest you cannot grow Pines also in the same house; and even if you could do this, the Peaches do not like the heat necessary for Pines. We would advise you to put the Peaches and Vines together, and not attempt the growth of Pines in the same house. The Vines being your chief consideration, they can rest along with the Peaches, and need not be turned out of the house at all. You will find this arrangement satisfactory, but not the one you propose. There are few things that militate so much against good gardening as the attempts that are made to grow so many plants requiring different management in the same house.

FILLING-UP BLANKS IN A VINEY (*A Beginner*).—If your sole object is simply to fill up some blank places in the roof of your vineery where there are (as we presume, from what you say) already established Vines, your best and quickest way is to run up the required number of young growths from the bottom of the established Vines. This is a very simple matter. It only requires that you select a strong healthy-looking young growth from the lower part of your Vines when they burst into growth next season and train it up the blank place, not stopping it until it gets within 3 feet of the top of the house. The number of these young growths that you must allow must depend on the closeness on the blanks you are desirous to fill up, bearing in mind that 2½ feet is close enough for the main rods. If, on the other hand, your object be to introduce any different varieties as well as to make up your blanks, your best way will be to inarch the varieties on to the young green stock and scion to make 2 or 3 feet of growth, and then to unite them about the middle of the young growths, which is a very simple and certain operation, and forms a quicker and better union than that of old wood to old. Young green wood will unite with old perfectly well too, but we much prefer both the stock and inarch to be of the season's growth. All that is needed is to take a slice from the sides of each and fit the two nicely together, and tie them together with soft matting. In three weeks the union will be effected. The planting of young Vines, as your note regarding the roots of established Vines is a practice we do not like; but if you adopt that method of making up your blanks, then the best thing you can do is to introduce as much fresh turfy soil with about a fourth part rotten manure as you can without disturbing the roots of the old Vines, and to plant your young Vines in this fresh soil. The Vines should be strong well-ripened canes of last year's growth, with 6 feet or so of wood nearly as thick as your little finger. When you plant them, shake them entirely out of the soil in which they have been grown, and unravel all the roots, and lay them out carefully in the fresh soil, very much in the same position as you and rest your weight on the palm of your hand in the soil where the roots are to be laid. Cover them over to the depth of 8 or 9 inches. The end of Vines will fill up your space with wood that will bear to the top of the house, or nearly so, which is more than you can expect by planting young Vines under such circumstances. If looks on the Vine were to meet all special cases that arise they would be ponderous volumes.

PEARS FOR A NORTH-EAST AND EAST WALL (*J. W. D. S.*).—You will find this selections of Pears at the end of the descriptive list in the "Fruit Manual." You do not say where you live, nor the soil and situation where they are to be planted. What suits one place will not do in another.

BONE MANURE FOR POTTED VINES (*G. H., a Constant Reader*).—We would recommend you to use bone dust or half-inch boiled bones in preference to unboiled bones. Boiled bones are not richer than those that are not boiled, but they are more rapid in their manurial action, and, therefore, though less lasting in their effects, are best for potted Vines, in as far as more nourishment will be available from them in a couple of years; but the preference is given to unboiled bones for lasting effects in a Vine-border, for the fat makes the decomposition of the gelatine, and the solubility of the phosphate of lime less rapid. An eight-inch pot full of bones, one barrowload of calcareous—that is, rather tenacious—loam, and half a barrowload of rotten horse-dung, make a first-rate compost for potted Vines. Firm potting for the last shift is advisable for more reasons than one. With such materials and 18-inch pots you should be able, all other things being equal, to grow very strong Vines. They should be grown in a light place trained near the glass, and if a little bottom heat can be given them all the better. These conditions with a temperature fully higher than for Grape-forcing, should enable you to give your neighbour a run for the championship, and keep him from laughing at you.—D. T.

TREES, &c., FOR A SMOKY SITUATION (*A Lady Gardener*).—The following trees, shrubs, and Roses do moderately well in and around our large towns, and would, no doubt, suit you:—Acer campestre, A. pseudo-platanus, ditto foliis variegatis; Esculus hippocastanum; Fagus sylvatica, ditto asplenifolia, cristata, fol. argenteis variegatis, pendula, and purpurea; Fraxinus excelsior aurea, ditto var. pendula, F. excelsior pendula, and F. juglandifolia; Liriodendron tulipiferum; Platanus acerifolia, occidentalis, ditto pyramidalis, and P. orientalis; Populus alba and P. acerifolia; Quercus nigra and Q. rubra; Robinia hispida; Salix americana pendula, S. caprea pendula; Tilia alba and T. alba pendula, T. europæa, ditto lacinata, and parvifolia aurea; Ulmus americana, campestris, fulva, macrophylla, montana, pendula, and utriculifolia crispa; Allanthus glandulosa; Hawthorn, all the species; Sambucus heterophylla, S. nigra fol. argenteis, S. nigra fol. aureis, S. nigra lacinata, and S. nigra purpurea; Sorbus aria, S. aucuparia, S. aucuparia pendula, and S. aucuparia pendula variegata; Salix adiantifolia; Betula nigra, populifolia, B. populifolia lacinata, and pendula, and B. utriculifolia. The above are mostly trees. Of shrubs Andromeda floribunda; Aralia japonica; Aucuba japonica, A. japonica latimaculata; Azaleas, most varieties; Berberis arctica, Bealii, Darwini, and vulgaris; Buxus species; Cerasus caroliniana, vulgaris asplenifolia, C. vulgaris flore pleno, and the double French variety; Cornus mascula variegata; Cydonia japonica; Cytisus alpinus, laburnum, nigricans, and secundus; Daphne cneorum, collina, and mezereum var. Deutzia gracilis and D. scabra; Erica, australis, mediterranea, stricta, cinerea, var. alba, coccinea, and pallidus vagans, vagans alba and rubra, and vulgaris alba, Alporti, Harmondii, tetella; Forsythia viridissima; Kalmia angustifolia, glauca, and latifolia; Ligustrum japonicum and vulgare; Preonia montana, varieties; Philadelphus coronarius and P. coronarius flore pleno; Pyrus punifolia rosea, and spectabilis; Prunus triloba; Rhododendrons, the Laurels of towns; Ribes aureum, Gordonianum, sanguineum, var. spiræa callosa, Douglasii, sorbifolia, and arifolia; Syringa Emodi, plicata, rothomagensis, vulgaris, vulgaris alba and vulgaris Philæmos; Vaccinium buxifolium and frondosum; Viburnum opulus, roseum, plicatum, and lucidum; Vinca major, var. fol. variegatis, reticulata, V. minor fol. argenteis variegatis, and minor fol. aureis variegatis; Ilex aquifolium, ditto foliis variegatis, var. Roska.—*Provenç*: Cabbage. *Moss*: Common, Rouge du Luxembourg. *French*: Boule de Nanteuil, Kean, Ohl, Transon Gombault, Pierre Jausseus, Napoleon. *Hybrid China*: Blairii, Brennus, Chénédol, Général Jacqueminot, and Madame Plantier. *Hybrid Bourbon*: Charles Lawson, Coupe d'Hébé, Paul Perras, Paul Ricut, President Mole, and Charles Duval. *Climbing Roses*.—Alice Grey, Ayrshire. *Bourneaults*: Amadis and Gracilis; The Garland, Madame d'Arbay, of Hybrids; and Félicité Perpétuelle, Adelside d'Orléans, Rampant, Princesse Marie, and Princesse Louise are the best of the climbers. *Hybrid Perpetuals*: Beauty of Waltham, Baronne Prevost, Caroline de Sansal, Colonel de Rougemont, Cornet, Anna Alexieff, Comte de Nanteuil, Duchesse of Norfolk, Duchess of Sutherland, Général Jacqueminot, Géant des Batailles, General Washington, Léon des Combats, Marquis of Ailsa, Madame Vidot, Lord Raglan, Madame Dumage, Prince Léon, Scoteur Vaisse, Souvenir de la Reine d'Angleterre, William Jesse, and Souvenir de Leveson Gower. *Of Tea-scented*: Melanie Oger, Sombrenil, Souvenir d'un Ami, and Gloire de Dijon. Brennus, we think, would most likely suit you to plant by the house; Vivid is also suitable for such a situation. Why not water the Peach tree, and syringe it on the evenings of hot days, and thus obviate the dryness of the situation? We think most of the trees and shrubs would do moderately well with you; but you must not expect them to do as well near a town as they do in the country. Laurels do not thrive in smoke, and the Laurustinus will not suit your exposed situation.

TWELVE GOOD HARDY RHODODENDRONS (*Donegal Subscriber*).—The following are good hardy, not high-priced, late-flowering sorts; but we would advise you to tell what you want and the money you wish to spend to the tradesman, and he will do better for you than abiding by any list of names. Say that the plants averaged from 3s. 6d. to 5s. or more, if you wish them rare and fine:—Abd-el-Kader, Alaric, Brayanum, Cannaleto, Duc de Brabant, Erectum, Maculatum, Marshallii, Ne Plus Ultra, Sir Isaac Newton, The Grand Arab, Vandyke. These are all good hybrids. You could obtain a dozen very good varieties of the hardy Catawbiense section for less money; but we advise you to leave a good deal to the nurseryman.

APFELANDRA LEOPOLDI CULTURE (*J. F. Dawson*).—We experience no difficulty in growing this plant. It requires perfect drainage and a moist atmosphere, without wetting the leaves much by syringing them, in addition to all the light practicable. Dribbling waterings are to be avoided, as they cause the leaves of this and many other plants to turn yellow and fall prematurely. The soil should consist of light loam from rotted turf half, and fibry sandy peat (not bog soil) the rest, with a free admixture of silver sand. A moderate stove temperature suits it. We do not see why your plants should not do well. Something must be radically wrong with the roots. Are the pots well drained, and is the soil about them sweet?

CAMELLIA BUDS FALLING (*Idem*).—We think either that the Camellia roots got too much soaked in the border in which they were plunged, or that the ball got too dry; either cause would produce the effect. We do not know the *Lastrea* sufficiently to say.

VARIOUS (C. D.).—The manual you mention is not in print, and Hogg's "Fruit Manual" is far superior. You can have it free by post from our office for 3s. 10d. Spirit of turpentine thoroughly brushed into the places where the American blight appears will destroy it. The insects go down to the roots in winter. For what purpose do you wish to "wash"—we suppose you mean to paint—your fruit-tree walls?

PAINTING CONSERVATORY (W. W.).—It will not injure the plants.
 NAMES OF PLANTS (M. H. R.).—The Fern is *Asplenium labellifolium*, and the others are—2, *Tortula muralis*; 3, *Evernia prunastri*; 4, *Parmelia parietaria*; 5, *Ramalina fraxinea*; 6, *Parmelia saxatilis*. (J. L. C.).—1, appears to be top of frond of *Asplenium Belangeri*; 2, *Adiantum pubescens*; 3, *Celsia subulnata*. (*Ignoramus*).—1, *Erica hyemalis*; 2, *Erica persolota*; 3, *Erica pubescens*; 4, *Epacris impressa*. (*A Constant Subscriber*).—*Hypnum fluitans*. (J. B. H.).—1, *Abutilon venosum*; 2, One of the *Alonsoas*, but too much perished to say which—probably *urticifolia*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BUYER AND SELLER.

HAVING observed lately in your Journal many complaints and disappointments recorded by purchasers of poultry from private individuals, such purchases in no way answering their expectations, I think I can propound a scheme of the simplest character by which the interests of both purchasers and sellers would be entirely secured—that is, every one parting from their valuable birds may be sure of either receiving them back, or their money value when sent on approval, and need have no uneasy visions of the "Long Firm" while the negotiation is pending.

As an old poultry and pigeon fancier, I have been compelled at different times to purchase birds without seeing them, a plan I would recommend no one to adopt, and I cannot say that I have had reason to be satisfied with that mode. In more than one instance I have not received anything at all for money sent in prepayment, and I certainly think in most cases the purchasers may be considered quite as honest as the sellers—this is said in reference to the now general practice of demanding prepayment.

I do not think with the "WILTSHIRE RECTOR" that the public generally distrust advertisements, witness the daily supplement to the *Times*; nor do I think that any good could come from "a column set apart, &c., &c." (at a reduced price of course), vigilantly excluding all dealers, as suggested by the "EXHIBITOR (and no doubt dealer) IN A SMALL WAY." Who, indeed, shall decide who is a dealer when every one deals more or less if he can? Why, what are the people who would fill that half-priced column but persons anxious to buy or dispose of their surplus stock? No, what the public require is some guarantee or security, where prepayment is required, that they will not be deceived by misrepresentations, and that they may be sure of receiving a fair value for their outlay.

This could be very easily carried out by establishing in London, as most central, a "poultry protective agent," to act for both buyer and seller, and to whom all payments, as a sort of stakeholder, could be made. Then, when a buyer required a lot of birds to be sent on approval, he would forward to the agent the amount of their value; the agent would then acknowledge the receipt of the money, and request the owner to forward the birds direct to the purchaser (this would save trouble to the agent). If the birds were approved the purchaser would inform the agent, who would pay over the money to the seller, making such deductions for carriage, &c., as might be previously agreed on. If the birds were not approved of the same form would be gone through, only that the birds would be sent back to the owner, and, after their safe arrival, the agent would return the money to the proposed buyer, deducting such fees as might be agreed on. This would terminate the transaction, and no one would have to complain that he had been deceived in the quality or defrauded of his property.

It may appear on paper a troublesome process, but in reality could be carried out very easily; and I think when the amount is considerable, few would object to take this trouble, any more than they do to the "formality of an advertisement" to obtain anything of choice quality.

I think if the subject were fairly gone into, others might offer their opinions on this much-vexed question, and some arrangement speedily come to. The only person I know of in London, who would be suitable for such an agency, is Mr. Stevens, the poultry auctioneer, who probably would be willing to undertake it if suitably remunerated for the trouble, &c. This would not entail more than writing two or three notes with postage, and which a fee of 3s. with 5 per cent. on the purchase money, whether sold or not, would cover.—ONCE BIT TWICE SHY.

[Another correspondent, "A. N. B.," makes a similar suggestion, but proposes that the Editors of this Journal shall be the protective agents. It would involve more writing and occupation of time than the Editors could sacrifice.]

CAPTAIN HEATON'S COCHIN-CHINA FOWLS AT THE BIRMINGHAM SHOW.

ALLOW me to correct an error made by your correspondent, "SMALL FRY." He asks:—"How the astounding fact arose that Captain Heaton, to whom both the Silver Buff Cochins were awarded on the Saturday, and his friend, Mr. Kelleway, the breeder of the greater portion of the Cochins fowls the Captain then exhibited, were permitted to view the Poultry Show on the Saturday, in flagrant violation of such arrangements?" Your correspondent would evidently deprive me of a great part of the honour of my victory. I beg to state, for his especial benefit, that out of the fifty Cochins exhibited by me at Birmingham, only thirteen were from Mr. Kelleway's yard, the remainder from my own. As to his charge against the Birmingham Committee, I will leave the matter in better hands than mine; I can only say, that I am not aware that any favour was granted to me or Mr. Kelleway, we merely followed many others who entered the poultry department before we did.—HENRY HEATON.

RAILWAY ARRANGEMENTS AND POULTRY EXHIBITIONS.

AMONGST the many suggestions lately made by "EGOMET" and others as to poultry shows and poultry, the following, *inter alia*, will not be out of place:—I think one of the largest items connected with the expenses of exhibiting is carriage of poultry to and from shows. Some Secretaries have, with commendable foresight, obtained from the respective railway companies connected with their exhibition a free transit for the poultry to and fro, and, I think, they have added by doing so a great attraction to their prize schedules—in fact, at once lessening distance between north and south, east and west, and giving opportunities to those who otherwise could not show. I feel sure that did Secretaries of shows secure this privilege, even of returning poultry from exhibitions free, they would find the number of entries increased; and through the medium of your Journal I beg to offer this suggestion to them, which I hope will be received, approved, and acted upon.—MEIRSUM.

DARLINGTON EXHIBITION OF POULTRY.

WE can with the most perfect confidence assure our readers, that the Darlington Show just closed has not only very far exceeded all others hitherto held under the auspices of this Society, but also proved itself quite able to hold equal rank with the most noted of our poultry meetings elsewhere. The earnest determination of the managers "to do everything they possibly can for the benefit of each exhibitor, but to show no partiality to any of them above their fellows," has doubtlessly contributed very materially to produce the amount of public confidence now so freely given to this great Exhibition. Scarcely a county exists that did not this season send admirable specimens of poultry to Darlington. First-prize birds from all our most noted shows stood here side by side. Such pens having previously secured their local honours, the owners, now wishing to determine their actual perfections, brought them together as antagonists, in many instances for the first time; a whole host of silver cups of the actual value represented being the coveted objects of their ambition. From these especial causes not only were the classes heavy as to the numbers exhibited, but almost without exception of so perfect a character, that the Judges had a duty to fulfil the very opposite of a sinecure. This year the poultry were exhibited in the recently erected Market Hall, at Darlington, which proved itself a most suitable building, and consequently far in advance of the temporary erections that hitherto have been the only ones available to the Darlington Committee. Mr. Turner, of Sheffield, provided the Society with his well-known exhibition pens, so that a better oppor-

tunity of displaying to advantage every pen could scarcely be wished for. "A fair field and no favour" being thus made the order of the day, we proceed to note down a few of the leading features of this Exhibition. Black Spanish fowls were the first variety that met the eye of visitors on entering. To sum up facts with brevity, both the classes, whether for old birds or chickens, were beyond question the most praiseworthy that ever yet have been seen at any poultry exhibition. They were indeed marvellous classes, and long, very long, we hear, were the Judges in arriving at their conclusions of relative perfection. In no case was this more apparent than in the awarding of the silver cup to the best pen irrespective altogether of age. Certainly a sad length of time was absolutely wasted in this selection. In vain did the Judges endeavour to pick faults either way, the adults and chicks of 1863 being so perfect that complaint of either was undoubtedly to find fault without occasion. The condition also of either pen was unexceptionable. It was most probably the severest "tie" that ever occurred at any poultry meeting; and, as was justly observed, "to give the cup to either in preference was an absolute injustice to the defeated; but as the cup could not be divided, a selection however undesirable must be made." Simply on account of the difficulty of finding chickens able to hold their own in perfect Spanish classes against old birds, the result was finally determined in their favour. Our readers may form their own opinions of the annoyance to the Judges at this vexatious delay, when it was afterwards ascertained both of those closely matched pens actually belonged to the same exhibitor—the Right Hon. Viscountess Holmesdale. Of course the Committee are quite exonerated from all blame; their duty was scrupulously to prevent any knowledge of facts as to proprietorship coming either directly or indirectly to the Judges, and honestly and to the letter did they carry out this duty. No doubt they regretted the evident downright "fix" of the Judges as much as the gentlemen who were officiating.

To say not a single pen of *Spanish* fowls was shown without great merit is simply stating a most indisputable fact; nor is it less true that those lovers of Spanish fowls who unfortunately missed seeing these classes this year at Darlington will most probably live long before such an opportunity again occurs. Referring to the prize list, amateurs will find scarcely a pen of Spanish fowls exhibited unnoticed. The Grey *Dorkings* were excellent throughout, but many of the best pens were evidently overtaxed by frequent exhibition. Mrs. Fergusson Blair here took the cup with a grand pen well shown of adult birds. The chicken *Dorkings* were especially good throughout. The Show at Darlington gave incontestible proof of the injury done to birds by frequent exhibition, even as applied to that extraordinarily hardy race of fowls, the *Cochins*. If they are to be always on travel they must always have attention lavished on them in proportion. In *Buff* Mr. Bates, of Birmingham, "justly ruled the roast" with birds of not only very superior character, but also in perfect condition; Mr. C. T. Bishop, of Nottingham, being a very close-treading second prize, the Birmingham cup pen only attaining a commendation. In *Buff* chickens Mr. C. T. Bishop took precedence of all comers, Captain Heaton being the winner of the second prize. In *Cochin-China* fowls, any variety, there was a capital muster. Here, somewhat unexpectedly, a pen of remarkably good White ones, exhibited by Mrs. Blair, took not only first prize, but the cup for *Cochins* also. In this class Mr. Stretch showed a particularly good pen of Partridge-coloured ones, which took the second premium. Captain Heaton's first-prize pen of a pair of *Cochin* pullets are worthy of especial mention, as also his excellent single cock that was equally successful. In the class for *Single Cochin Cocks* it has never fallen to our lot to notice so evidently wrong statements as to age as was then apparent; but perchance this was from some mistake in packing. In these days it will hardly pass muster to show as chickens certainly birds of full two and perchance three years old. The *Brahmas* were good throughout. The *Game* classes were of such regular, capital, first-rate character as we only rarely meet with, and this condition was no mean feature in securing the Darlington premiums. Messrs. Fletcher, Adams, Billing, Sunderland, Perkins, and Binns sent poultry in these classes that were hard as whalebone in feather, and

evidently fresh from master-walks. Mr. Fletcher, of Manchester, added considerably to his plate-winnings at Darlington; and each winner of even a commendation in such competition has much to be proud of. So good were a pen of Black-breasted Red Game pullets, that they took a silver cup against their male rivals. *Hamburghs* were decidedly better than customary, this district being proverbially their home. The Spangled varieties showed to most advantage, the Silver-pencilled being the next approach to perfection. The *Bantams* were mostly good. In the *Variety* class a splendid pen of La Flèche fowls sent by Mrs. Blair deservedly outshone all rivals, the *Creve Coeurs* being the only near competition. The *Selling* class, limited to a prohibitory price of 30s., was well filled, contained capital pens, and many changed ownership.

In *Aylesbury Ducks*, as usual, Mrs. Seamons, of Aylesbury, left all in the rear. It seems as though, in spite of rivalry, this lady possessed some mode of management unknown to others. In *Geese* Mrs. Fergusson Blair took first prize and silver cup with a pen of perfect Greys weighing 52 lbs.; her mixed medley lot of all colours that won first at Birmingham so recently, however, were passed over entirely. The *Turkeys* were equal to any we have seen for some years past—a glorious lot, bringing to recollection the close approach of Christmastide, when family reunions bring happiness to all around, and smiles and blessings reign supreme. If, however, some of our forefathers, who presided at the festal board a century gone by, could behold a more than thirty-pound-weight Turkey poult smoking ready for the carving-knife on the 25th instant, perhaps their appreciation of the improvements of modern times in poultry would be as bewildering to their ideas as would be the recognition of our advance in locomotion. After all other reasonings, such facts tend more than all others to the popularity of poultry shows.

SPANISH (Black).—First, Right Hon. Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Second, S. Robson, Brotherton, Burton Salmon, York-shire. Highly Commended, R. Teebay, Fulwood, Preston; J. Short-hose, Newcastle-on-Tyne; J. W. Smith, Gundle, Northamptonshire; E. Brown, Sheffield. **Chickens.**—First and Cup, Right Hon. Viscountess Holmesdale, Linton Park, Staplehurst. Second, Master A. Ridpath, Edinburgh. Third, J. R. Rodbard, Wington, Bristol. Highly Commended, S. Corner, Fulwell, Monkwearmouth; J. Clews, Walsall; J. K. Fowler, Aylesbury; S. Robson; R. Teebay; H. Beldon, Bingley. Commended, J. Mills, Stockton; E. Brown, Sheffield.

DORKINGS (Coloured).—First and Cup, Mrs. F. Blair, Balthayock, Inch-maine, Incheure. Second, F. Benson, Boroughbridge. Highly Commended, Rev. J. E. Newton, Kirby, Stokesley; Mrs. F. Blair; J. Robinson, Gaistang; Right Hon. Viscountess Holmesdale, Linton Park, Staplehurst. Commended, Mrs. M. Seamons, Hartwell, Aylesbury; G. C. Whitwell, Kendal. **Chickens.**—First, T. E. Kell, Wetherby. Second, Right Hon. Viscountess Holmesdale. Third, Rev. J. E. Newton. Highly Commended, J. Bell, Thornton-le-Moor, Northallerton; D. Parsons, Cuerdon, Preston; Mrs. F. Blair; W. Dolby, Tunbridge Wells. Commended, F. Key, Beverley; F. Benson; Rev. J. F. Newton.

DORKING PULLETS (Any variety).—First, Mrs. F. Blair, Balthayock. Second, W. Dolby, Tunbridge Wells. Highly Commended, C. Pease, Southend, Darlington; Mrs. F. Blair. Commended, Mrs. Craigie, Chigwell; E. Whitwell, Darlington; J. Bell, Thornton-le-Moor.

DORKINGS (White).—First, Rev. G. Boynton, Lowthorpe Hall. Second, C. Pease, Southend. **Chickens.**—First and Cup, J. Robinson, Gaistang. Second, C. Pease. Highly Commended, C. Pease; E. Whitwell, Darlington; D. Parsons, Cuerdon.

COCHIN-CHINA (Cinnamon and Buff).—First, H. Bates, Birmingham. Second, C. T. Bishop, Lenton, Nottingham. Highly Commended, T. Stretch, Ormskirk. Commended, Captain Heaton, Lower Broughton, Manchester. **Chickens.**—First, C. T. Bishop. Second, Captain Heaton. Commended, T. Stretch, Ormskirk.

COCHIN-CHINA (Any other variety).—First and Cup, Mrs. F. Blair, Incheure. Second, T. Stretch, Ormskirk. Highly Commended, R. White, Sheffield. Commended, E. Tudman, Whiteburch, Salop. **Chickens.**—First, H. S. Stobart, Witton Tower. Second, J. Short-hose, Newcastle-on-Tyne. Highly Commended, T. Stretch; E. Tudman.

COCHIN-CHINA PELLETS (Any variety).—First, Captain Heaton, Lower Broughton. Second, Rev. G. Gilbert, Claxton, Norwich.

BRAMA POOTRAS.—First and Cup, R. Teebay, Preston. Second, J. Hinton, Hinton, Bath. Highly Commended, R. Teebay; Mrs. F. Blair, Incheure. **Chickens.**—First, R. Teebay. Second, Mrs. F. Blair. Highly Commended, R. Teebay; F. Powell, Knaresborough. Commended, W. L. Barclay, Leyton, London.

GAME (Black-breasted and other Reds).—First and Cup, J. Fletcher, Stoneclogh. Second, M. Billing, jun., Birmingham. Highly Commended, J. Fletcher; G. C. Whitwell, Kendal; G. W. Binns, Darlington; M. Billing, jun. **Chickens.**—First, J. Fletcher. Second, W. H. Wordsworth, Chesterfield. Third, H. Adams, Beverley. Highly Commended, G. C. Whitwell; M. Billing, jun. Commended, W. Bentley, Scholes, Cleckheaton; D. Parsons, Cuerdon.

GAME (Any other variety).—First, H. Adams, Beverley. Second, J. Fletcher, Stoneclogh. Highly Commended, W. A. Wooler, Sadberge Hall; H. Adams. **Chickens.**—First, J. Sunderland, jun., Coley Hall. Second, H. Adams.

GAME PULLETS (Any variety).—First and Cup, G. W. Binns, Darlington. Second, W. J. Cope, Barnsley. Highly Commended, W. A. Wooler, Sad-

berge Hall; C. Pease, Southend; H. Adams, Beverley; Miss J. A. Ackroyd, Bradford. Commended, W. A. Wooley; Miss E. Graham.

HAMBURGS (Golden or Silver-pencilled).—First, Right Hon. Viscountess Holmesdale, Linton Park, Staplehurst. Second, H. Beldon, Gilstead. Highly Commended, S. Smith, Northowram, Halifax; J. Dixon, Clayton, Bradford.

HAMBURGS (Golden or Silver-spangled).—First and Cup, G. Brooks, Huddersfield. Second, H. Beldon, Bingley. Highly Commended, T. Davies, Newport, Monmouthshire; J. Dixon, Bradford; S. H. Hyde, Ashton-under-Lyne. Commended, H. W. B. Berwick, Helmsley.

HAMBURGH CHICKENS (Golden-pencilled).—First, S. Smith, Northowram. Second, J. Powers, Biggleswade, Beds. Highly Commended, Hon. W. T. W. Fitzwilliam, Wentworth.

HAMBURGH CHICKENS (Golden-spangled).—First, S. H. Hyde, Ashton-under-Lyne. Second, B. Boynes, Kelghley, Yorkshire. Commended, T. Burch, Sheffield; H. W. B. Berwick, Helmsley.

HAMBURGH CHICKENS (Silver-pencilled).—First, Right Hon. Viscountess Holmesdale, Linton Park, Staplehurst. Second, C. M. Royas, Rochdale. Highly Commended, C. Moore, Poulton-le-Fylde, Preston; A. Nicholson, Wakeley, Sheffield. Commended, H. Pickles, jun.

HAMBURGH CHICKENS (Silver-spangled).—First, H. Beldon, Bingley. Second, J. Robinson, Garstang. Highly Commended, W. Cannon, Bradford.

POLANDS (Any variety).—First, H. Snowden, Great Horton (Golden Poland). Second, J. Dixon, Bradford (Silver Poland). Highly Commended, H. Carter, Holmfirth (Black Poland); J. Dixon (Golden Poland).

BANTAMS (Golden or Silver-laced).—First, H. Beldon, Gilstead. Second, J. Dixon, Bradford. Highly Commended, E. Yardley, Wisewood. Commended, G. Maples, jun., Wavertree, Liverpool.

BANTAMS (White or Black).—First, J. Dixon, Bradford. Second, Miss K. Charlton, Manningham. Highly Commended, W. T. Addison, Sunderland. Commended, J. Crossland, jun., Wakefield.

GAME BANTAMS (Any variety).—First and Second, J. Crossland, jun., Wakefield. Highly Commended, J. Cragg, Kendal; J. W. Morris, Rochdale; J. Barlow, Deptford, Sunderland; R. Hawksley, jun., Southwell, Notts; Miss E. Crawford, Southwell; D. Parsons, Cuerdon; M. Billing, un., Birmingham. Commended, H. Taylor, Chesterfield.

SINGLE COCKS.

DORKING (Any variety).—First, F. Benson, Aldbrough. Second, Mrs. F. Blair, Balthayock. Highly Commended, C. Pease, Southend; Hon. J. M. O. Powlett, Bedale; J. White, Warlaby. Commended, C. Pease.

COCHIN-CHINA (Any variety).—First, Captain Heaton, Lower Broughton. Second, J. Shorthose, Newcastle-on-Tyne. Highly Commended, H. W. B. Berwick, Helmsley.

GAME (Any variety).—First, J. Fletcher, Stoneclough. Second, A. Perkins, Darlington. Highly Commended, J. Fletcher; G. W. Binns, Darlington; H. M. Julian, Beverley; R. Swift, Southwell; H. Adams, Beverley; M. Billing, jun., Gravelly Hill; Miss J. A. Ackroyd, Bradford; H. Adams, Beverley.

GAME COCKEREL (Any variety).—First, G. W. Binns, Darlington. Second, M. Billing, jun., Gravelly Hill. Highly Commended, G. Jackson, Gairford; I. Wright, Ovenden, Halifax; C. Pease, Southend; D. Parsons, Cuerdon; A. Perkins, Darlington.

BANTAMS (Any variety).—First and Cup, C. Anklaad, Chesterfield. Second, W. Lawrenson, Allistree, Derby. Extra, R. M. Stark, Hull. Highly Commended, J. W. Morris, Rochdale; R. Swift, Southwell; J. Crossland, jun., Wakefield.

DUCKS (Aylesbury).—First, Mrs. M. Seamons, Aylesbury. Second, J. Smith, Breder Hills, Grantham. Commended, Rev. J. G. Milner, Bellerby. **Ducklings**.—First, Mrs. M. Seamons. Second, R. M. Stark, Hull. Highly Commended, Mrs. M. Seamons. Commended, Hon. J. M. O. Powlett, Bolton Hall.

DUCKS (Rouen).—First, M. Redhead, Strickland Gate, Kendal. Second, C. Pease, Southend. Highly Commended, J. Dixon, Bradford. **Ducklings**.—First, J. R. Rodbard, Wrigton. Second, C. Pease. Highly Commended, C. Pease.

DUCKS (Any other variety).—First, D. Parsons, Cuerdon (Grey Call). Second, J. B. Jessop, Hull (Buenos Ayrean). Highly Commended, S. Burn, Whitby (Buenos Ayrean).

GESE.—First, Mrs. F. Blair, Balthayock, Inchmartine. Second, Mrs. M. Seamons, Aylesbury. Highly Commended, Mrs. M. Seamons; C. Pease, Southend; T. Jolly, Warlaby; Mrs. F. Blair. **Goslings**.—First, Mrs. A. Wooley, Yarm. Second, J. Dixon, Bradford.

TURKEYS.—First, J. Smith, Breder Hills. Second, Mrs. F. Blair, Balthayock. Highly Commended, Mrs. A. Guy, Eaton, Grantham. Commended, C. Pease, Southend. **Poultis**.—First, J. Smith. Second, C. Pease. Highly Commended, Mrs. Bolland, Bedale; Mrs. A. Guy.

SINGLE TURKEY COCK.—First, C. Pease, Southend. Second, Mrs. A. Guy, Eaton. Highly Commended, Mrs. F. Blair, Balthayock.

ANY OTHER DISTINCT BREED.—First and Second, Mrs. F. Blair (La Flèche and Crève Cœur). Highly Commended, W. W. Nicholls, Sale, near Manchester (Black Hamburg); J. Dixon, Bradford (Japanese Bantams); H. Beldon, Gilstead (Black Hamburg).

SELLING CLASS.—First, E. Whitwell, Darlington (Grey Dorkings). Second, J. Dixon, Bradford (Golden Poland). Highly Commended, E. Whitwell (Grey Dorkings); J. White (Grey Dorkings). Commended, W. L. Mason, Chesterfield (Grey Game Bantams); J. Dixon (Black Poland); J. White, Warlaby (Silver Grey Dorkings and Grey Dorkings).

EXTRA STOCK.—Highly Commended, C. Pease, Southend (Golden Pheasants). Commended, C. Pease (Swans).

The Judges of poultry were George Andrews, Esq., of Dorchester, and Edward Hewitt, Esq., of Sparkbrook, Birmingham.

THE LEEDS POULTRY EXHIBITION.

This Society has now been established for four years, in connection with an Agricultural Show for fat cattle. Each year, we are happy to say, its success has proved regularly

progressive, but certainly its progress this year has been still more apparent than ever. The Show took place in a temporary erection, as heretofore, but it now appears to be likely before another season a contemplated permanent and suitable building will offer still greater advantages to this Society.

Of the *Grey Dorkings*, with the exception of the winning pens, we can say but little, as the condition in which the generality of the birds in this class were shown was inferior, but Mr. Benson's first and second prize birds would have been a very creditable addition to any poultry exhibition; they were the same in colour as Captain Hornby's well-known strain. The like observation holds good also with the *Black Spanish* fowls—viz., condition was wanting throughout. In *Cochins*, all colours competing together, Partridge-feathered ones exhibited by Elijah Smith, of Manchester, took the precedence. So good was this pen, that the well-known Captain Heaton's stock had to take second place, and this Partridge pen were the only birds that competed closely with the trio of *Black Polands*, to which the Society's Silver Cup for the best pen of Any variety of poultry exhibited was awarded. Captain Heaton's Buffs were well shown, but appeared to suffer from being too frequently exhibited. In the *Game* fowls, *Black* or *Brown Reds*, there was considerable competition, the *Brown Reds* being as a whole the most perfect variety. A splendid *Brown Red* pen took first position. In this class as good a pen of the same colour as any one could wish to see, and decidedly not inferior in character to even the winners, was compulsorily disqualified by the arbitrators, one of the hens being suffering severely from "roup." The cock in this pen was naturally a very perfect one, but by some accident or other had lost a spur. Class 37 was for Any variety of Game except *Reds*, and the result was an exhibition of many pens of the best *Duckwings* we have seen for years past; in fact, as close-feathered well-built birds as ever even a "cocker" could desire. This perfection of feather is but seldom attained by this breed of Game fowls. In the *Single Game Cock* class, a noble *Black Red* headed the prize list, the third prize was also of this colour, the second prize being given to a *Brown Red*. It is well known to connoisseurs of poultry that the neighbourhood of Leeds has for a long term of years been famous for its *Hamburghs*, and certainly the collection now sent fully maintained its high repute. The *Spangled* varieties were, perhaps, equal to any classes that have been shown at any poultry show this year. Not only were the winning pens of the highest merit, but it would have been difficult to point out even a single indifferent pen in the whole of the classes. The great feature of the Leeds Show, however, strangely enough, proved to be the *Poland* class; and it was the unanimous opinion of the Judges that so good a number and variety of *Polands* in any one show they never before met with. It was the first-prize birds in this class (*Black Polands* with white crests), that secured the Society's silver cup for the best pen of poultry shown. The class for "Any variety or cross" was almost exclusively made up of *Black Hamburghs*, as no less than twelve pens of this useful breed put in an appearance. Nearly every pen was good. The *Black Bantams* were not equal to our expectations. In the *White Bantams* the competition was better; in this class a somewhat singular and laughable incident occurred, as decidedly the best pen was disqualified for an attempted imposition, that shows at least the ingenuity of poultry amateurs in the northern counties. The exhibitor, finding his birds the worse for moulting, actually attempted to supply nature's temporary deficiency by refixing, very artistically too, the tail-feathers with cobbler's wax! To the practical eye of one of the Judges, Mr. Hewitt, of Birmingham, this cunning device was instantly apparent, and a close inspection, when the fowls at his desire were taken out of the pen, removed all doubts on the subject. Having again and again proved that simply the disqualification of a pen for such unjust practices does but little, if anything, to prevent their owners from again attempting the like frauds on honest competition, it appears most probable an exposure of names as well as trickster habits, may do better to remedy the evil in future than the mere loss of a prize only, and, therefore, we publish the name of the exhibitor—Mr. Frederick Hardy, of Quarry Gap, Bradford. The *Game Bantams* were not nearly so good as we hoped for; and singularly enough, the

best Game Bantams in the Show consisted of several pens entered in the wrong class.

The *Geese, Turkeys, and Ducks* were decidedly good—in fact, not a single variety was unrepresented, and that, too, by the best of birds.

The *Pigeons* at Leeds were a very interesting and excellent portion of the Exhibition. We particularly noticed some especially good White Pouters, Duns, Carriers (which, by-the-by, were quickly snapped up at not a half of their value directly the Show opened), and many varieties of beautiful Tumblers, though, strange to say, the Almonds were not good. The White Owls were perfect gems; and the Black, as also the White, Trumpeters were scarcely less worthy of notice. The prize Fantails were particularly good, but shown in the dirtiest feather we ever yet saw Pigeons. The Turbits were of many colours, and proved a capital class. The Jacobins were also superior. The class for "Any other variety of Pigeons" was so well filled as to induce the Judges to award an extra equal first prize.

Among the oddities of the Show, in the class for any other variety of poultry a pair of the common Barn Owls were shown. The novelty of their appearance interested the visitors, but the poor Owls evidently considered themselves in the wrong class, as much so as did the Arbitrators who officiated.

The weather, though windy in the extreme, was fine, and, consequently, there was not any lack of visitors.

The Club gave a Silver Cup for the best pen of poultry in the Show ground, in addition to the money prizes.

DORKINGS.—First and Second, F. Benson, Aldborough, Boroughbridge. Third, S. Pickard, Wakefield. Commended, G. Taylor, Hunslet.

SPANISH.—First, D. Illingworth, Burley, Otley. Second, T. Greenwood, Dewbury. Third, J. Siddal, Halifax.

COCHIN-CHINA.—First and Third, E. Smith, Middleton. Second, Captain Heaton, Lower Broughton. Commended, Captain Heaton; F. M. Hindle, Haslingden; T. Wrigley, Tongue, Middleton.

GAME (Black-breasted and other Reds).—First, H. Adams, Beverley. Second, E. Beldon, Bingley. Third, W. Boyes, Beverley.

GAME (Any other variety).—First, H. Adams, Beverley. Second, H. Snowden, Bradford. Third, J. Hodgson, Bradford. Commended, J. Harrison, Leeds; J. Anderson, Bingley; J. Rinder, Sheepscar; T. Hartley, Gomersal.

GAME COCK (Any variety).—First, G. Pounder, Kirby Moorside, York. Second, R. Adams, Beverley. Third, M. Billing, jun., Birmingham. Highly Commended, R. Hemingway, Shelf, Halifax; H. Adams. Commended, T. Suddick, Dudley Hill; W. Garforth, Drighlington.

HAMBURG (Gold-pencilled).—First, J. Lancashire, Chadderton, Lancashire. Second, W. Cannan, Bradford. Third, R. Hemingway, Halifax. Highly Commended, J. Dixon, Bradford. Commended, T. Wrigley, jun., Middleton.

HAMBURG (Silver-pencilled).—First, J. Dixon, Bradford. Second, H. Pickles, jun., Earby, Skipton. Third, R. Hemingway, Halifax. Commended, E. Beldon, Bingley; J. Platt, Bolton, Lancashire.

HAMBURG (Gold-spangled).—First, J. Newton, Salsden. Second, T. Birdsall, Woodhouse Carr. Third, J. Hope, Wernath, Oldham. Highly Commended, J. H. Hepper, Upper Wootley. Commended, J. Dixon, Bradford; J. H. Hepper; W. Cannan, Bradford.

HAMBURG (Silver-spangled).—First, J. Lancashire, Chadderton. Second, J. Newton, Salsden. Third, E. Stephenson, Bowler, Middleton. Commended, J. Dixon, Bradford; J. Jowett, Morley, Leeds; E. Beldon, Bingley.

POLAND (Any variety).—The Society's Silver Cup, value six guineas, for best pen of poultry of any breed exhibited and First, H. Carter, Upperton, Holmfirth. Second, W. Newsome, Bingley. Third, J. Dixon, Bradford. Highly Commended, J. Dixon; W. Newsome. Commended, D. Illingworth, Burley, Otley.

ANY VARIETY NOT PREVIOUSLY CLASSED.—First, J. Hope, Oldham (Black Hamburgs). Second, E. Beldon, Bingley (Ptarmigans). Third, E. Leech, Rochdale (Brahma Pootras). Highly Commended, J. Hind, Bingley (Black Hamburgs). Commended, W. Harker, Cottingley, Bingley (Black Hamburgs).

BANTAMS (Black).—First, E. Beldon, Bingley. Second, H. Gornal, Farnley.

BANTAMS (White).—First, J. Harrison, Wakefield. Second, A. & B. Farrar, Bramley.

BANTAMS (Game).—First, R. Smith, Hull. Second, C. Templar, Ackworth. Commended, T. Carr, Benthams; H. & G. Newton, Garforth.

BANTAMS (Any variety).—First, W. J. Cope, Earnley (Pekin Bantams). Second, R. M. Stark, Hull (Gold-laced Bantams).

GUINEA FOWL.—First, O. A. Young, Driffield. Second, Lady Hawke, Pontefract. Third, J. Dixon, Bradford.

TURKEYS.—First, R. M. Stark, Hull. Second, J. Dixon, Bradford. Third, T. Richardson, Barnsley.

GESE.—First, Mrs. Appleyard, Thorp Arch. Second, O. A. Young, Driffield. Third, J. Dixon, Bradford. Commended, G. Yates, Bradford.

DUCKS (Aylesbury).—First, T. E. Kell, Wetherby. Second, E. Leech, Rochdale. Third, F. M. Hindle, Haslingden. Highly Commended, F. M. Hindle; E. Leech.

DUCKS (Rouen).—First, J. Dixon, Bradford. Second, E. Leech, Rochdale. Third, J. Ward, Drighlington.

DUCKS (Any variety).—First, J. R. Jessop, Hull (East India Ducks). Second, R. M. Stark, Hull (Wild Ducks). Third, J. Dixon, Bradford.

EXTRA POULTRY.—First, J. Dixon, Bradford (Mandarin Ducks). Second, E. Leech, Rochdale (Malays). Third, F. Hardy, Bradford (Chinese Silver Pheasants).

PIGEONS.

CARRIERS.—First, W. Watson, Beverley. Second, J. Firth, Dewsbury. **POUTERS.**—First, E. Horner, Harewood. Second, F. A. & W. J. Stead, Leeds.

TUMBLERS (Almond).—Second, H. Yardley, Birmingham. First withheld. **TUMBLERS (Any variety).**—First, J. R. Jessop, Hull. Second, C. Hodgkinson, Burley, Otley. Highly Commended, F. Elze, Bayswater; H. Yardley, Birmingham; A. Wilkinson, New Leeds. Commended, T. Birdsall, Woodhouse Carr; F. A. & W. J. Stead, Leeds; A. Wilkinson.

OWLS.—First, H. Yardley, Birmingham. Second, F. Elze, Bayswater. Highly Commended, F. A. & W. J. Stead, Leeds.

FANTAILS.—First, F. Elze, Bayswater. Second, F. A. & W. J. Stead, Leeds. Commended, T. Birdsall, Woodhouse Carr.

BARBS.—First, H. Yardley, Birmingham. Second, J. D. Danty, Leeds. Commended, J. R. Jessop, Hull.

TURBITS.—First, J. W. Edge, Birmingham. Second, H. Yardley, Birmingham. Highly Commended, T. A. & W. J. Stead, Leeds; F. Elze, Bayswater.

JACOBINS.—First and Second, T. Ellington, Woodmansey, Beverley. Highly Commended, T. Birdsall, Woodhouse Carr.

TRUMPETERS.—First, F. Key, Beverley. Second, S. Robson, Brotherton.

NUSS.—First, F. Key, Beverley. Second, F. Elze, Bayswater. Highly Commended, J. W. Edge, Birmingham.

ANY OTHER VARIETY.—Equal First, H. Yardley, Birmingham. Second, J. W. Edge, Birmingham. Highly Commended, J. Pollard, Leeds; J. Wade, Bank, Leeds. Commended, T. Birdsall, Woodhouse Carr.

The Judges officiating at Leeds were—Mr. Edward Bond, of Leeds; Mr. Thomas Challoner, of Whitwell, Chesterfield; and Mr. Edward Hewitt, of Sparkbrook, Birmingham.

YORKSHIRE FAT STOCK AND POULTRY SOCIETY.

THE seventh annual Exhibition of the above Society was held at York on the 2nd, 3rd, and 4th inst., and went off very satisfactorily. There was a large increase in the poultry over those shown in former years; and it promises now to become one of the principal poultry shows in England.

The following is the list of prizes awarded:—

DORKING (Any colour).—First and Second, F. Benson, Aldborough. Third, J. White, Walsby. Highly Commended, R. M. Stark, Hull. Commended, R. Gell, Grimston.

SPANISH.—First, G. Jackson, Penley Grove Street, York. Second, J. Dixon, Bradford. Third, C. Powell, Kaarsborough. Highly Commended, G. F. Jones, Bootham, York.

COCHIN-CHINA (Cinnamon or Buff).—First, T. H. Barker, Hovingham. Second, H. W. B. Berwick, Helmsley.

COCHIN-CHINA (Any other variety).—First and Second, J. Bell, Thirsk.

GAME (Black-breasted and other Reds).—First, Miss E. Beldon, Gilstead, Bingley. Second, J. Firth, Halifax. Third, T. Dyson, Pelson Lane, Halifax. (All the class commended.)

GAME (Any other variety).—First, T. Hartley, Field Head, Gomershall, Leeds. Second, J. Firth, Lily Lane Mills, Halifax. Third, H. Whiteley, Womersley, Pontefract. Highly Commended, J. Rinder, Sheepscar, Leeds. Commended, Miss A. Hodgson, Illingworth, Halifax.

HAMBURG (Golden-pencilled).—First, Miss E. Beldon, Gilstead, Bingley. Second, J. Dixon, Bradford. (All the class commended.)

HAMBURG (Silver-pencilled).—First, J. Dixon, Bradford. Second, D. Illingworth, Burley, Otley. (All commended.)

HAMBURG (Golden-spangled).—First, T. and J. Dobson, Pickering. Second, W. Cannan, Adolphus Works, Bradford. (All the class commended.)

HAMBURG (Silver-spangled).—First, Miss E. Beldon, Gilstead, Bingley. Second, W. Cannan, Adolphus Works, Bradford. (All the class commended.)

POLAND (Any variety).—First, Miss E. Beldon, Gilstead, Bingley. Second, R. M. Stark, Claremont Terrace, Hull. Highly Commended, J. Dixon, Bradford.

ANT FARMYARD CROSS, OR OTHER VARIETY NOT PREVIOUSLY CLASSED.—First, F. E. Powell, Kaarsborough. Second, W. Cannan, Adolphus Works, Bradford. Third, J. Carey, Heslington, York. (All the class commended.)

GUINEA FOWL.—First, Lady Hawke, Womersley Park, Pontefract.

BANTAMS.—First, J. Braddock, York. Second, H. & G. Newton.

BANTAMS (Black or White).—First, W. Cannan, Bradford. Second, W. Baynes, Middleton, Pickering.

BANTAMS (Any other variety).—First, Miss E. Beldon, Gilstead, Bingley. Second, J. Dixon, Bradford.

TURKEYS.—First, Mrs. A. Guy, Eaton, Grantham. Second, R. M. Stark, Hull. Highly Commended, J. Dixon, Bradford.

GESE.—First, O. S. Young, Driffield. Second, C. Pease, Southend, Darlington. Highly Commended, J. Dixon, Bradford.

DUCKS (Aylesbury).—First, T. E. Kell, Wetherby. Second, R. M. Stark, Hull. Highly Commended, O. S. Young, Driffield. (All the class commended.)

DUCKS (Rouen, or any other variety).—First, J. Dixon, Bradford. Second, Miss E. Beldon, Gilstead, Bingley. (All the class commended.)

JUDGES.—Messrs. J. O. Jolly, Accomb, York; M. Hunter, Green Hammerton, York; G. Jackson, Penley Grove Street, York; and Alexander Cattley, Tower Street, York.

THE CHIPPENHAM POULTRY SHOW.

THE town of Chippenham, Wilts, possesses many advantages as a place for the exhibition of poultry, for the Great Western Railway passes through it, connecting it

with a very large portion of the whole of England; then for some years past, a railway has been opened to Salisbury, and by it the extreme south has been joined to Chippenham; and only the other day a railway from Calne commenced running into the Chippenham Station. As another advantage let me add, that the station is very large, and, however many pens of poultry might arrive, at any rate there would be abundance of room for them all. Then, too, the place for exhibition is not very far from the station; and as I heard an exhibitor remark, "Mr. H. Gale, who has the care of the poultry, is among the most civil and careful of men." Yet, strange to say, that with all these things in its favour, the Show at Chippenham (which is a very stirring striving town, by no means "a grass-grown place of the ancients"), is as yet among the smaller shows, perhaps this arises from its not being advertised. For some years past poultry has been regularly exhibited at the annual meeting of the Agricultural Association, held in the spacious covered cheesemarket, behind the new hall.

About the origin of this Show there is a little tale to tell. A gentleman in advance of his neighbours in poultry matters, suggested at a meeting of the Agricultural Society that prizes should be awarded for good specimens of the domesticated fowls. "What!" said another gentleman, "would you give a prize for a goose hiss-hiss?" This was uttered in perfect good humour, though with a feeling of real surprise. But the gentleman stood his ground and said manfully, "Yes, for a good goose, certainly." Hence arose the Chippenham Poultry Show. "All honour to those who try."

This year there were ninety-nine pens in all. Those of the fowls were arranged in the Market House; those of the Turkeys, Geese, and Ducks, at the sides of the wide space at its entrance, in which, by the way, there would be abundance of room for a middle row should the Show become larger.

As usual at Chippenham, the *Game* was the predominant class, there being twenty-two pens and seven single cocks. I was glad to see this truly English breed, and by far the most beautiful of all fowls, in such high favour. Formerly, when cock-fighting was customary, it was impossible to sever the idea of cruelty from the sight of a Game cock; now, happily, our admiration has no such drawback. Almost all the pens contained good birds, so that this prize was the blue ribbon of the Show. The first prize was obtained by Mr. H. Waller, of Calne; the second went to a Chippenham breeder, Mr. H. Stevenson. Mr. A. Heath's prize bird among the single cocks was almost perfection, so neat, so close-feathered, and in head so snake-like. The *Dorkings* mustered strongly; but I was sorry to see only two pens of *Spanish*, two of *Golden-pencilled Hamburgs*, and two of *Silver-pencilled*; and worse still, no entry whatsoever of *Silver-spangled*. Let me recommend these classes to fowl-lovers in and near Chippenham. Why should not some one at least adopt as his fancy those striking-looking birds, and excellent layers into the bargain, the *Silver-spangled Hamburgs*? he would have a great chance of success, and gratify the eyes of the many visitors at the Show. Mr. Jacob Phillips showed a good pen of *Polands*; there being four pens in this class it was represented better than we had hoped, as *Polands* seem at most shows on the decline. Among the *Cochins*, Miss J. Milward took first prize; and among "Any other distinct or cross breed" Dr. Colborne, of Chippenham, exhibited a pair of *Crève Cœur*, a new sort at Chippenham, the cock a very "Diabolus" in appearance but not in disposition, as his owner tells me. Near *Diabolus* was a brother fiend, in looks at least, Mr. J. J. Fox's *Malay Cock*, but still all praise to Mr. Fox for keeping up an old and once highly esteemed breed. The *Malay Cock* might aptly possess the soul which once inhabited the body of a *Romish Inquisitor*. "Gratify me, please, with another sight of the rack!" seems to say Mr. *Malay*. And, now, for the pretty pretty *Bantams*, which mustered stronger than ever before—there were ten pens. Doubtless Mr. R. Brotherhood's great success with his now famous *Blacks*, which began their career of conquest at Chippenham, has acted as an incentive to his neighbours. The prize *Black Reds*, Mr. F. Bailey's, of Calne, were good; while Mr. F. Phillips' *Duckwings* were as to the hens very excellent, but the cock was scarcely their equal. As to the *Turkeys*, *Geese*, and *Ducks*, the first were good, the second very good,

the last not so very good; the *Blacks* (Miss Milward's) and the *Rouens* being better than the *Aylesburys*.

As I walked round and round enjoying the sight of the beautiful birds, thus brought so pleasantly before me—for a poultry show must be allowed on all hands to be a pretty sight—I could not but wish that prizes were offered at Chippenham for *Pigeons*; they are always attractive, and ladies especially gather round their pens. At one show I could not get my fill of enjoyment out of the *Pigeons*, for alas! *crinoline* barred my vision. Indeed, I would venture to prophesy, that commercially the Association would be no loser by offering fair prizes for these beautiful birds, as they would be sure to "draw." Let me just add, in conclusion, that I had the pleasure at this Show of making Mr. Rodbard's acquaintance, who, after the prizes had been awarded (please to mark the *after*, good exhibitors), most kindly walked round with me, and we discussed the merits of various pens, and as poultry-lovers are wont to be, we were friendly at once. WILTSHIRE RECTOR.

WASPS AS PAPER-MAKERS—MALES OF INSECTS HAVE NO STINGS.

I AM indebted for the following very interesting particulars regarding wasps to my friend Mr. F. Smith, President of the Entomological Society. It is completely decisive on the question recently mooted in THE JOURNAL OF HORTICULTURE with regard to the non-possession of stings by male wasps.—A DEVONSHIRE BEE-KEEPER.

"I think I see in the cells of bees a mode of construction quite different to that of the wasps, and should expect to do

so when we consider the fact that bees use a material soft and ductile at all times; wasps very different materials in different genera. All are paper-makers, but some manufacture tissue, others I must call note-paper-makers, then we have brown-paper-makers, and we have pasteboard-makers; the latter construct bell-shaped nests that often swing on the branch bell-wise. These wasps complete the bell and also the floors, upon which they subsequently build cells, before a single cell is formed, as above, or, probably, in most cases when four or five floors are laid down, they begin at the top to erect a few cells while the lower chambers are being finished.

"No male wasp has a sting, neither has the male of any known species of insect."

FOUL BROOD.

I MUST fling my experience into the scale of those who think and assert that foul brood is a disease, and not peculiar to the Ligurian race of bees. Without doubt I had it in one of my hives this year, and I entertain as little that the disease once was the cause of destroying a hive of mine

in Yorkshire. My diseased hive of this year was not experimented upon. I do not see how its brood could have become chilled. The bees were in a small hive of thick wood, placed in a bee-house well protected with asphalt, and packed round in the interior with hay not removed till the swarming season. My bees are all of the English sort. I say, therefore, to "INQUIRER," and others, that I range on the side with those who imagine that a foul disease exists and rages at times amongst our favourites, and that our thanks are due to those who have opened our eyes to its existence. There can be no question either, but that most of the pollen lately gathered has been from the ivy. Such a profusion of bloom on that "rare old plant, the ivy green," as exists this year, has never before been remarked upon by—A HAMPSHIRE BEE-KEEPER.

If Mr. Lowe in his late escapade awkwardly trod upon sensitive corns, I am sure, from the kicks received on every side by himself, he has fully atoned for the tone of his articles. I cannot believe that Mr. Lowe meant to offend; and no one from his remarks, which were more empiric than logical, and more facetious than hurtful, will think one whit less highly of Mr. Woodbury and his scientific apiary. But when truth is to be investigated, statements must be met by counter-statements supported by evidence.

And now that Mr. Lowe has amused us with a fling at experimentalists, I should like him to measure his strength with Mr. Woodbury in facts and arguments on the "foul brood" affection, which has a very disagreeable odour to all lovers of bees, and carries along with it a most irritating virus.

Mr. Lowe has a good case, let him apply himself to it; a vast mass of evidence may be adduced in support of his views.

On a less important subject than "foul brood," I would not object to a little kind abuse; but where extermination is threatened, by all means let our energies be applied to the cause, extent, and cure of the evil.—A LOOKER-ON.

HOW TO REMEDY CROOKED COMBS IN A FRAME-HIVE.

Will the "DEVONSHIRE BEE-KEEPER," or any of your correspondents inform me which is the best way to secure straight combs in Woodbury-bar frame-hives, when guide-combs are not obtainable? I have run melted wax along my ribbed bars, and I thought this would cause the bees to build straight combs, but to my great disappointment the bees have built crooked combs, as though there had been no bars, which makes it difficult to extract the bars from the hive.—S. H.

[You have already adopted the best means of insuring the formation of straight combs when guide-combs are not obtainable—means that would probably be successful in nine cases out of ten. As, however, they appear to have failed in the present instance, you had better leave matters as they are till next year. During the middle of a fine day in April the bees should be driven into an empty hive, when such combs as require it may be cut out, straightened, and arranged symmetrically in the frames and replaced in the hive, to which the bees should then be returned. Full directions for performing this operation were given in No. 75 of THE JOURNAL OF HORTICULTURE.—A DEVONSHIRE BEE-KEEPER.]

OUR LETTER BOX.

BOARDED FLOORS FOR POULTRY-HOUSES (M. R. P.).—They are objectionable, because all hard flooring upon which fowls have to descend from the perches is liable to cause corns and other injuries to their feet. Our charge for advertisements is 6d. per line.

VULTURE HOCKS (An Inquirer).—Vulture-hocked fowls have feathers projecting from below the knee joint, and sticking out behind, as the vulture and some other birds of prey. It is considered a fault in Brahma Pootras when much developed. In many good specimens it exists in a trifling degree and is not then much noticed.

EARLY CHICKENS (Ereclstior).—If you intend your fowls for the London market, you must confine yourself to the Dorking, and must have your chickens ready for sale from the middle of April till the middle of June, or the beginning of July. They should be from eighteen to twenty weeks old, and provided they are not older, the larger they are the better. Cochins will not do, because they have yellow legs, nor will any do that have black, blue, or green legs. They should be fatted, killed and picked clean, sent up very fresh, and packed in a basket or crate with stiff wheat straw.

COLOUR OF ROSEN DUCK'S BILL (A Constant Reader).—The Rosen Duck's bill should be the fac-simile of the wild Duck's. It should be yellow at the tip and round the edges, brown in the centre—in colour, but not in shape, like the Bean Goose, and it is said that bird gained its name from the bill being coloured like a horse bean.

BIRCHEN GREY GAME FOWLS (Inhabitor).—When Judges look at Birchen Greys they do not ask themselves how they are bred. They are birds of colour, and unless correct they are passed over. We have seldom seen more than two or three pens of such at Birmingham, and the competition is too hard for them. The Birchen Grey may be bred between the Black Red and the Silver Duckwing.

POULTRY'S FEATHERS CHANGED IN COLOUR (A. N. B.).—Fowls will sport in moulting. We have had Spanish moult partly white, and re-moult black. There is no reason why your Dorking hen should not do the same. When a fowl is becoming white from age there is no hope of any return to dark plumage; but at any other period it may be looked for.

BANTAMS WITH DOAKINGS (Idem).—We keep Bantams with large breeds without any difficulty. We believe you may do the same, but not with the smaller, as Game, Hamburgs, &c.

PELLETS (G. Whittington).—They are probably of no value. Put them up for sale at one of Mr. Stevens's auctions, and then you will ascertain what fanciers think of them.

WHITE-FOOTED BANTAMS (F. H. P.).—They may be double or single-combed. The former are preferred always. They should not be vulture-hocked. The latter appendage belongs to what are called Bristled Bantams. They are feathered to the toes and very vulture-hocked.

SCOTCH BAKERS (J. W.).—The "Poultry Book" is to be had at our office. Bakes are now very scarce. The best we have seen or know of, belong to the Hon. Georgina de Flahant, Tullymill, Kincardine-on-Forth. That lady may have some to spare. They are good layers, and excellent sitters and mothers.

BLACK BANTAMS.—An Orfordshire Rector presents his compliments to "A WILTSHIRE RECTOR," and thanks him for his letter. He would not like to make such a proposal to the Editors as that referred to, as in carrying out the arrangement an unwarranted confidence might be induced.

PEN OF GAME FOWLS (H. J.).—Two pullets must match in every particular. A Black-breasted Red cock must not have one red feather in the breast.

POULTRY FEATHERLESS UNDER THE BEAK (H. J. P.).—Rub the bare place with compound sulphur ointment. We do not think it comes from insects. If it does, and the bird has not access to dust, provide him with it. It will kill vermin.

DUCKS AND GEES AT BIRMINGHAM (Quack).—We do not know who judged the Ducks at Birmingham. We thought them a very fine class, and well judged. The Rouen according to our idea, should be in colour the counterpart of wild Ducks. At this season of the year it is easy to get wild Ducks and compare them. We believe the prizes are given for Grey and Mottled and in these pens the gender is almost always white. Weight is an essential point in Geese, and but a few years ago any approach to white was held superior to grey. The introduction of the Toulouse has altered this, but in any market where Geese are sold for the table, a Grey is less valuable than a White or Pied bird. Geese are table, not feather birds. High condition is impressed on the Judges as desirable, and so far as we could judge, the first-prize pen enjoyed it.

BLACK HANEBRODS AND DUCKS AT BIRMINGHAM (A Subscriber).—We saw the classes in question, and were perfectly satisfied with them. It is very possible that sometimes Ducks are mixed with ducklings, and old fowls with chickens. Subscriber would himself be deceived sometimes.

NORFOLK ORNITHOLOGICAL SOCIETY.—I should feel greatly obliged if you would correct an error which appears in your Number of November 24th—viz., in the undermentioned awards:—Canaries, &c.—Norwich (Clear Yellow).—First and Second. Norwich (Clear Buff).—First. Norwich (Marked and Variegated Yellows).—First. Goldfinch (Miles, Mealy).—First. Goldfinch (Jonque).—First and Second. *British Birds*.—Skylark and Goldfinch, Siskin or Aberdevine. *Foreign Birds*.—Wax Bill. *Poultry* (Class 123).—Game Bantams (Duckwings).—Second. All these are placed to the credit of Mr. S. Waters, of Ipswich, instead of myself.—W. WALKER, Hyde Street, Winchester.

PARROT AND DOG (An Old Subscriber).—With reference to the Australian Parrot we fear not much can be done except keeping it warm, and most probably it will regain its feathers. The Dog should be kept short of food in order to reduce its fat. Instead of mangle give it bread and milk, and a little broth in turn, and occasionally a tea-spoonful of castor oil.

WANTS OF AMATEURS (Epimæ).—We have read your communication, and communications from others, upon the subject of setting up a column for amateurs to make known their wants to each other, but find there are insuperable difficulties. Our advertising columns must be open to all without any attempt at distinction; and no amount of remuneration would induce us to sanction the belief that all who were included in an amateurs' column were trustworthy. An advertisement is the legitimate mode of making known the requirements of either the buyer or the seller, and neither the one nor the other need be criticised if common caution be adopted. As suggested in our columns to-day, a third party might hold the money until inspection had been obtained and the negotiation was concluded.

EGGSET.—We have no objection to insert your communication, but the time has come when it is desirable for us to have your real name and address.

LONDON MARKETS.—DECEMBER 14.

POULTRY.

There is a slight improvement in the market. The supply, as is always the case before Christmas, is much less, and good quality finds a ready sale at better prices.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 43.2°, and its night temperature 30.5°. The greatest heat was 58°, on the 25th, 1827, and 25th, 1855; and the lowest cold, 1° below zero, on the 28th, 1860. The greatest fall of rain was 1.13 inch.

MATERIALS USED IN FORMING COMPOSTS.

SINCE the time that man was ordained to earn his bread by the sweat of his brow, many and varied have been the means adopted to lighten the labour, and to increase the capabilities of certain portions of the earth's surface to bring forth trees, herbs, or fruits in greater abundance than by her own unassisted power she would have been able to do. The tilling of the ground in the first place, to render it a fit repository for the seeds of the plants mostly wanted, no doubt led to the addition of such decayed substances as were supposed to be in the way, and these, being buried to get rid of them, gave evidence by the improved character of the crops that the addition was to their liking, and, probably, more care would be taken next time to distribute the refuse matter more regularly over the ground. Such a beginning is very likely to have been the first application of manure, and it is not unlikely that examples of it may yet be met with in countries but recently, or even only now, commencing that course of cultivation which it is said all are destined to go through.

Assuming this primitive mode of burying the decayed substances collected about the homestead to have been the commencement of that system of manuring which has of late years engaged the attention of the most learned men of the age, it certainly stands forth in strong contrast with what is said to have been the custom with some American farmers, who, having allowed their dung-heaps to accumulate before their doors to such an inconvenient extent as to be no longer endurable, preferred as a remedy building new sheds and dwellings at other places rather than to remove the dung. Whether this was so or not, there is little doubt but that much greater waste of manurial substances takes place in countries but thinly inhabited than in those in which land and its produce are of great value. The manuring of some lands is, however, in some countries undertaken by Nature herself, and the labour of the husbandman is of a monotonous character, differing but little one century after another. Of this class is the flat but rich corn-producing country of Egypt, which is more indebted for its fertility to the river Nile than to any of the numerous races of people which have inhabited it for the last twenty centuries or more.

Modes of cultivation, however, requiring more industry on the part of the husbandman have been continued for very long periods in certain densely populated districts that have for many centuries possessed a great amount of civilisation—as, for instance, the valley of the Ganges and other Indian rivers, where a certain amount of manual

labour is most liberally met by natural assistance, which a long course of years has proved may invariably be depended on. But in this case it sometimes happens that the artificial process adopted bears a strong resemblance to manuring. Irrigating the Rice fields with water which has been stored away for that purpose is only another form of using the materials which Providence has placed within our reach; and the supply being abundant, the skill to collect and use it was only wanting. Nature having been prodigal in other of her blessings as well.

A much greater amount of industry is wanted in countries less favourably placed by Nature; but fortunately the inhabitants of such countries have generally been found equal to the requirements of this case. Inhabiting a climate less favourable to vegetation, they have to use more exertion to extract from mother earth those productions they so much want; and with the sweat of the brow the mind is brought to bear on the subject, and new and improved modes of cultivation are brought into exercise, or it may be that a long series of experiments on the part of those who have passed away may have established a set of rules for the guidance of their successors, and from which it is not safe to depart. To the latter cause much of the cultivation of China may, doubtless, be traced; and that empire, though no longer progressive according to the opinions of those who have lately visited it, must at some former time have been so, or the high state of cultivation it has arrived at would never have existed. Perhaps the most remarkable feature in the cultivation of the land by that singular people, the Chinese, is the careful and judicious mode in which they collect and use everything in the shape of manure; and as we have reason to believe that many of the lands now in cultivation have been so for many, many generations, the theory of wearing-out put forth by some has assuredly an antidote which the Chinese have been far-seeing enough to take hold of. Other countries afford examples in like manner of long-continued cultivation being still attended with a useful result, when prudence and industry direct the operations of the cultivator. But a reverse state of things is common in many countries that once by their civilisation and standing held a proud place in the history of the world. The hilly region of the Holy Land is, unquestionably, less fruitful now than it was three thousand years ago; and it is likely some of the fairest provinces of Italy are in like manner deteriorated by a long course of mismanagement. Other instances might be given; but enough has been said to prove that, in the temperate and colder districts of the earth, a great amount of skill and industry is required to maintain that healthy fertility of the ground so necessary to the well-being of the crops required for the sustenance of man. Let us now take a glance at what has been done at home to attain this object, and then notice some of the substances occasionally met with as agents in increasing that productiveness, or, in other words, what are commonly called fertilisers.

In the above introductory matter I have pointed out the

necessity, when more than ordinary productiveness is wanted, of resorting to some means in addition to those which nature has provided; and this assistance is more necessary in a climate less favourable to vegetation than those of the tropics. However, enterprising cultivators have not been wanting, and in this country the results of numerous and carefully-performed experiments in husbandry and gardening have from time to time been placed before us. Discussions have also verified what is safe and right to follow, and certain substances have been so generally acknowledged to be favourable to the growth of particular plants as to be almost household words. Some manures, too, which have been put forward with high-sounding names have failed to produce such good results as were expected of them, and have consequently fallen into disuse, while they in turn have been succeeded by others sharing a similar fate, but not without having an occasional supporter who would state his conviction of their utility. My object, however, is not to go through the list of manurial substances that have at various times been urged on the attention of the farmer and gardener, but merely to point out some of those within the reach of the latter, which are not so extensively used as they ought to be. I may also make a few stray notes on those so strongly recommended of late years, and which have either not realised the expectations formed of them, or could not be had in sufficient abundance.

CHARCOAL.—Some twenty or more years ago no little stir was made in the gardening world, by the marvellous effects which this substance was said to have on vegetation. Charcoal in lumps or charcoal dust was reported to possess some peculiar virtue of great importance to vegetation, and a number of cases were recorded in which it was said to have been used with such success that it promised to equal in importance gas, steam, and the other improvements of the age. That its utility as a fertiliser in conjunction with other substances is very great there cannot be a question; but it gradually sunk in estimation, and eventually took its place with other things of like merit. Nevertheless, it must be admitted, that while it was at the height of its popularity, many persons seemed to look down with contemptuous disdain on the plodding dung-cart. Charcoal was said to be capable of imparting an almost marvellous vigour to many plants on which it was tried—Cucumbers, Pines, flowering plants of various kinds, and even out-door crops. Nay, so far was the charcoal mania carried, that a gentleman who had extensive plantations in the West Indies, prepared a large quantity on his estates in England, and sent it over to Demerara to dress his sugar plantations with. Of the result of this latter experiment I never heard, but the gradual decline of this article to its place with other manures, and the subsequent depreciation of West Indian property from political causes, naturally led to the abandonment of all previously concerted plans for exporting charcoal. Nevertheless, it continued to be popular with some, and its merits are acknowledged at the present day.

In potting plants of various kinds, its use in a rough state as drainage has been at all times a favourite practice and still continues to be so, and in this way few plants object to it, while a large number seem to enjoy it much. Small pieces of charcoal mixed with the soil, when plants require it to be very open, are also beneficial, and many Orchids and other plants of delicate habits seem to enjoy the open texture which a quantity of charcoal or its dust gives to the mixture they are grown in. Charcoal dust or ashes have been from time immemorial recommended for Onions; and mixed with the soil in which young Cabbage and other plants of a similar nature are sown, it is said to prevent the clubbing which would otherwise happen. Some other qualities it also has, but they must not be gone into here; suffice it to say that charcoal, unlike ordinary decaying manures, which impart richness to the mould they are in contact with, appears to act by absorbing liquids at such times as they are supplied, and parting with them to the roots of plants as they are wanted. Charcoal, though certainly not a barren substance, is nevertheless far from being agreeable to vegetation when alone, but when mixed with other ingredients, as good soil &c., its presence adds materially to the value of the compound. Decaying but slowly, and at the same time being a good absorbent, it takes up moisture from the adjoining soil, and parts with this to

the roots of the plant, which cling round it for the purpose of taking it up. Its limited supply will always prevent its being used to any great extent for out-door or field work; but for special purposes, where it has been tried, it appears to have given every satisfaction, not as a stimulant, like many manures, but as an enduring item in the compound, to which it might not be improper to apply the term "storekeeper," as its duties seem to be to look out for liquids, and lay in a supply, which it deals out to its customers as wanted.

BURNT CLAY OR BRICKDUST.—This substance fell far short of the popularity of the last-named, although it was brought forward soon afterwards as a sort of rival, as reports circulated in its favour made it appear quite as valuable. Subsequent experience, however, has proved this not to be the case; although as an ingredient in a mixture it is not without its merits. It must, however, be regarded as having failed in one of the principal objects for which it was specially put forth—namely, as a substance in which cuttings of delicate plants or those difficult to propagate were likely to root well. On the contrary, it is inferior in this respect to both sand and charcoal-dust. Burnt clay, however, has the advantage of often being procurable in larger quantities than burnt wood, and on that account it is used more extensively for out-door crops. The refuse of a brickyard or the charred red ashes of clay that have been burnt for the purpose are both excellent substances to work into stiff clayey lands to diminish their adhesiveness, and for this purpose they may be used freely. The mode of burning clay having been explained several times in this Journal it need not be repeated here. As an ingredient in mixtures for potted plants it merely acts as drainage when in a rough state, and in this capacity it is inferior to charcoal.

PEAT.—The acknowledged utility of this requires no comment further than to say, that useful as it is now considered to be, it has in some degree fallen into disrepute during the last eighteen years, or rather that it has not attained that estimation which it was previously expected to do. The remarkable instance of good Pine-growing in France, which was said to be entirely owing to peat being used, created no little stir amongst those who regarded their own especial mixtures as the very best that could be had. From Pines it was easy and natural to try it on other things, and Cucumbers were next successfully experimented on. Grapes, I believe, were tried, but I am not aware of anything particular worthy of note resulting from the trial, and I think the experiments were not repeated. Its applicability to Pines and Cucumbers was held to be established, and it was used by some growers for a few years in their Cucumber-frames. However, I believe it is now only very sparingly employed in that way; while, on the contrary, it is more extensively used than ever on the potting-bench, the number of plants grown almost entirely in it being very great, and for a considerable number it also constitutes a component part of the soil along with leaf mould, maiden earth, &c. In fact, the utility of peat requires no encomium here. What, however, is much wanted is some easily available test by which its properties may be known, without running that risk of doing harm which is sometimes the case when peat of a deleterious nature is used, and there are some kinds which deserve that name by their action on plants. The peat found in places where it has been formed at some early period by the action of water on the substances composing it, differs very widely indeed in its properties as regards plants. Some of the peat so obtained is suited to the wants of only a very limited number of plants, and is poison or little better to the majority of the plants that are more especially the ornaments of the plant-house, the shrubbery, and the flower-border.

I have more than once known fine large Rhododendrons very severely injured by a pernicious kind of boggy peat having been applied to the roots. Not long ago my attention was called to the state of some young plants that had been planted in a soil not by any means suited to the Rhododendron; but to assist it and give the plants a start, about a barrowload of a mixture consisting of bog peat, leaf mould, sand, old sawdust, and woody refuse was added, and it was expected that this compound would start the young Rhododendrons, and that by degrees they would, perhaps, take to the ordinary soil of the bed. Many of the plants, however, never made a root in the mixture, but dwindled away after

the ball which accompanied them was no longer able to maintain them; but some made an effort and succeeded in penetrating with their roots into the ordinary soil of the bed, and thereby succeeded in evading the food that had been provided for them to their dislike. Many other remarkable things might be said of peat, but as an article may possibly appear on this subject at another time, it is needless pursuing the subject further than to affirm peat to be one of the most useful substances known to the gardener.

J. ROBSON.

(To be continued.)

PRUNING VINES.

I HAVE lately come into possession of a vinery which has been erected about fifteen years, containing four Black Hamburgs and two White Grapes. The Black do well, but the White do not. I think they require a different treatment from the Black. What should I do with the White Grapes to make them do well along with the Black? The Black have always borne and ripened a good quantity of fruit. The roots are outside the house, and enter through holes in the wall about 2 feet below the surface, and run 2 feet below the surface of the earth outside, which is very heavy. Should it be dug and manured or not? The leaves have all fallen, and the wood is well ripened. When and how should the pruning be performed?—N. M. D.

[It would relieve those to whom falls the answering of such questions as that of our correspondent relative to the White Grapes from a good deal of guess work and unnecessary "it's" and "and's," if the names of varieties were given as well as other particulars regarding them. White Grapes is a wide term, comprehending distinct varieties of Grapes, which require very different treatment in some points upon which success or failure often depends: consequently we are obliged to approach such questions by a series of uncertain zigzag parallels, instead of replying in a definite and straightforward manner.

If the White Grapes which have failed where Hamburgs have apparently done so well are Muscats, it is possible that the failure may have been caused by too low and moist a temperature when in bloom, which prevents the pollen from getting dry and taking effect. Or, presuming that they are Muscats, the Vines may have been late in being started; in fact, allowed to break late of their own accord, as is often the case where there is only one vinery. The Muscats may not be thoroughly ripened in autumn, requiring, as they do, more fire heat than Hamburgs. This, in conjunction with a moist low temperature when in bloom, may have caused the failure, presuming that they have shown fruit plentifully enough for a crop. To remedy these evils the Muscats should, in a mixed vinery, be always at the hot end of the house, if there be a difference, as there is in most cases; and when in bloom the atmosphere should be dry, with a temperature of at least 70° till they are set.

The other White Grapes which were generally planted in cool vineries fifteen years ago, such as Muscadines, Sweetwaters, and one or two more, should not fail where Hamburgs succeed. True, the old Sweetwater is a precarious setter, and should be kept dry, the same as recommended for Muscats when in bloom. On the other hand, if the Vines have failed to show sufficient fruit for a crop, then the fault, if Muscats, has most likely arisen from improperly-ripened wood, and more fire heat must be applied in autumn to ripen the wood more perfectly. Muscats, however, should never be planted in cool vineries; and if our correspondent's White Grapes are Muscats it will be best to inarch them with Muscadines and Sweetwaters, if not convenient to apply more heat to make the wood hard and brown before the leaves are shed. We hope these remarks will meet the case; if not, we will be happy to hear again from our correspondent with fuller details as to sorts, &c.

The great depth of bad soil over the roots is also calculated to retard the proper ripening of the wood if the variety is a Muscat. Roots of Vines at such a depth in uncongenial soil do not perform their work so well as when nearer the surface. In order to bring the roots nearer the surface, the inert soil should be taken away down to the roots, and covered 8 or 9 inches deep, with a compost made up of

two parts turfy loam well chopped, one part mortar rubbish, and one part rotten dung. This will induce the roots to come to the surface, especially if otherwise treated, as detailed in recent Numbers under the head of "Lifting the Roots of Vines, &c," and to which we refer our correspondent, instead of needlessly repeating the matter again.

The digging and manuring of such a depth of bad soil over the roots would only tend to increase the evil, for heavy putty-like soil is only made more unsuitable for Vine roots by its being manured. Were it simply light poor soil, then the addition of some good manure might entice the roots upwards; but not so thoroughly as the method to which reference has been made.

With regard to the pruning, it is one of the most difficult matters to answer in a way that will be certain to meet your case, for Vines in various conditions must be variously pruned to make sure of a crop. In the case of well-ripened Vines we cut right back to the first bud at the base of last year's growth; and most varieties bear well by such a system of pruning, and none better than Muscat of Alexandria. But such close-cutting work is the best way only when Vines are well ripened and strong; and in the case of Vines ripened late with a little application of fire heat it is not to be recommended. In the latter condition it is much safer to leave two eyes, or even to cut at the third eye if it be the most plump and ripened. There is nothing gained by leaving more than three eyes. If the third eye, from which a well-developed leaf has been matured will not yield fruit, then there are none further out from the main stem likely to do so. In fact, the wood at a few eyes further from the base is generally more pithy and less fruitful than at the third bud, for the ripening process begins at the base and progresses to the extremity of the shoot, which is sometimes green when the base is hard and brown. If your Vines are not thoroughly ripened, the best way for you to pursue will be to leave two or three eyes; or to cut wherever there are the roundest buds, and the hardest wood with

the least pith, pruning at the first eye, A, for well-ripened Vines; at the second and third eyes, B and C, whichever of the two is most prominent and hard, for indifferently-ripened Vines or those which are weakly.—D. THOMSON.]

NOTES FROM CUMBERLAND.

I RECENTLY read with much pleasure in your Journal a very instructive account of the Pampas Grass.

Two or three seasons ago I bought two packets of seed.

Those from Mr. Thompson, of Ipswich, I believe all grew; but I was much bothered in weeding them, as, never having seen them in their young state, I could not tell which was "twitch"—i. e., couch grass, and, probably, threw hundreds away. However, I raised to a good size seventy or eighty nice plants. I gave a great number away to persons in various parts of the county, and I do not know what became of the plants. The remainder I planted out and had very bad fortune. Two extremely hard winters set in, which made a clean sweep of nearly everything; and the geese ate the survivors when they were beginning to sprout and do well. The avidity with which the geese looked for them was most remarkable. No matter in whatever secure and secluded nook in the grounds they were planted the geese found them out, as a hare or rabbit does a Pink or bit of Parsley. I kept one plant in a pot in the greenhouse for the first winter, and it is now a splendid object and in fine bloom. I have no doubt that it would have bloomed in a great mass if it had not been for two nights of severe frost in the early part of October. We have also had a dreadful autumn: incessant rain ever since the beginning of September. My plant is in the centre of an "American" bed, and, being close to the wash-house window, receives plenty of soap-suds and greasy water. I find it a perfect glutton in this respect, and that it cannot be overdosed with rich liquid stuff. May I ask if your correspondents find them evergreen, or only so in mild winters like many other things? Mine never suffered last winter, nor up to this time, and I live in a cold locality, two miles from the north side of Skiddaw.

At the time that I sowed the Pampas Grass I also tried a packet of Erianthus Ravenne, which is described as hardier and better in every way. None of my seed came up, and Mr. Thompson informed me that none of his did. I have never seen a plant of it, but it is still puffed and recommended every season. Have any of your correspondents tried it? I also much wish to know if the Pampas Grass ripens seed in England or not?

I am now coming to the main point of my letter. Why is the seed of it so dear, and small plants a shilling each? One spike would contain seeds enough to plant at least half an acre, if not far more.

That it is the finest introduction in its line that we ever knew there cannot be the slightest doubt. If, as we are given to understand, the Pampas Grass covers large plains in South America, or wherever it comes from, could not the seed be imported in large quantities also? Why should it cost a hundred, or, perhaps, a thousand times as much as the seed of cultivated grain, birdseed, &c.? I am firmly of opinion that it might become one of the permanent features of the country, and I do not think the seedsmen are dealing fairly with us by keeping up the present price. Standing permanently a few yards apart it would be a splendid cover for game, and the leaves being very juicy and sweet would be good food for hares in the winter season. If protected till two or three years old no amount of hares would injure the plants.

If, again, the seed were sold at a moderate price, a couple of acres of it on a mountain would be invaluable as a refuge for sheep as well as game in deep snows—certainly much better than the tops of stunted heather, which is all they can procure at certain times. Of course, I would plant it in a snug sheltered place, and protect it till three or four years old—I mean prevent its being eaten. For our mountain sheep it would do splendidly, as they could burrow in it like rabbits, and would have this great advantage, that it would not tear the wool of them, which is the great objection to patches of Hazel, Sloe, Thorn, or Gorse. The number of sheep that lose their lives in this part in a severe winter by being hung in briars, where they go for shelter, is incredible. I suppose I am justified in assuming that it is perfectly hardy under favourable circumstances.

I have often urged and suggested to the Acclimatisation Society the advisability of looking out for hardy shrubs and grasses, affording at the same time food and shelter for game. The British Isles are very badly off in this respect. I have written, along with other gentlemen and naturalists who saw this great want, several letters on this subject to the paper which has hitherto been the organ and exponent of the Acclimatisation Society. This Journal, however,

having lately discarded in a great measure its correspondence on natural history, and taken to other subjects, we are at a loss to know how to communicate our wants and information to each other.

What sort of thing is the "Elephant Grass" that the Acclimatisation Society state they have received seeds of? Do any of your readers know anything of its habitat or peculiarities? I could obtain some if it were worth while or if I knew how to treat it.

Amongst other things I may mention that I have a great number of the Tritoma. In the last fine summer we had, I saw some seed advertised in your columns as having ripened about Kingston-on-Thames. I procured a packet, and I believe every seed grew. I have a great number now coming into bloom daily in the open air in December. They seem quite hardy, and some of them are quite different from any I have seen in nursery gardens. Many of the florists about here have lost all their stock long ago. I do not know what to do with mine, as to be in full luxuriance now seems so unnatural, and I am afraid of the effects of frost. If I had had a large greenhouse or orchard-house like some people, I should have had an avenue of them. How well they would have looked along with the Agapanthus, which is now in full bloom.

Allow me to deplore the death of Mr. Beaton. Having been a subscriber to your work from the first, I have always read his shrewd and practical remarks with the greatest avidity and pleasure. His death is an irreparable loss to the experimental part of floriculture. I think he was wrong about the pronunciation of Gladiolus. I ought to be somewhat of a classic, and, taking it from its root, *gladius*, it decidedly ought to be pronounced "Gladdy-o'-Luss," like an Irishman's name, softened somewhat for the sake of euphony. —JACKSON GILLBANKS, Whitefield, Cumberland.

RENEWING AND PLANTING A VINE-BORDER.

I AM about to renew my Vine-border, and I intend to plant the Vines inside, so that the roots can pass through arches to the outside border; but I find the crown of the arches is nearly 2 feet lower than the top of the outside border. Shall I have to lower the border? or will it injure the roots by being so deep, as I intend placing the greater portion of the roots as far through to the outside border as I possibly can when I plant the Vines? Also, there is a slate tank, about 6 feet from the front wall, sunk in the inside border level with the surface. Will that injure the roots passing round and near it, as I intend the house it is in to be my early house to start about Christmas, after two or three years? What sorts would you suggest my planting? I shall have room for seven Vines in each house; one house to come on with but little artificial heat.—AN OXONIAN.

[The arches of your vinery front are much too low; and to allow the roots to pass out under such a depth of soil would be very undesirable, and could not fail to act against the success of your Vines, more particularly if your subsoil is cold, and the border only on a level with the surrounding surface. It will therefore be necessary to have the soil not more than 9 or 10 inches above the crown of the arches—in fact we prefer, when it can be done, to have the crown of the arch not more than 6 inches below the surface of the soil. The roots are sure to go out deep enough. Now, if the surface of your border requires to be 2 feet above the arches in order to bring it to the level of the surrounding ground, to have it at the depth in relation to the arches that we have recommended would throw your border considerably below the natural level, which would not only be injurious but very unsightly. Granting that such would be the case, we would recommend that the arches be built up altogether with brick or stone, and that holes be cut in the front wall above the bricks which form the arch. This would not in the least weaken the front of your vinery; and it would let the roots out at the depth of, say, 9 or 10 inches below the surface of the soil. And this is not all that would be gained by such an arrangement: it would prevent the roots from going out deep, which is always desirable, as the tendency of roots is almost always downwards to too great a depth before they take possession of outside borders. We adopted

this plan with two vineries two years ago, and find that it has answered admirably, and saved the reconstruction of the whole front wall.

For your early house it would be a good plan to build up your arches, and not make openings above them till the Vines had made a season's growth in the inside border. We did so with one of the vineries referred to, and find nearly all the roots inside after the Vines have been planted two years. They are just now finding their way into an outside border made the following year, when the openings were made higher up. We do not approve of your placing the greater portion of your young Vine roots in the outside border at planting time. This should just be reversed, because young Vines planted inside the front wall and having the run of both borders always send the great majority of their roots into the outside border, and for forcing this is not desirable, unless bottom heat and protection can be applied to the outside. You should, therefore, whatever you do about confining them to the inside for a year, lay most of the roots towards the inside border.

The slate tank will do no material harm unless it leak. Whatever you do about the arrangement we have recommended, see that your border is well drained, and so that no water can stand about the roots. The materials considered best for its formation you will learn about by referring to back Numbers of this Journal.

For your early house you cannot do better than plant four Black Hamburgs, one Buckland Sweetwater, one Muscat Hâtif de Saumur, and one Bowood Muscat. For your second house—three Black Hamburgs, one Lady Downes', one Raisin de Calabre, one Burchard's Prince, and one Muscat. The two last-named, particularly the Muscat, should be planted at the hottest end of the house, and the Hamburgs at the coolest, and by such an arrangement you will find that a long succession of Grapes will be afforded. Burchard's Prince and the Muscat will require more fire heat than the others to ripen them well.—D. T.]

ORCHARD-HOUSES AND PEACH-HOUSES.

In a communication by "T. R." on "Orchard-houses and Peach-houses," the writer says, "Six full-sized Peaches are as many as can be grown on a square foot, either of trellis or wall." Now, if that is not a mistake either of the writer or printer, I think six are far too many to grow on a square foot, and that calculation might mislead some; for even practical gardeners sometimes err on the score of over-cropping. Mr. McEwen says in his "Culture of the Peach and Nectarine," page 10, "You will see what I mean by a heavy crop, when I state that on 450 superficial feet covered with wood, I gathered forty-nine dozen of Peaches, many of which weighed over 8 ozs., and very few under 6 ozs." This was good work; and I feel convinced that the trees could not have done it without very liberal help. This calculation is not much more than one Peach to the square foot; and the question is, Will a Peach tree support more than that of full-sized, well-flavoured fruit for a number of years in succession?—T. L.

[Sometime the last autumn I observed in a contemporary that twelve Peaches might be allowed to a square foot of trellis. I thought this extraordinary, and consulted Loudon, Thompson's "Gardener's Assistant," and McIntosh; in none of them could I find the question gone into, and so I in my practical way made a square foot of four pieces of lath, and placed it on a wall to which a Peach tree bearing a full crop of fair-sized fruit was trained. I then found that my square took in six Peaches, leaving them plenty of room; they were not very large, but measured from 7 to 8 inches in circumference. I thence concluded that that number could be reckoned as a full complement for a healthy Peach tree on a wall or trellis; but at the same time I felt that such a regular crop must be of rare occurrence, and I feel I ought to have so expressed it. A square foot, as every boy knows, contains 144 square inches, six fruit to a square foot would thus give to each 24 inches. This seems a large space on paper; the diameter of a medium-sized Peach may be taken at $2\frac{1}{2}$ inches, so that if a Peach tree would be always healthy and kind in bearing, six good fruit may be grown on a square foot of wall or trellis; but I must confess that in measuring

off a square foot of my Peach trees I thought only about testing the assertion I had seen in print, and not the future of the tree. One Peach to a square foot, or 144 inches to one fruit, seems but a scanty crop on paper; yet if we could see a Peach tree on a wall occupying 200 square feet—that is, on a wall 10 feet in height, filling up a space 20 feet in length, a rare occurrence, two hundred Peaches would be reckoned a fine crop. A gentleman, who amuses himself by growing Peaches for market, informs me that he allows two Peaches to the square foot; for, he says, "Unless they are grown to the weight of 8 or 9 ozs. they do not make the top price, the public at the present day looking so much to the size of fruit." This may be taken as an extreme case, and I should think three Peaches to the square foot may be reckoned as a safe crop, giving large fruit, and not injuring the future of the tree. Amateur Peach-growers may for the future carry out the thinning of their wall or trellis Peaches to a nicety by merely placing a frame of 1 foot in diameter against their tree while thinning the fruit, and thus easily regulate the crop of a large space by measuring off 1 square foot. It is strange that our writers on gardening have not given directions on this head, so far as I am aware; neither have I seen in your columns the question agitated. We have, therefore, to thank "T. L." for his pertinent inquiry.—T. R.]

MR. W. WOOD, OF MARESFIELD.

THE present year has taken away from amongst us many who have made a name in horticulture, and who, both in public and private, have been worthy members of a fraternity that numbers as high-minded and honourable men as are to be found in any calling. Amongst those whom we may call the founders of English horticulture the names of Veitch, Low, and Wood hold a high position; and the head of each of these firms has been taken away during this year, Mr. Wood, of Maresfield, the last of the three having died on the 3rd inst. at the advanced age of 82. In early life Mr. Wood had been engaged in a portion of the public service where qualities of no common order were required, and had seen much of continental life, and that, too, in the best aspects of it. This gave to his conversation (I am told by those who knew him well), a great charm. He had a large fund of anecdotes, and told them with great vivacity and earnestness. At the close of the war he settled at Maresfield, commenced Rose-growing in a small way, gradually increased his business, until in those days, when Rose-growers were fewer than they are now, he used to be found competing, and that successfully, at the great exhibitions of the day. During the past few years declining strength has hindered him from taking that active part in his business which he formerly did; but he has found a worthy successor in his son, Mr. Charles Wood. In his private character Mr. Wood was highly esteemed by all who knew him. He was a kind and indulgent master, and I have heard his old servants speak of him in terms of great affection and esteem. As one looks at the character of those men who have now gone from amongst us, and remembers the high position they held, we can only hope that those who bear their names and hold the positions they won for them, may as worthily fill their places; and I am quite sure that such will be the case with Mr. Wood, of Maresfield, whose son, Mr. Charles Wood, is well known as much for his business habits as for his urbanity and kindness.—D., *Deaf*.

CUTTING OFF THE LEAVES OF STRAWBERRIES.

[We have received another communication from Mr. Quintin Read on this subject, giving quotations to prove that the leaves of plants are at once their lungs and stomach. These we consider needless, for it is a long-acknowledged fact. More strengthening to the advisability of his practice is the following, which forms the conclusion of Mr. Read's letter.]

"I might multiply irrefragable testimonies, but forbear lest I should be considered prolix; and will, therefore, con-

clude these remarks by quoting an observation made by the late Mr. Errington, the respected gardener to Sir Philip Egerton, Bart., of Oulton Park, Cheshire, when writing on the subject of Strawberry-growing, and alluding to the cutting off of the Strawberry leaves a short time after the crop is gathered.

"In an article contributed by him to your Journal, Vol. XVI., August 1856, your correspondent will find the following *upropos* remarks:—"Here let me advert," says he, "to the management of the foliage, on which a good deal depends. The old practice of mowing off the leaves soon after the crop was gathered is now universally repudiated, and most justly. It classes well with the barbarous practice, once recognised, of cutting down all the Asparagus possible, in order to strengthen the roots. These conceits, thanks to the gardening press, are gone by, surely for ever."

"These remarks emanating from one of gardening authority, whose energy and skill in his profession none can gainsay, must certainly have some weight with 'J. B. C. P.,' unless he is so wedded to his own 'barbarous system,' that nothing will induce him to adopt a milder and more careful treatment of a plant producing one of our most delicious fruits.—QUINTIN READ, *Biddulph*."

[Here let the controversy close. Strawberries may be grown according to the scythe system, but very few will adopt it.—Eds. J. of H.]

MUSHROOM SPAWN.

In glancing down the advertising columns of your valuable Journal a short time since, my attention was attracted by an advertisement—"How to Grow Mushrooms all the Year round without buying Spawn;" and, thinking it might be something worthy of attention, I procured the instructions, but was much surprised when I received them. They go on to say, "In a very dry place, with well-prepared droppings or short dung, I make up a bed just as if I were going to grow Mushrooms;" then they say, "This I spawn well." Now the advertisement says, "without buying spawn," but one must have spawn in the first place to spawn that bed with; and I think if a bed is to be spawned at all, why not spawn the Mushroom-beds at once and save the time and trouble of spawning the first-named bed, which will probably take, say, six weeks at least? I know you are ever anxious for fair play on all sides: I think for the benefit of your readers it should be expunged from your advertising columns "as a gross imposition."—A JOURNEYMAN IN THE NORTH OF IRELAND.

[You are not the only one who complains of the imposition; and so soon as we learned the truth, we directed that no more advertisements from the same party were to appear in our columns.]

PROPAGATING CENTAUREAS.

DIRECTIONS for propagating the Centaureas have lately appeared in your columns, and March is pointed out as the proper time. A month ago, having to trim a candidissima, I cut up the shoots into bits from 1 to 6 inches long, leaving each with a joint, and all these have struck in the pots they were placed in, half a dozen in each pot. They had the advantage of about 60° of heat; but some pieces which were stuck in the open ground at the same time seem also to have taken. Perhaps this may interest some who wish to gain time.—WELLSKNOWN.

[The Centaureas may be propagated in autumn, but, then, be it remembered that the young plants have to be wintered.]

CHINA GRASS AND JAPAN FLAX FOR TYING.

I HAVE received this morning, from Mr. Allison, 22, Lawrence Pountney Lane, some samples by post of four sorts of material for tying, three of which, from their fineness and toughness, would, no doubt, answer for fine tying, whilst a coarser sort might do for rougher purposes. We can form, however, no idea as to their economy, as the price of none,

per pound or otherwise, is stated. The utility for tying will much depend on the price. Cuba bast when good is a capital material for tying, but it is more expensive than the finest Russian mat. If we could procure bundles of the soft finest bark, of which part of the Russian mat is composed, without being woven at all, we might obtain fine ties at an economical price. When cut from mats there is ever double waste. These samples of Mr. Allison are tougher, and may be split into much smaller threads than Cuba bast, whilst they are almost as soft as the softest and most silky matting; and if the price should be moderate we would have no doubt of their usefulness. Mats are so dear and littery for this purpose, that for much of the flower-garden work we have for years used balls of fine thread, believing them to be neater and more economical.—R. F.

AMMONIATED OXIDE OF IRON AS A MANURE.

I HAVE just received your little work on ammoniacal liquor produced at the gasworks, which I consider very interesting, and can bear testimony to its fertilising properties. Perhaps you would give me your opinion respecting the oxide of iron used by some of the gas companies to purify the gas. It contains a large per-centage of ammonia. I tried some of it upon grass last year: it turned the grass quite white, no doubt because used too strong. I made the inquiry from the Editor of the *Gardeners' Chronicle*, as I take both papers, but he appears unable to answer the question; but as it seems to be one you have studied, you will, doubtless, be able to enlighten me. The annexed is an analysis:—

Water	22.60
Organic matter	40.30
Oxide and sulphide of iron	21.50
Sand	5.40
Sulphate and carbonate of ammonia	11.20

—A SUBSCRIBER, *Liverpool*.

100.00

[There is no doubt that this ammoniated oxide of iron is valuable as a manure. We have used it on a small scale, first combining the iron as well as the ammonia with sulphuric acid, thus converting both into sulphates, each of which is well known as a fertiliser. The quantity of sulphuric acid required must vary according to circumstances, but no harm would occur to the crops even if all the oxide was not converted into sulphate of iron. Three or four hundredweight of the sulphated compound thus formed mixed with twice its weight of ashes, and sown by hand in early spring, would be a good top-dressing for grass. We used three times that quantity with good effect dug into the soil at the time of planting Potatoes.]

THE GARDENERS' YEAR-BOOK, ALMANACK, AND DIRECTORY, 1864.

By Robert Hogg, LL.D., F.L.S., &c.

THIS is the fifth issue of this valuable manual, and much the best, though its predecessors were very good. For many purposes, and especially for reference, the first issue for 1860 is almost as valuable as the present for 1864. With the exception of the main feature of a directory, which can only be altered and enlarged to meet changed circumstances, there is a great variety of matter, and sometimes a continuation of the same subject from one year to another. For instance: in 1860 and 1861 there was a very full calendar of gardening operations, but this calendar was omitted in 1862 and 1863. In the four preceding years the space in the middle of the page for the almanack of the months was chiefly devoted to facts in natural history, such as the arrival of birds and the flowering and foliation of plants. This season these twelve spaces have been devoted to a kitchen-garden calendar; and next year the same space is to be given to a flower-garden calendar, to be followed by a fruit calendar. Again: in 1863 there is a nice chapter, with a number of engravings, on the seeds of plants; and in the present issue there is a chapter in continuation on the germination of seeds.

Besides the usual materials of an almanack as to taxation, the Post-office regulations, and British monies, weights, and

* Equal to 3.75 per cent. of ammonia.

measures, there are useful tables as to foreign monies, weights, &c., as respects France, Belgium, and Prussia. The other novelties are—a chapter on absorption, a very valuable article on aphides, a valuable summary of the meteorology of the months, and an essay on and a description of the new Roses of 1862 and 1863, as proved by Mr. William Paul, the descriptions being of great value to the Rose-grower. Besides such matters, the two great features of the work have hitherto been a descriptive list of the new vegetables, fruits, and flowers of the past season, and a trade directory of all the nurserymen, seedsmen, and florists, so far as known in England, Scotland, Ireland, and the Channel Islands, and the principal firms on the continent, and in previous issues all the principal nurserymen in America. To this has been added this season a new feature, worth far more than the price, i.e., charged for the little book. It consists in a list, extending to some twenty-two pages, of the designations of some of “the most important of the seats of the nobility and gentry in Great Britain and Ireland, the names of the owners, their gardeners, and the post towns near which they are situated.” No doubt this list will be rendered more full, complete, and free from mistakes every year, and will fill up a want long felt. Many a time when we would have liked to have visited a place have we been deterred from failing to discover how we were to reach it, or how we could gain access by a letter to the gardener. There will be no difficulty as to writing now, as the post town and the county are given. At first sight we thought the railway station and the distance in miles would have been better than the post town, which is often a long way from the place; but on further consideration we think the post town is the best, as for 2d. for a letter and an answer all the necessary information may be obtained. The mere distance from a station is a matter of great importance to the visiting gardener, unless there be a party to share the expense. Not so long ago, when rather tired, we were asked for more money to take us two miles, wait an hour, and bring us back again, than we have paid for a jaunting-car for a day in Ireland, and making the driver a pleasing companion by giving him something extra for himself into the bargain. All who go from home once or twice a-year, and wish to see something fresh will hail this list as a boon.

The new plants of the year and where figured, described or exhibited are fully given; and long lists and descriptions of florists' flowers with the awards they have respectively taken, occupy nearly twenty closely-printed pages, and must be of great value to enthusiastic amateurs. The descriptions of new and notable fruits occupy five pages, and to these we refer our readers.—F.

RONDELETIA SPECIOSA CULTURE.

In answer to an inquiry from “G. E.,” it is a stove plant, and one of the handsomest in cultivation for exhibition or decorative purposes. *R. speciosa* major, a variety having a more vigorous habit and finer foliage and bloom, is the most desirable kind. You leave us in the dark as to the time of exhibition and the present size of the plant. Supposing, however, that it is strong and in good health, you will pot it in March, giving a good shift, draining well, and using a compost of sandy fibry peat one-half, loam from rotted turves one-fourth, leaf soil, pieces of charcoal the size of walnuts, and silver sand in equal parts the remaining fourth. The whole should be well incorporated, and be in a moderately dry state previous to its being used for potting. The roots should have as much of the old soil taken away from them as can be done without destroying the fibres. Place in the stove, and syringe overhead frequently, but keep rather dry at the root until growth fairly commences; then water more freely, but still allow the soil to become dry before water is applied.

A moist atmosphere should be preserved until the plant has made considerable growth—say shoots 9 inches long (which should not be stopped, for the blooms come from the ends of the shoots), then keep rather drier, and let the plant have all the light possible in every stage of its growth, but more at this period of the plant's growth than at any other time. When the trusses begin to open, a little weak manure water applied twice a-week will materially increase

the size of the blooms, and an occasional syringing is advantageous. Towards the time when the flowers expand more water should be given, and abundance when the plant is in bloom. It is usually trained round sticks so as to give it the appearance of a globe, and this is not an undesirable method. A temperature of 55° to 65° suits it in winter, and 65° by night and 75° by day when growing, with abundant ventilation on all favourable opportunities. Plants treated in the above way usually flower in July and August.

It may be necessary to retard or keep the plant back, and this can be done by keeping it cool; or to force it into bloom in order to have it in flower at the right time, the weakest and straggling shoots should be removed now, so as to admit light to the stems, light being the agent by which it is caused to bloom profusely: therefore, the shoots should not be tied one upon the other, but light must be admitted to all parts of the plant alike, or it will become lopsided or an ugly specimen.

CROCUS IMPERATONIUS.

YOUR correspondent will find this lovely Italian less tender than might be imagined. It will thrive and increase out of doors if carefully grown in a warm corner in pure sandy loam, and lifted every year, to be replanted after being kept for a week or two in a pot of dry earth to ripen the bulbs.

Although starting early, its flowering out of doors is prolonged on into the milder weather, and it may be often seen blooming in company with the earlier garden Crocuses. I grow it myself in a special sandy bed made up like a florist's Carnation-bed. If the weather is harsh I protect by a glass light, supported on four posts at the corners. This is especially necessary for the autumnal sorts, the blossoms of which suffer more from the wind and cold rains of autumn than *Imperatoni* does from our rude early English spring.

It is useless to attempt the cultivation of the genus in pots. The Dean of Manchester, however, kept his marvellous collection of them principally in pots plunged in a bed of sand. Had your correspondent mentioned his case earlier I should have had pleasure in sending him good bulbs. I obtained my bulbs from the hill above Terracina.—C.

CATTLE AMONG YEW.

As you ask for information with respect to the poisonous qualities of the Yew tree, there is no doubt in my mind that, under certain circumstances, there is danger; but my own cattle have never yet suffered. I attribute this fact to their having plenty of other food. In one small field near my house there are nine Yew trees of about thirty-eight years' growth. In another field there are five of the same age. Into these fields I always have turned my milking cows in the early spring and at other times. My young cattle also go there. My horses and sheep have accompanied them, and I never have had any accident.

My neighbour some few years since lost several heifers which had broken through the fences, from eating Yew in a plantation; but their pasture was a very poor one. If cattle are driven by hunger to eat Yew, and probably the same may be said of many other sorts of evergreens, it will kill them.—P.

[Our correspondent is a clergyman, and, from this statement, certainly one of the most venturesome in the Clergy List.]

DWARF GROWTH OF LAURELS UNDER LARGE ELM TREES.

THERE are various situations where it is almost impossible for any kind of shrub to thrive, and, as an instance, the situation above alluded to has frequently been planted, and always without success, with various kinds of evergreens.

The border that I now allude to faces due south, and is backed by a wall about 10 feet high, which is very neatly covered with Ivy from the bottom to the top. In spite of

the huge limbs and branches from the large Elms that over-shade it, the Ivy succeeds very well. About four years ago it was determined that nothing more in the way of large plants should be placed in this border, to be subjected to the shade and drip that the other evergreens had previously suffered from. The border was cleared of all its half-perished plants. It then received a liberal supply of manure, which was trenched-in to the depth of 2 feet, and during the process of trenching care was taken that every root from the old plants was extracted. A portion of the border was then planted very thickly with common Laurels, from 18 inches to 2 feet in height, the largest plants being placed at the back, while the smallest came to the front. Thus a gradual slope from the back to the front is maintained. They have been cut back each year to the desired height, which is 2 feet at the back, and 18 inches in front. By so doing they have broken very thickly and regularly, nearly every particle of ground being covered. The beautiful appearance they present is so much admired by every one that has seen them, that we have been induced to plant more extensively this autumn.

I have seen the Periwinkle and Ivy succeed very well as a more prostrate growth, but the Laurels are by far the neatest when attended to, and in every way superior to the abovenamed.—J. B. C. P.

CELERY IN COCOA-NUT FIBRE REFUSE.

To blanch Celery in cocoa-nut fibre place a straight row of laths, barrel-staves, or old pen-sticks on end in the earth on each side of the Celery. Allowing 4 inches from the Celery these two fences will be about 1 foot from each other, and they should be as high as the Celery is required to be blanched. Then with the refuse fill up on each side of the Celery, and be careful of the centre leaves. Slope the materials outwards from the plants, so that heavy rains may pass by the outside of the row into the trench. The fibre keeps the Celery in good condition longer than anything I know, either during a mild or severe winter. No worm of any kind touches it. The flavour is very much improved, and the plants are dug up with ease.

If the fibre is considered too expensive, keep it in a shed from year to year, or in a dry corner—not over the roots of trees, because roots revel in it, and in a short time they would convert it to their own nourishment. If there is no other convenient keeping-place, use four sheep-hurdles on edge in a square to keep it together, or dig a pit in the earth. But to keep it long it must be dry. Ten shillings worth in Kingston would blanch three hundred heads of Celery annually for five years. One trial of this will remove every doubt and objection.

I have tried moss, sawdust, straw, fern, ashes, and sand, yet am convinced that no person will use for Celery-blanching anything we know of at present, after trying the fibre refuse. I will add that cocoa-nut fibre refuse in preparing large trees for transplanting is invaluable. Every species of tree roots rapidly in it, and it adheres to the roots, rendering the balls of earth one-third less in weight, and the trees recover more speedily from the check arising from removal.—JOHN BASS, *Sarbiton*.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE November meeting of the Entomological Society was presided over by F. Smith, Esq., the President; and amongst the donations to the Library received since the last meeting was Mr. Thomson's work on the Scandinavian Coleoptera; Colonel Metchulsky's "Etudes Entomologiques;" and some Numbers of Mr. Wilson's "Farm and Garden," published at Adelaide in South Australia. Mr. Bates, the distinguished traveller in the Amazon district of South America, and author of some of the most remarkable entomological memoirs which have recently appeared, having been proposed as a member of the Society, the ordinary rules relative to the election of members were dispensed with, and he was at once unanimously elected a member by acclamation.

The Secretary read a requisition which had been submitted to the Council to be taken into consideration at the

January meeting, with the view to alter several of the bye-laws of the Society relative to the working of the Publication and Library Committees, honorary members, &c.

The President exhibited the nest of *Trigona carbonaria*, the small stingless Honey Bee of Australia, and which appeared to consist of a large mass of waxen materials formed into branches and stems, resembling corallines; amongst which, on the outer branches, were attached a number of oval cells, filled with honey, resembling the honey-pots of the humble bees. The nest, however, was fixed within a box, so that the interior could not be examined. It had been received from Queensland, by Mr. Woodbury, so well known to the readers of this Journal for his excellent observations and experiments on the honey bee of this country, and by whom it had been transferred to the British Museum. The President also exhibited the mass of hexagonal cocoons formed by *Tenthredo* (*Deilocerus*) *Ellisii*, a South American kind of Sawfly, which had been described and figured by the late Mr. Carter in the Transactions of the Linnæan Society. It was remarkable as showing that in a family so far removed from the Bees as the Tenthredinidae, a similar kind of cell was formed by the larvæ when working in society.

Professor Westwood alluded to nearly similar details in the cocoons of the social *Microgaster alvearius* and the masses of cocoons of *Ilythia sociella*. The hexagonal form of the cells in these nests led to considerable discussion, as to whether it was an instinct inseparably associated with the construction and existence of the insects by which these nests were formed, or merely the result of the juxtaposition of the cocoons or cells.

The President also exhibited some specimens of the small Ermine Moth, *Hyponomeuta padella*, stated to have been reared from larvæ found on unripe ears of corn in Suffolk, every grain having been attacked by the caterpillars, and the Moths having been produced in the box in which the caterpillars were placed. It was, however, the general opinion of the members present, that there must have been some mistake in the circumstances connected with the development of these Moths, the caterpillars of which are generally found on trees.

Mr. F. Bond exhibited a drawing of the caterpillar of the Sphinx *Convolvuli*, found on the small Bindweed, on the 17th of September, at St. Leonard's; also a beautifully preserved specimen of a remarkable dark-coloured variety of the caterpillar of the Death's-head Moth, taken on the Ash, prepared by Mr. Baker, of Cambridge, who has acquired the art of preserving caterpillars with great success.

Mr. F. Moore exhibited some impressions of the wings of Indian Lepidoptera taken upon waxed paper; and Mr. Francis specimens of the rare *Anthrribus albinus*, taken at Folkestone, in September.

Mr. MacLachlan exhibited an interesting series of the cases formed by the aquatic caterpillars of the different genera of British Trichoptera or Caddice Flies. In some cases the small tube of silk was coated with particles of stone, in others with shells, in others with small twigs, and in some with these materials combined; each species having a special method of its own for the formation of its case, the species of the genus *Setodes* enclosing only silk in their cases.

Professor Westwood exhibited a large sheet of a white silken tissue found at the bottom of a biscuit-chest, the contents of which had been attacked by larvæ, which had been supposed to be those of some Dipterous insect. It was, however, considered by the members present, that the tissue was spun by the larvæ of some Lepidopterous insect, probably *Tinea granella*, not as a cocoon, but as a carpet to enable it to creep along with greater facility. The specimen had been communicated by Dr. Cathbert Collingwood.

Mr. G. R. Waterhouse exhibited specimens of a small Beetle from the Kirbian collection, labelled as *Seymus bis-bipustulatus*, of Marsham, which Mr. Waterhouse regarded as identical with the *Seymus quadrilunulatus*, of Mulsant.

Mr. H. T. Stainton made some observations on the six European species of the genus *Cosmopteryx*, comprising some of the most beautiful species of Microlepidoptera, the of which are natives of this country, including *Tinea exima* and *T. Druriella*.

WELTON PLACE, NEAR DAVENTRY.

ANTIQUARIES, like the mummies and other relics with which they are conversant, are proverbially dry fellows, and no exception to this characteristic was the trustworthy antiquary of Northamptonshire when he wrote of Welton Place,—"It is a commodious residence, pleasantly situated on a gentle elevation west of the village." These are facts, certainly, but they are very dry facts, and give no more correct idea of Welton Place than would the statement that the Venus de Medici is "the figure of a naked woman with her head inclined on one side." Let us enter a little more into detail; but before doing so we must indulge in a thought forced upon us, that this Daventry and its vicinity appear more than most localities to have been the seed-bed and harvest ground of plots and revolutions.

We spoke two or three months ago of Fawsley, and its connection with the Cromwellian revolution. Not far away is Naseby and Holdenby, the fatal battle ground and prison of Charles I.; Kenilworth, so associated with the evil days of Amy Robsart, is within a few miles; still closer is Catesby, whose owner was so connected with the Gunpowder Plot, and this Welton Place had for its lord another Catesby, who bowed down before the headsman for being the partisan of Richard Crookback, from the murder-night of the Princes in the Tower until his last struggle on Bosworth Field.

The present lord of Welton, however, is not likely to become implicated in any such undertakings. His pursuits, though more obscure and less stirring, are far more ennobling and peaceful; and when we state that this same lord is none other than Major Trevor Clarke, the ardent horticulturist and successful hybridiser of several important genera of plants, our readers will be able to form an opinion as to the "goings on" at Welton.

The house is "pleasantly situated" on a high elevation, the ground falling away from it rather abruptly to the east and the north. On the latter side, and immediately in front of the house, is a large sheet of water clothed with the white and yellow Water Lilies, and very tastefully planted round the margin. Here and there beautiful landscape effects are produced, stretching far away into the fine old timbered park beyond, and these heightened by the introduction of some of the best Conifers, such as *Cedrus deodara*, *Cryptomeria japonica*, which succeeds admirably near the edge of the water; *Abies Douglasii*, *Pinus excelsa*, and several others.

There is no attempt at what may be called the modern school here. No "bedding-out," no "polychromes," no blazes of colour; but there are good examples of the old-fashioned botanico-horticultural style, where there is a fine collection of curious plants now never seen in modern establishments, and which are grown for the love of them. Here, too, experiments are conducted of all possible kinds in culture and hybridising; and those who can appreciate scientific gardening rather than garden decoration, will find here much to amuse and to instruct them.

Unfortunately, when we called Major Clarke was from home, and we were consequently deprived of the key to much that would have been interesting to us. Still, however, we made the most of it, and remarked a great deal that required no illustration.

The principal glass structure is a half-span botanic stove 60 feet long by 18, and about 16 feet high. Down the centre runs a long bed built after the fashion of a tan bed, but is now covered in with perforated malt-kiln quarries supported on short brick walls, and heated by a hot-water tank upon Weeks's principle. This forms a central stand for tall tropical plants in large pots, which thrive remarkably well on this warm floor, while a continual current of moistened air rises through the pierced quarries. A part of this bed or pit is converted into a tank through which the hot-water pipes pass; and this again is surmounted by a tall piece of rockwork. In front of this is an ordinary plant-stage; and behind it, shaded by the tall tropicals, are grown a select lot of Ferns, Orchids, and other shade and moisture-loving plants. The back wall is allowed to be as damp and moist as possible; and is covered with a perfect crop of seedling Ferns, with Orchids and epiphytes of various kinds. The house is kept at a low temperature with much ventilation, especially at night; and was designed by the owner to grow plants from all climates, and as a

convenient place for horticultural experiment all the year round. A great number of species, and many rare and curious things, are collected here—more than met the eye, in fact, and the owner was not there to explain. A few handsome specimens of plants of interest, such as Cinnamon, Ginger, Nutmegs, and Cloves, with Pepper and Allspice, Arrow-root and Rice, Tea, Coffee, Sugar, &c., were visible signs of the peculiar taste of the owner; and a plant of Vanilla rambling about the rock, with *Renanthera* and other strange things, had taken to the rafters, and is bidding fair to be in a condition to flavour the Coffee. Many of the plants, large and small, were turned out to grass in the experimental hot border out of doors. Bulbs and Scitamineæ were well represented. *Mantisia saltatoria*, *Canna iridiflora*, glauca, and flaccida, *Coburgia* in bloom, *Stenomesson breviflorum*, and other rare Chilians, and *Crinum Forbesianum* were noted, with the rare and curious Water Sensitive Plant *Neptunia plena*. Cotton plants of various kinds were being crossed with a view to producing improved sorts for cultivation in India, the result of which has recently appeared in the pages of our contemporary; a sufficient number of such things as *Ficus*, *Dracæna*, &c., to give ornament. The houses contain three water-tanks besides the central one. One of these, in a shaded part of the house, was backed by rockwork alive with Ferns, and overtopped by a huge growth of *Philodendron* in fruit and blossom. Water is laid on, so that the rockwork parts are made dripping at pleasure.

After the range of houses, the subject of greatest interest is the geothermal-bed, or, as it is, we believe, sometimes called, the tropical garden. This bed is on an elevated terrace a little higher than the range of houses, and is fully exposed to the atmosphere. It is 21 feet long and 9 feet wide. The whole bottom of the bed is a hollow chamber, upon which the soil rests, 18 inches deep. All round this hollow chamber is a three-inch hot-water pipe connected with a Burbidge & Healy's boiler, and this forms the heating arrangements. In this bed we observed fine specimens of *Aloe arborea*; an immense Cockscorn, 15 inches across; Bamboos; and a thriving Sensitive Plant. *Stephanotis floribunda* was making a fine growth, as was also *Mandevilla suaveolens*, which had every appearance as if it would bloom in September. Of *Ficus elastica* there were fine, tall, robust plants, as there were also of *Datura arborea*, *Poinsettia pulcherrima*, *Jasminum Sambac*, and numerous *Cannas*. *Aralia papyrifera* appeared to do better here than it did in-doors, having made larger foliage, and *Richardia athiopica* stood out all the winter, forming stout, stocky plants, and making luxuriant growths.

In the kitchen garden is a noble standard Apricot tree of the true Brussels variety, which had an excellent crop on it. Here we also observed a novel method of treating the White Rocket Candytuft. It was managed much in the same way as the large *Chrysanthemums* were, which this season so astonished the *habitués* of the South Kensington Conservatory. All the side shoots were pinched off as they appeared, and the plant trained to a single stem, which was terminated in consequence of this treatment with a spike of unusually large flowers, 6 inches long, like that of a Hyacinth.

After strolling about till we had seen all the gardening matters, and just as we were about to leave, the gardener asked us if we would like to see Lady Pearson's wilderness. After such a gardening treat we thought we did not care much about a wilderness, and so thanking him we declined, determining to return with all speed to Daventry. "It's well worth seeing, sir," said the gardener. "Her ladyship takes a great interest in it, she has half a dozen men always doing something to it." At this intelligence we were somewhat interested, and wondered what sort of a wilderness it could be that had half a dozen men always doing something to it; and so we recanting, agreed just to have a look.

Entering by a small wicket near the north-east corner of the mansion, we were led along a narrow winding path, not more than 5 or 6 feet wide, which, if we recollect rightly, becomes narrower still as we proceed. After travelling some distance we turned sharply to the left, and entered what appears to be a rustic summer-house, and there "the wilderness," as represented in our engraving, bursts upon the eye. "Do you call this a wilderness?" Yes, sir; that's what her

ladyship calls it. "And is it natural or artificial?" we inquired. "It's all her ladyship's own work, sir; she did it all herself."

At this moment Lady Pearson, who is Mrs. Clarke's mother, and who resides at Welton, entered "the wilderness," and received us with every mark of kindness and welcome. We were now in a fair way of knowing more about the wilderness, the history of which is as follows:—

Some years ago, when Lady Pearson came to reside with Major Clarke, she requested that she might have a piece of ground in any waste corner where she might do just what

she liked, and with no one to interfere with her. Being a lady of great taste, with a correct eye for the beautiful, and withal of great mental as well as physical activity, Lady Pearson set about creating—not adapting, nor altering, but—literally creating this "wilderness," which now abounds with so many fine landscape effects. The spot which is now occupied with the subject of our engraving was formerly a sort of rubbish-corner in the park adjoining the high road and the village; and the building, which everybody would take for a rustic cottage, was, and we believe is still, the end of a stable or some such structure. How the scene has

been changed our readers can imagine from our artist's representation of it. But this is only one corner of "the wilderness."

Following the path which leads past the cottage and under the rustic bridge we followed the stream, and bearing round to the right we encountered a scene of far greater extent and of a bolder character. In the foreground is a Swiss cottage with its rustic gallery and overhanging roof; and here her ladyship has an aviary of rare and interesting birds, a museum, and picture gallery. The scenery all round this cottage is varied and beautiful in the extreme;

the water is skilfully disposed; here as a miniature lake with a sinuous and now and then retiring outline, and there running off in a lively babbling stream, making music as it flows. Still continuing our course beyond the Swiss cottage we enter a bold rocky region rising precipitously all round, the monotony being broken by the advancing and retiring outline, the shady nooks, and the tasteful style in which it is planted. All natural effects are here represented. Entrances to caverns, by the fidelity of their representation, seem as if they penetrated far into the hill, and attract the curious merely to find that they are not a yard in depth.

Large fissures gape as if in agony from some great internal convulsion. Shelving rocks jut out in threatening aspects, and every part of the illusion is so well sustained as to call forth all one's admiration. The planting also is faithfully and tastefully managed; and we can conscientiously say that we never saw a piece of artificial landscape that afforded us greater gratification, or which reflected greater credit on the designer.

GREENHOUSE BLINDS.

As the time is now approaching when winter blinds and mats will be put in requisition, the following hint may not come amiss to some of your correspondents.

In "Greenhouses for the Many," page 11, is a description of a roller blind for a greenhouse roof, and the author remarks, "There is some little accommodation [observation?] required to learn how best to get the far end of the pole to reach its destination at the same time as the near end," &c. But he does not tell us how to do it, and the natural tendency of the blind to wind up "slantindicular," as Americans say, is very annoying, besides the risk run of the pole smashing the glass unless there are several bearers (see fig. 1.).

Fig. 1.—My former Style.

Having, within the last few days hit upon a very simple mode of overcoming this difficulty, I beg to offer it to your Journal, as it may be of service to others. I do not think the author of the above could have been aware of it, or he would certainly have mentioned such a simple contrivance.

The improvement consists merely in fixing on the "far end" of the roller a disk of wood, as shown in the sketch (fig. 2, E).

Fig. 2.—My present Style.

It will at once be seen that, as the roller blind revolves, any tendency of the pole to get out of the right line is immediately checked by the wheel pressing against the bearer (A), and the pole is forced to ascend properly—*Voilà tout*. "Simple comme bonjour," as Balzac says.—*LEX.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

Broccoli, the weather, up to the present time, having been so favourable to its growth, it is advisable to dig it up, and lay it in trenches in nearly a horizontal position, covering the roots and stem up to the leaves: this has the effect of checking its luxuriant growth, and of protecting the hearts of the plants in severe weather. *Cabbage*, earth-up, if not done, the weather now being favourable for that purpose. *Carrots*, if young ones are wanted very early, seed should now be sown on a slight hotbed. *Endive*, take advantage of the present fine weather to tie-up and house a quantity. *Radishes*, every fine mild day draw off the lights entirely this will give them strength to form bottoms.

FLOWER GARDEN.

This is a season of the year which may be turned to good account by taking a retrospective glance of the labours of the year that is passing away. To profit by such an examination it ought to be done most faithfully and most strictly. Where you find that anything which would have added to the attractions of this department has been omitted during the past season note it, and resolve that it shall be attempted in due time; recollect what has been improperly performed, and make up your mind that it shall not be so when another opportunity shall present itself. You may have been prosecuting a plan which has proved unsuccessful; consider if it is worth trying again; if so, persevere during the ensuing season, and your efforts may be crowned with success. Where the tenderer varieties of *Roses* are found to require protection, this should be applied at once, if not already done, otherwise it may soon be too late to save them. The leaves being all thoroughly cleared and removed, the next thing to be thought of is to take advantage of frosty weather (when other operations are temporarily closed) in running the saw, chisel, and knife through the overgrown shrubs, not with the idea of destroying the picturesque character of shrubs and evergreens which have reached their full expressions, but in order to protect the more delicate from the tyranny of their stronger neighbours; to remove dead branches, and to preserve a due right of passage through the plantation walk. The very mild season has already caused early or shallow-planted *Tulips* to show above ground; it is advisable as soon as observed to put a small quantity of heath or any other light mould over them, to protect them from frost and cutting winds. This may not be applied regularly over the bed, but in small cones over each plant as it shows itself. *Carnations* and *Pieotees* being now in a luxuriant state should be carefully examined, the foliage in some situations is apt to get spotted. As soon as this is observed remove the diseased leaf with a pair of sharp-pointed scissors, or the disease will spread through the stock most readily. Examine the axils of the foliage, dust and dirt are apt to lodge therein, this should be carefully removed. *Polyanthuses* are showing flower, the trusses to be removed as they appear, and the plants in pots to be placed in a northern exposure.

FRUIT GARDEN.

Some wall trees, as *Pears*, *Plums*, *Cherries*, &c., are often attacked by scale, in which case the infected trees before they are nailed should be washed with water of the temperature of 160°. Gishurst compound applied in the shape of a strong lather has likewise been found to be a cure for scale on fruit trees.

STOVE.

Here all should be still and quiet. Keep a moderate heat of from 50° to 60°, and give plenty of air. The *Ixoras* to be elevated near the glass to set their bloom, and to have plenty of air at all favourable times. Keep them comparatively dry. *Stephanotis*, *Allamandas*, &c., may be potted and trained preparatory to staking after Christmas, and the staking of all succulent plants to be proceeded with as fast as possible.

GREENHOUSE AND CONSERVATORY.

The weather has been so highly favourable for hardwooded plants that many of them are growing as freely at the present time as if it were September. As this young growth will be found very tender, abundance of air must be given to the plants, and great precautions taken to guard against King Frost's stealing unexpectedly a march upon you, as

a slight frost in the present tender state of the young wood would do very serious injury. When, however, you guard against frost, take care also to avoid overheating the houses, and give all the air possible at every favourable time. Water cautiously and in the morning, but take equal care not to allow any plant to suffer from the want of it. Look well to plants in a growing state, such as Pinelcas and all the New Holland plants.

FORCING-PIT.

Introduce such plants as are generally used and frequently recommended for forcing, especially the sweet-scented as Lily of the Valley, Sweet Briar, Lilacs, Roses, and bulbous plants. All plants intended for forcing in succession should be under temporary covering of some kind. An open shed is as good a place as they can be put in, or under the stage of the greenhouse.

PITS AND FRAMES.

The abundance of light with which the plants in these structures have been favoured (there having been scarcely any need to have recourse to protective measures in the shape of covering), combined with the mild weather, has excited growth, and a disposition to grow long and straggling. To counteract this some attention will be required on the part of the cultivator; a stiff dwarf habit is easily attained by a frequent use of the finger and thumb. Geraniums, Ageratums, and Calceolarias are very liable to become damp and mouldy; remove all mouldy leaves as soon as they are discovered, or they will be certain to contaminate others, and thus spread disease over the whole pit or frame. It is necessary, in order to keep flower-garden plants in first-rate condition, to give them a limited supply of water, abundance of light, a free circulation of air, and a dry atmosphere. Abundant preparations must take place in this department; a good stock of garden mats to be procured and tied for covering purposes; labels rewritten; and seed-drawers thoroughly examined, cleaned out, and the old seeds dated and classified, in order that their relative value may be readily known. The new seeds will, of course, want arranging.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

VERY much the same kind of work in all departments as last week. Raked leaves, trenched-up ground, removed covering from Sea-kale in Mushroom-house, as it was coming faster than we wanted it. Placed a few barrowloads of hot leaves close to a mound of Rhubarb in the same place, which was not coming quite so fast as wanted, and the additional heat about the large roots has acted almost like magic. Placed a lot more of Sea-kale in pots in Mushroom-house; the advantage of which is, that we can give heat round the pots as we like, and if not wanted for use we can move the pots to a cool, dark place, or make it dark for the Kale by putting a pot overhead, and filling up all the holes. It is much better to do this than allow the Kale to be long and lanky. From 6 to 8 inches is a good size, and the thicker and firmer the leaves the better it will look at table. Put in a succession of Mint and other herbs likely to be wanted green, where there was little heat. Have had some gatherings of Peas from an orchard-house, but though there are plenty of blooms, they do not seem to set in dull, cold weather. Of course, with a little dry heat, they might be had all the winter. Earthed-up Dwarf Kidney Beans in bloom in pots in a little heat, and potted off some more. It is more handy having them in pots now than planting them out. At this season they like a little dry heat. When growing them largely after January in a heated pit, we used to sow a succession as soon as the first showed flower-buds, sowing in rows 2 feet apart, and earthing-up. By the time the first was half gathered we sowed in the furrows, and the plants were up and strong before we pulled the first ones up to earth-up what would be the third crop, and so on with the others. By such close work with a pit of from four to six lights, we could keep a regular succession until we obtained a supply first with a slight protection, and then out of doors. Earthed-up a piece of Mushroom-bed, and set another piece preparing. Have done nothing with Chicory, as Lettuce and Endive are abundant. Cauliflower is also

still plentiful in sheds and under glass. Stirred the ground among young Cauliflowers, Lettuces, Cabbages, &c. Will place some burnt earth and rubbish among these young plants as soon as we can get at them. Gave abundance of air to Radishes, Lettuces, Cauliflowers, &c., in frames, when the weather was fine. In cloudy, hazy weather elevated the sashes back and front, that there might be a good draught through.

FRUIT GARDEN.

Examined the Strawberry plants placed in frames with a slight hotbed of leaves under them. Found the heat nice and mild. It will be recollected that the pots were merely set on the surface of the bed in case there should be too much heat if plunged. As the heat is mild, and that the sides of the pots may feel the benefit of it as well as the bottoms, stuck some dry leaves in the openings between the pots without moving them. The plants are just moving, and as yet need no water, and will not likely need any until they are moved into dry heat. Watered a few Black Prince placed in a narrow Vine pit. Watered the Vines there, too, with warm water; and as the temperature at night will average 55°, will remove other plants, such as small Geraniums, &c., and fill as undergrowth with Dwarf Kidney Beans. Syringed these Vines twice a-day, oftener if the sun was bright, the syringing doing no harm to the leaves, though it would to bedding plants. As the days were dry wheeled out wasted manure from earth-pits and frames, leaving all matter that from not being decomposed would heat again, especially when mixed with fresher material, and used the manure for mulching newly-planted dwarf standard trees, to keep the roots near the surface, and for placing between the rows of Strawberries, the ground having previously been stirred up with the points of a fork. This manurial matter is put a little in the ridge-form between the rows, and, therefore, breaks the force of the frosty winds; whilst the virtue, what little there may be, is washed towards the plants. For tender kinds, such as the Queen, if severe frost come, a few short evergreen boughs stuck between the rows will be of great benefit. Earthing-up the crowns a little is also an advantage. If severe weather should come we will place some burnt earth and charred rubbish close to the crowns, which will not only secure the lower part of the stems from exposure, but help to keep slugs, &c., at a distance. A Dutch hoe run through the manure between the rows will make all smooth in the spring.

We may here further state, in answer to several inquiries, 1, That a stiffish loam is the best of all soils for Strawberries. 2, That light sandy soils should not only have extra manure, but should, after trenching, be trodden well before and after planting. 3, That in making a plantation, if the depth of the soil will permit, it should be trenched to the depth of two or three spits, keeping in mind what was said on trenching last week. 4, That in trenching a good supply of manure, not more than half decomposed—say a thickness of from 8 to 12 inches—should be used, and that not turned in in layers, but intimately mingled with the soil as the work proceeds. 5, In addition to this, when the surface is nicely aired and levelled, a little leaf mould or very rotten dung may be spread on the surface when planting, so as to encourage vigorous growth at once. 6, The best time for planting is as soon as the strong-rooted runners can be obtained, whether by layering in pots or other means; the next best will be as soon after that as possible. In all small gardens there is often a difficulty in sowing fresh ground so early in the season, and where that is the case the best plan is to prepare a border or piece of ground by well stirring it, but not too deeply, and enriching it well with leaf mould and rotten dung, and inserting the runners in it, as soon as they show roots, at from 4 to 5 inches apart. Here they can easily get a little shading if necessary, and watering, and they will grow fast and strong, and may either be lifted with fine balls in the autumn, or as soon as the ground is in good order in the spring. When so done, as well as when planted out early, they will fruit the first season. We always adopt this plan to have a reserve in hand for forcing when those in pots might be exhausted too soon; and though it would not do for early crops, it does very well for a succession or two before Strawberries come in out of doors. 7, When a plantation is thus made, with the exception of a little surface-stirring and such surface-manning as referred to

above, no spade is ever seen near the Strawberries until they are dug down to make way for other succession crops. This is generally after the third season, and sometimes after the second season, especially after forced plants have been used instead of young plants. In general the ground will be managed more profitably if the crop does not stand after the third season. In many amateurs' gardens, however, there is a favourite corner devoted to Strawberries, and the owners do not wish to change it too soon, or they have a terror of the trouble of making a new plantation, and what they are pleased to consider the uncertainties, instead of what we would deem the certainties of success; so that instead of doing anything in the way of a new plantation, they would be glad to do anything and everything to obtain a fair crop from their old plants, or, at least, from plants on the same ground. There are various modes by which such an object may be gained. We will instance two modes: First, where the same ground is to be used, but fresh plants. The plants at first were put in rows 2 feet apart from row to row. These bore from two to three years. The space between the rows was then stirred up and well covered with short dung, leaf mould, and a little lime dust. The runners were encouraged to root into this, were thinned out where too thick, and when well taken the old rows were trenched down and manure added. The process ultimately was repeated whenever the crops were taken. The proceeds were all that could be wished, and we were informed that in one place the same ground had produced Strawberries for nearly twenty years. The second mode is keeping to the old plants, and this we have often practised. In clearing away the runners as soon as possible, a number of the smaller stems with the weakest buds were also removed, so that light and air should tell as powerfully on the old shoots as on younger plants. The ground was then slightly surface-stirred, and surface-dressed with manure. We recollect one instance of a fine crop, and the old gardener told us it was the fifteenth he had obtained from the same plants, and the above was chiefly his plan of working. We forget now the peculiar reason why these plants should be kept as long as they would bear. With manure-dressings, soot-dressings, manure-waterings, &c., which these plants received, along with the thinning of the buds on the old crowns, we see nothing to prevent Strawberry plants lasting scores of years; but unless for particular purposes, desires, and for convenience, we should see no benefit in such a system, as a part of the garden at least would be deprived of all the advantages of a rotation of crops. 8. We see there is one more complaint we have not alluded to. "Our ground is light, Strawberry plants grow well, and bloom well, but we scarcely get any fruit." Make your ground firm this spring by treading, even if you should add some more earth between the rows. Mulch well with rotten dung to give nourishment and keep in moisture, and when the plants are coming into bloom if you do not have a heavy drenching from the atmosphere, give the rows a good soaking of soft water, and if not too strong, if the water comes from the drainage of a dung-hill, house sewage, &c., so much the better. If before the natural waterings from heavy rain, or the artificial waterings you give, you strew the ground with soot and lime, the plants will be still more benefited, and worms and slugs will not be so apt to disfigure or make holes in the fruit. Follow the above plan, and we shall be surprised if instead of having no Strawberries for yourself, you will not be able to have the pleasure of sending baskets and punnets to those who have no chance of growing this valuable fruit.

ORNAMENTAL DEPARTMENT.

Much the same, as respects routine, as last week; but chiefly engaged on fine days in looking after all small bedding plants, giving abundance of air, and removing all traces of damp. In some cold pits and frames put some dry charred rubbish at the bottom for the pots to stand upon, and moved some of the more tender into places, where, if necessary, a little dry heat could be given. Gave a little fire heat to the conservatory and other places several times during the day, that by giving more air there might be a greater drying circulation. Gave no water to plants in cold frames or pits, except when absolutely necessary, as if frost should come the drier the herbage, and the soil too if just moist enough, the less will they be likely to suffer. The

earth pits and frames now being emptied of the decomposed manure, will be filled with fermenting material for forwarding many things.—R. F.

COVENT GARDEN MARKET.—Dec. 19.

We have to report a plentiful supply of all kinds of produce in season, and a full attendance of buyers. Good dessert Pears are rather scarce from preparations being made for Christmas. Of Potatoes the supply continues to be heavy. The various avenues to the market are now beginning to be blocked up by primitive-looking waggons bearing loads of Holly, Laurels, and other evergreens, which meet with a ready sale. Christmas trees, which have now become "an institution," are everywhere seen. Cut flowers are now more plentiful, and mainly consist of Camellias, especially the white, Roses, Violets, Chrysanthemums, Acacias, Christmas Rose, and numerous pots of the beautiful *Poinsettia pulcherrima* are also met with.

TRADE CATALOGUES RECEIVED.

Drummond & Sons, Stirling, and 58, Dawson Street, Dublin.—*Catalogue of Forest, Ornamental, and Fruit Trees, Roses, Shrubs, Conifers, &c.*

Edward, George, Clarence Nurseries, and 1, King Street, Castlegate, York.—*Catalogue of Fruit Trees, Roses, Pelargoniums, Carnations, &c.*

Sutton & Sons, Reading.—*Spring Catalogue, and Amateurs' Guide for 1864*, containing lists of Vegetable, Flower and Agricultural Seeds, Grasses, and Plants, with cultural instructions.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

PENTSTEMONS (*B. H.*).—*Purple*: Violet, Goliath, Mon Caprice, Orientale, Mrs. Lees, Kellermanii, John Fozgo, Monsieur de Porpat, Jaffrayanum, Azurea Verticillata, Clio, and Blue Beauty. The above vary in colour, from light blue to lilac and crimson purple. *Scarlet*: Vivid, Noble, Rose of England, Rubrum Magonifolium, Meteor, Illuminator, Mrs. Stearns, Robert Hiquet, Anabilis, Coccineum Magnificum, Brilliant, and Comte de Lambertye. We are not acquainted with any white, beyond Alba. Mrs. Hope, a light peach, with a white throat, pencilled with light crimson, is a good light-coloured flower. Many of the above have the throat white. The *Arbutus* is chiefly raised from seed; it may, however, be increased by layers. Evergreen Oaks are increased by sowing the acorns in March or April, and by grafting. Evergreen shrubs are propagated by cuttings made like any other description of cutting, and generally inserted early in autumn.

PEARS FOR AN EAST AND NORTH-EAST WIND (*J. W. L. S.*).—These will do well at Teddington—Glen Moreau, Knight's Monarch, Winter Nellis, Josephine de Malines, Henriette Bouvier, Zéphirin Grégoire, Jean de Witte, Bezi Vaet, Bergamotte Espere, Ne plus Meuris, Huyshe's Prince of Wales (or Huyshe's Bergamot), Huyshe's Victoria.

REMOVING SUCKERS FROM HYACINTHS (*E. S., Hampton*).—We make it a practice to take off the offsets when we pot the bulbs. If any appear afterwards we take them off with a knife close to the bulb, taking care not to injure the latter nor its roots. Offsets do nothing but rob the parent, and are best removed. You will apply this to your bulbs.

CHLVSANTHEMUS DONE BLOOMING (*Idem*).—Take away all the wood of the current year and turn the plants out of the pots, and plant in the open border. You may select the strongest of the suckers and pot them singly now. They should be headed or topped when 6 inches high—that is, if you wish to grow them on single stems; if you do not care about that, stop them now to obtain dwarfs or bushy plants. These will make earlier-blooming and larger plants than if you deferred parting the plants till March or April. If you part them now, the young plants will require to be wintered in a cold frame. Those divided in spring will do without that protection.

ESTABLISHING GRASS WALKS (*R. R.*).—We advise you to sod the intervening spaces between the beds, and think yourself well off that you have curves at command. You may sow lawn grass seeds in March as you propose, but you must not expect so good an effect as if the spaces were soded at once. In neither way would the grass be injured by treading in the ordinary course of proceeding, and in both it will be improved by rolling twice a week.

PLANTS FOR ENCLOSED N.W. WINDOW (*A. G. II.*).—The plants best adapted for such an aspect are Ferns; but we know of no climbers that would do well in their company except varieties of Ivy, some of which have highly ornamental foliage. *Lygodium scandens* and *L. palmatum* are climbing Ferns, and would, no doubt, do well in such a place. The roof should slope towards the front, and it will not matter if the slate if Ferns are grown, but glass would be better. If you are not particular as to Ferns the window might be planted with Hyacinths, Cyclamens, Tulips, Narcissus, and other spring-blooming plants, which would be charming in early spring; and in summer the bed might be filled with Geraniums and Fuchsias, with *Tropaeolums*, *Bouvardias*, and *Lophospermums* running up strings fastened to the roof, and about 6 inches from the window.

LIGHT CHALKY-SOILED FLOWER-BORDER (*Torridus*).—A dressing of salt as you propose will in some measure check the evaporation of moisture and scorching up of your plants in summer; but you require a more permanent and more effectual remedy. Can you not obtain earth from the parings of ditches, &c., so as to deepen the soil to 18 inches and improve its staple at the same time? Your "very shallow chalky soil" is worse even than a very clayey one for garden purposes. We should increase the depth and staple as we have said, and mulch the surface at least an inch thick in summer with coenunt fibre refuse.

AMERICAN BLIGHT (*A. Q.*).—We have used Gishurst compound at the rate of 8 ozs. to the gallon of water, and find it kills this pest. We apply it with a brush, rubbing or brushing it into cracks, holes, or crevices, and heated to 160°. Now is the time to apply it. It does not injure the buds unless the scales are rubbed off them, when the rubbing kills the buds quite as much as the compound. We have also found the following answer well:—Sulphur, lime, and soot in equal quantities formed into the consistency of thin paint by the addition of boiling urine, and this we apply to the trunks with a brush, rubbing it well into the crevices when cooled to 140°. The soil should be taken from about the main roots, and, if infested, these should be painted like the stems.

STOVE IN GREENHOUSE (*E. M. W.*).—Providing the fumes of the charcoal or coke can be made to pass into the tin pipe, we see no danger but what may arise from dryness. With the assistance of the blinds your stove should be sufficient to keep frost out. We advise you if you can burn coke in your stove to employ it, and if it emits a sulphurous smell you must make an alteration, as it will then be evident that the fumes which ought to ascend the tin pipe pass into the house, and these sulphurous fumes soon destroy vegetable life. Charcoal, on the other hand, when burning emits no offensive fumes that are appreciable to the senses, and therefore you must be cautious about it, for, should the gases escape from the greenhouse into a sleeping-room, it is possible the fumes might suffocate the inmates. Charcoal fumes also destroy vegetable life. Guano water made by dissolving 1 oz. in a gallon of water may safely be given to plants in a growing state. It is as good, if not preferable, to manure water, and can be applied more safely by an amateur.

VINES FORCING (*Liverpool*).—We fear you will not be able to grow Ferns and Vines successfully together. You might bring the Vines on until April in your fernery, when the fernery would require shading and the Vines removing to a house with more light and heat. We do not think there is any chance of your being able to grow Vines and Ferns together, but if you have other convenience besides the Fern-house, which would favour the removal of the Vines at the time above named, we advise you to have the Vines pruned at once and to seal the cuts with a red-hot iron and then seal the wounds or cuts with sealing-wax. The Vines should then be placed in the coolest part of the Fern-house until the buds break, when they cannot have too much light nor would the heat of your fernery be too much for them. Top-dress, but do not repot, and grow on in the fernery until the Grapes change for ripening, and then remove to a drier house to ripen. There is no better work than "Saunders on the Vine." It can be had from our office, free by post, for 5s. 2d.

STOPPING GERANIUMS (*A Subscriber*).—After this we would not stop Geraniums which were wanted to bloom early—say in April and May. For later blooming they may be stopped freely, especially all the stronger shoots. If these are freely stopped a shoot will come from the axil of most of the leaves left. Pretty close pruning in autumn and this stopping are the best means for securing bushy plants. This matter, often dwelt upon, may again be more fully referred to. The great object now is to prevent a few shoots stealing away the strength. For instance: suppose a good-sized plant has a dozen shoots, and three of these have more than double the strength of the other nine, then, if the three are pinched, they will each throw out two or three shoots, which will soon be as strong as the nine, and thus the strength is equalised.

COMPOST OF LIME AND MOULD TO GRASS LAND (*Catawbiense*).—You may apply this as soon in the autumn as the grass ceases growing and there is little left for the cattle to feed on, as it would be wasted by the dressing. Fifty loads would certainly be a good dressing for a Scots acre, but if laid on now we do not think it would kill any part of the grass. It laid on early in autumn, and the lumps exposed to frost to mellow them, it will all brush in with a ring or thorn-bush harrow by February.

CALEOLARIA VIOLACEA (*J. G., Whitefield*).—We think the plants are all that can be wished. They will be quite warm enough in a greenhouse that is seldom below 40°, and from which frost is excluded. Keep the plants in an airy position all the winter. Do not allow them to flag from dryness; but so long as the leaves keep fresh and firm, let the soil be dry rather than wet until the flower-trusses begin to show, and then water more liberally. We shall be much surprised if your strong plants will not be a sheet of bloom in April, May, and onwards. When done flowering the plants may be freely cut in, and when pushing freely be repotted in smaller pots by getting rid of a portion of the old soil. Cuttings taken off in autumn or spring make, however, the best plants. Those rooted early in spring will bloom freely the following year. Perhaps your plants have been kept rather vigorous. Let us know if your plants are not first-rate in April and May.

SYRINGING TREES OUT-DOORS AFTER DRESSING THEM (*N.*).—If you have dressed the trees with a mixture of Gishurst compound and water in the proportion of 1 lb. to the gallon, we should not by any means advise the syringing to be used until some growth takes place—say in the end of April or May. The object of dressing at this season with so strong a mixture is to kill all insects or their larvæ that may be lurking in the bark or about the tree, and to follow this up with a syringing of clear water would be simply to remove so much of the former as to render it less likely to perform the duties expected of it.

IRON DAHLIA-STAKE RESTING IN THE GROUND (*Catawbiense*).—We should advise the lower part of your stake to be held in the fire a short time to burn off the rust, after which coat that part, especially that which is at the surface of the ground, with creosote or coal tar to which a little grease or oil has been added, and the whole made warm. The remainder of the stake we should advise to be painted a lead colour, which is both durable and, in our opinion, looks better than green, the last-named colour being, perhaps, the very worst for lasting. We are not in general advocates for iron Dahlia-stakes. Wooden stakes, to our mind, look better; but where the former exist painting must be resorted to, and in doing so our aim has been to obtain a quiet unassuming colour and to avoid both white and green in the attempt.

CONSTRUCTION OF A GREENHOUSE-VINERY (*A Six-years Subscriber, Hammersmith*).—We do not clearly understand your description, especially as to the height of the proposed glass case and the height of the floor of the said case above the level of the outside ground, or the mode of communicating with the proposed house except the window of the dining-room is made into a door, or how to get to the garden in front except by another door, and steps leading down to it. Besides, you seem resolved to make such a very superior thing of it, that you would require to think the matter over carefully and have an estimate from a builder in your neighbourhood as to the expense. 1st, It is such a complicated affair; and as without great trouble you must have some fastenings to the walls and posts in the ground, and yet you wish the whole to be portable, we would say advisedly, do nothing whatever without a clear understanding with your landlord, and also a simple written agreement—there are so many quirks in the law in these matters. A farmer has lately put up a large glass house at the end of his farm-house, thinking he could move it when he liked; but there can be no doubt, from the way it is built, that the landlord can claim it if he chooses. A curate put up a small house at the back of his residence, and that he can move, as it is built in pieces and has merely blocks of wood for a foundation; but being a lean-to, a ridge-board was screwed to the wall just under the upper-floor windows. To this the rafters were screwed by one end, and fastened to the plate in front. By unscrewing from this plate, which could be left, the whole house could be moved easily, without even leaving a hole in the ground to fill up. A little nice sand did for the paths outside, and the whole being wood and glass there was no difficulty. To do much the same, you would require a strong framework to support the floor of the house, as well as the house itself. 2nd, This secured, there would be no difficulty in planting the Vines on the lower level, growing them as long as possible; and as soon as they are long enough to get up to the house, disbud all the stems, and cover them with a narrow wooden box packed with sawdust. They would do admirably in the wide part of the house, and might be trained longitudinally in the narrow part and thus give a nice shade there. The best sorts of Vines would be one Buckland Sweetwater, two Black Hamburgs, and one Muscat Hamburg. 3rd, These would do well even without the stove, but would do better with it; and were there no opposition you could heat the place easily from the kitchen boiler. The artificial heat would be all the more necessary from the very warmth of the place, as things will be apt to be excited by the heat, and will therefore suffer more easily and readily from cold. 4th, The Hartley's patent will be the best, but it will be more expensive, and for 21 oz. the sash-bars must be strong. The front glass might be common plate, and that you could easily shade. The shelves, if lined with zinc as you propose, will be all the better; and if the floor is made of well-seasoned timber, well rabbeted, it will be sufficient. The syringing will do it little harm as it will soon dry, and a little dust and wa-hing will fill the seams. 5th, With so many things to consider, it would be impossible to give such an estimate of expense as would come anything so near as you might obtain from a glass-house builder in your own neighbourhood, or at Chelsea. We have frequently stated what such buildings have cost; but with every desire to oblige our readers, the giving estimates for supposed circumstances would be as thoroughly impossible as planting the numerous flower gardens submitted to us. We may assist, give opinions, and criticize; but we cannot do more.

BOOKS (*H. B. L.*).—There is no such periodical as an illustrated Florist published weekly, nor any other so published on gardening, except this Journal, which has illustrations. Mr. Hereman's book relates chiefly to the culture of fruits under Sir J. Paxton's form of glass houses. It is to be had at Mr. Hereman's office in Pall Mall.

PELAGONIUMS, CAMELLIAS, AND AZALEAS (*J. P.*).—The following are the names of twelve *Pelargoniums*, cheap and good:—Carlos, Lord Clyde, Lady Taunton, Patroness, The Belle, Conspectum, Mrs. Hoyle, Roseum, Lady Canning, Celeste, Norma, and Leviathan. *Camellias*: Old Double White, Fimbriata, Imbricata, Candidissima, Duchess of Orleans. *Azaleas*: Sir C. Napier, Stanleyana, Gleditschii, Variegata, Ivoryana, Indica alba, Optima. We never recommend tradesmen. Look into our advertising columns.

ZONALE, OR HORSESHOE GERANIUMS (*S. O. U.*).—Geraniums having a black band on the upper surface of their leaves are so called. Tom Thunb, Commander-in-Chief, and Bishopstowe Scarlet are examples, but not Punch.

THE SMALL GARDEN AT TRENTHAM (F. E. M.).—To lay down the figure, of which we gave a representation at page 394, the space enclosed between the Privet hedge should be a blunt oval, the diameters of which would be 80 feet and 74. Then the central oval would be 18 feet by 14, all the rest of the figures round it may be curved lines next the oval as in the heart-shaped figures 3, and the paths between them and the oval 5 feet all round—the same width being allowed for the path on the outside of these figures. The pathways between these beds, as between 3 and 5, 6, would be about 3 feet wide; the four heart-shaped figures would be 14 feet by 10 at greatest width; the four circles would be 7 feet in diameter. If your ground were only half the size—40 feet by 37—the figures and walks would just be half the size, the centre 9 by 7, and the hearts 7 by 5. The two circular walks would be 2½ feet and the inner ones 1½ foot wide. A piece of ground, 54 feet by 50, would be two-thirds of the size first spoken of, and would look very well. It would be more easily laid down if the centre were a circle instead of an oval. Thus, fix on the centre, describe the circle, and run a line round for the outside of the eight figures. Place two lines across the centre at right angles with each other, so that the four ends shall come in the centre of the four path openings into the garden, and this will give you the four points of the heart-shaped figures. Place other two strings diagonally at equal distances from these right-angled lines, and on these fix the centre for the smaller circles. The figure will then make itself. We have great pleasure in answering this because there has been so much trouble taken in giving the references. Let us add that if the plan is followed strictly—Privet hedge round the outside and all—that hedge should be proportioned in height and width to the size of the figure. At half the size first spoken of the height should not be more than 8 inches.

CHRYSANTHEMUMS FOR EXHIBITION (Gallier).—We hardly understand what you want, and you seem to be in the best way to get rid of your difficulties; but, if you want our opinion, we say decidedly that Chrysanthemums ought clearly to be shown on one stem. We think, too, that the more naturally they are grown the better. Some staking must be used, but it ought to be as little as possible and to be concealed as much as can be.

PLANT-CASE HEATING (Sigma).—Heated by hot water, the only mode of raising the temperature of the interior above 60° is by having some part of the floor uncovered by earth, so as to allow the heat to rise more freely. We employ a plant-case heated beneath the soil by Child's night lights, or rather kept from getting too cold; and at night we put a woollen cover over the glass. We know nothing about the book you name.

VIOLETS NOT FLOODING (J. L.).—A free and rich soil, with shade or a deficiency of light and air, will produce the superabundance of leaves you complain of. Too moist and warm an atmosphere produces the same result. At this season no more water should be given than just sufficient to prevent flagging; and if they have abundance of air, and be placed on a shelf near the glass—for we presume they are in pots or in a frame—we should think they would flower. A moderately rich and rather light loamy soil, with perfect drainage, suits the Violet well. In the absence of particulars, we are unable to reply fully to your query. Inquirers would be doing themselves a kindness by giving more details.

STOVE PLANTS BLOOMING IN EACH MONTH (A. S. S.).—*January:* Aphelandra cristata, Epiphyllum truncatum (vars), Eranthemum pulchellum, Gardenia eltioides, Hebeclinium atrovirens, and Euphorbia jacinthiflora. *February:* Franciscia confertiflora, Vriesea splendens, Thyrsacanthus rutilans, Euphorbia splendens major, Stenogaster concinna, Pycnostachys utriculifolia. *March:* Incanthophyllum miniatum, Franciscia eximia, F. angusta, Gardenia radicans major, G. florida, and Cyrtanthera magnifica. *April:* Centradenia floribunda, Ardisia crenolata, Gesnera macrantha purpurea, Thunbergia Harrisii, Hibiscus roseus grandiflorus, and Hoya carnea. *May:* Echinanthus pulcher, E. splendens, Gloxinia (vars.), Stephanotis floribunda, Medinilla magnifica, and Strelitzia Reginae. *June:* Meyeria creta, M. erecta alba, Ixora coccinea, Jasminum dianthiflorum, Hoya bella, and Combretum purpureum. *July:* Cyrtoceras reflexum, Rondeletia speciosa major, Achimenes (vars.), Allamanda cathartica, A. Aubletii, Ixora aurantiaca, and Dipladenia crassifolia. *August:* Clerodendron fallax, C. Thomsonae, Echites splendens, Allamanda perfoliata, A. grandiflora, and A. Schottii. *September:* Ixora Rollinsonii, I. crocata, Torenia asiatica, Vinca rosea, V. ocellata, and Plumbago capensis. *October:* Impatiens Jerdoniae, Gesnera zebrina splendens, Beloperone violacea, Begonia fuchsoides acuminata, B. incarnata, and Poinsettia polcherrima. *November:* Billbergia thyrsoides, Torenia pulcherrima, Begonia splendens, Monochæton ensiferum, Ruellia macrophylla, and Begonia Prestonensis. *December:* Gesnera cinnabarina igea, G. reulgens, Stephanophyllum Baikiei, Kœleria lanata, Aphelandra aurantiaca, and Echeura Milneoni. We think "Flower Gardening for the Many" and "Florists' Flowers for the Many" would suit you. You can have them free by post from our office for ten postage stamps.

PELAGONIUMS FOR EXHIBITION IN JUNE (Constant Reader).—If, as you say, your plants are growing too fast, you should pinch out the points at once, tie out the shoots well, remove all superfluous foliage from their centres, and place in a light position close to the glass. Keep them cool—not higher than 40° at night—when it is necessary from frost to apply fire heat, and be very sparing with water at the root. Just give them enough to keep them from flagging. These conditions are the most likely to prevent a weak elongation of the tissues of the plants. If they get drawn up, know you will never make exhibition plants of them. As to the time of shifting them, that must depend on their being healthy and well rooted; and for showing in June they ought to be in that condition in the middle or end of January, and should then be shifted, but not into large pots. Eight-inch will be large enough. We prefer giving the last shift early in October. There is then far less chance of too gross a growth, if properly managed through the winter, than when shifted in spring. A rather strong loam, with a third well-rotted cowdung, and a little sand, will grow first-class Geraniums and weak guano water should be applied when the bloom-buds exhibit themselves, and left off when they begin to open.

NAMES OF PLANTS (Alfred).—1 and 2, not known; 3, Justicia speciosa; 4, Thyrsacanthus rutilans; 5, Salvia involucrata; 6, Pteris cretica. (H. Smith).—It is impossible to name such specimens with any degree of confidence. 1, is some Primula allied to P. auricula; 2, may perhaps be a Solдаго; 3, Stachys lanata; 4, Pulmonaria officinalis. (J. H. Bayly).—Asplenium lanceolatum. (J. M.).—Physianthus albens. (W. H.).—Your Mosses are—1, Riccia fluitans; 4, Hypnum undulatum; 2, Dicranum majus; 3, Hypnum proliferum. (Nomenclature).—Your plant is unrecognized by any of the authorities to whom we have shown it. It may be a Gnaphalium or it may be an Antennaria, but we cannot determine unless

we see some of its flowers. We think your plant is grown in gardens under the name of Gnaphalium lanatum. (J. McEay).—1, Laetrea tenericula; 2, Pieopeltis Ellardieri; 3, Adiantum pubescens. (A Constant Reader, Dublin).—Your trailing plant is Disandra prostrata.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

MR. HINDSON'S GAME FOWLS AT THE BIRMINGHAM SHOW.

As a matter of common justice I must call upon you to correct a statement which appeared in your paper of the 8th, impugning my character as Judge at the Birmingham Show.

For some years I have had Game fowls on a walk in the neighbourhood of Welshpool; and a short time since the person in charge desired permission to lend some of my birds to a Mr. Williams, a resident in or near Welshpool, a request with which I promptly and peremptorily declined to comply.

Imagine, then, my astonishment when, in my capacity of Judge at Birmingham, I discovered from peculiar marks (but not until after the prizes had been awarded) that the birds in question, exhibited by Mr. Williams, were my own property. I at once communicated the circumstance to my colleagues, and insisted that the birds be disqualified. This fact can be vouched for by the members of the Council. I am too well aware of the responsibility attached to my position, and place too high a value on my good name, to countenance any such imposition as that attempted; and if I can find means of punishing the principal in this disgraceful act, rely upon it he shall not escape scatheless. His situation in life should have made him above such a scandalous action. By inserting the above in your next you will oblige.—JOSEPH HINDSON, Barton House, Everton, near Liverpool.

Owing to absence from home, I have only just seen your Journal of December the 8th, in which are some remarks on certain Game prizes awarded at Birmingham to a Mr. Williams, of Welshpool, and which were subsequently cancelled. From information I possess, as Mr. Hindson's colleague, I am convinced that the imputation cast upon him in reference to these prizes is entirely unfounded, and had the real circumstances of the case been known to you, I believe the remarks which induce me to address you would not have appeared in your columns.

It is perfectly true that some of the Game fowls to which prizes were awarded belong to Mr. Hindson, but it is not true to assert or insinuate that they were sent to Birmingham with his knowledge or connivance. Of this no better proof is needed than the conduct of Mr. Hindson himself, for it was entirely upon information spontaneously furnished by him, and on his express demand, that the prizes were cancelled.

It will, perhaps, be asked, Why, then, were these prizes awarded? The answer is, that the facts which induced the Judges to disqualify the pens were not ascertained with sufficient certainty until a catalogue was referred to after the awards were closed, and the discovery made that the exhibitor was a person living at Welshpool, where Mr. Hindson's fowls are kept.

Apart from the reasons which induced us to disqualify the pens, I think there can be no question that they were entitled to the position in which they were placed; at any rate, on this point I willingly assume the entire responsibility.

What explanation Mr. Williams, the exhibitor, may be able to offer I have no means of knowing; but the conduct of Mr. Hindson convinced me that he was clear of all complicity in the matter, and that the presence of these fowls at Birmingham was an extreme annoyance to him. No one under the circumstances could have acted in a more open, frank, and honourable manner than he did, and this I am confident would be the testimony of every one with whom he communicated on the subject at Birmingham. I regret the necessity of asking you to publish this letter; but as Mr. Hindson's colleague, it would be ungenerous in me to

pass unnoticed an imputation on his character which I believe to be unmerited.—J. H. SMITH.

[Most readily do we insert the preceding communications, and hope they will prove satisfactory to our readers. We have no other object in vituperating apparent delinquencies than to secure a fair field to all competitors, nor do we censure before we have obtained what we consider reliable information. It is unfortunate that Mr. Hindson did not announce his discovery that the birds were his own until after one of the public had detected the fact; and there is one point on which neither Mr. Hindson nor Mr. Smith has afforded any information, and on which it is certainly desirable. It would be an answer to this question now before us:—"Who is Mr. Williams, of Spring Bank, near Welshpool? is he really an Esquire? I ask this because it was said to be the name of a man under Mr. Hindson's control."—Ems. J. or H.]

CAPTAIN HEATON AND THE BIRMINGHAM SHOW.

I HAVE read with some interest the remarks of your correspondents lately on "Poultry Shows and Judges." I am sorry that two or three cases have occurred recently, which show that those communications are not uncalled for. I allude to the recent occurrences at Birmingham and Leeds, which you have most judiciously treated, as I think, by making public the names of the offenders. With such cases as Mr. Hindson's and Mr. Frederick Hardy's, there cannot be any diversity of opinion.

In the matter of Captain Heaton there is not any suspicion of dishonesty; but there is a breach of rule and a want of fairness, of which he must allow me to say he has not in your last paper given a satisfactory account. His letter to "SMALL FRY" is most unsatisfactory. I have nothing to do with the question whether the birds were bred by himself or Mr. Kellaway; so that they were *bona fide* his own property (and of this I have not heard that there is any question), it matters little. Captain Heaton's answer to this is satisfactory enough. The question with which I wish to deal is, that of his unlawful and unfair admission to the Poultry Show at Birmingham, on Saturday, the 28th of November last.

I have before me the regulations and the programme of the Meeting, from which I quote the following:—

"17. No members of the Society, or of the Council, or other person will be admitted to Bingley Hall before the opening of the Exhibition, on Monday, November 30th, with the exception of those who are actually engaged in the arrangements within the building. Special cards of admission will be forwarded to the Judges to be used on Saturday, November 28th."

"The exhibitors and the public will be admitted to Bingley Hall to witness the judging of the cattle, sheep, pigs, roots, and corn (but not the poultry), on Saturday, November 28th, at 9 o'clock A.M., upon payment of 10s. each."

Now, these statements either mean what they put forth or they are worthless. If the former, Captain Heaton must know this meaning as well as I do, and, therefore, with knowledge he broke one of the regulations of the Show. If the latter, the sooner the Birmingham Show comes to an end the better for the unwary.

Who were the many others followed by Captain Heaton and Mr. Kellaway? If they were persons who, as in the case of these exhibitors, had not any business there, why did not Captain Heaton at once inform the Secretary or other chief in authority, and cause those persons to be removed? Captain Heaton must have known very well that the persons he followed were improperly admitted, and, therefore, he cannot escape the charge that he unfairly took advantage of an opportunity, a charge which in his case becomes serious as the winner of the two silver cups. I do not wish it to be understood for a moment that I question the justness of the award, or the worth of Captain Heaton's birds; but a man must accept the consequences of the situations in which he may place himself. The only way in which shows and exhibitors can thrive is by strict observance of rules. There cannot be any doubt but that Captain Heaton on his own showing broke a rule and took an unfair

advantage over more scrupulous exhibitors, which was most reprehensible, even though he did not use it for his own gain.

Captain Heaton wisely leaves the defence of the Birmingham Committee in their own hands; but it will want very ready hands indeed to afford the Committee a defence at all. The acts of their servants are their own. They are bound to offer some explanation, as what is miscalled "dignified silence" may be misconstrued. Rules must be rigidly kept by Committees and by exhibitors. It will not do to plead mistakes of this kind on the one hand, or following the example of many on the other. I hope that in all future shows any breach of rule by an exhibitor will be made a disqualification. In this I shall be supported by all honest men.

Captain Heaton will, I am sure, see with myself the importance of the subject, and the necessity of following it up closely by speaking strongly and to the point. He has made a mistake, and I have told him of it. Nevertheless, I much regret any annoyance which I may thereby have caused him.

As I am answering a communication which bears the name of Captain Heaton, I am bound to give my own, which may be found in the Birmingham catalogue.—GEORGE MANNING.

IN reply to Captain Heaton's statement in last week's JOURNAL OF HORTICULTURE, permit me first to thank that gentleman for the great anxiety he displays for my especial benefit, but at the same time to remind the Captain he has evaded the question at issue altogether—viz., by what means he and his friend gained admission on the Saturday to the poultry department of the Birmingham Exhibition, in direct defiance of printed regulations?

Certainly your numerous readers would be ill-prepared to receive the excuse, now urged by Capt. Heaton, that he was not aware that "any favour was granted to himself or Mr. Kellaway, we merely followed many others who entered before we did." It is beyond doubt that Capt. Heaton well knew he was thus breaking the Birmingham rules, and the excuse that he did only as others did before him is hardly what might be fairly anticipated from a government officer, and one so well acquainted with military discipline as is Capt. Heaton. It nevertheless reveals a recognition that "harmless excuses are better than none," whilst it does not even attempt either to explain how the admission was obtained, or give any reason why the rules were then so flagrantly violated in favour of those exhibitors who chose to pay the high admission fee of ten shillings. There are those individuals who curiously enough suppose that all such admission money was not thrown away; but certainly the provisos of the printed rule expressly debarred even those who actually paid the ten shillings from viewing the poultry on the Saturday; yet it is now openly admitted that Capt. Heaton, Mr. Kellaway and many others, enjoyed this privilege unmolested by any one. Should such things be?

It is only by strict equality of privileges to every exhibitor, that even the Birmingham Show can hope to maintain its past position for integrity of purpose. No rule can be honest if not sound to the core—in short, that does not admit, or exclude, all competitors alike, without favour or affection.

As a conclusion Capt. Heaton hands over all further inquiry into this now unquestionable dereliction of rules to the better hands of the Birmingham Committee. Do let us hope that clean hands, therefore, are the order of the day. Still exhibitors have but little reason for hope in the direction now named, for rumour is everywhere rife that "the matter is to be best met by allowing it to sleep; and then all recollection of it will be blown over before the time arrives for another year's meeting." If this rumour is correct, and really present circumstances look very much like it, pray let the bed be made up for two—viz., the admission of rich exhibitors without right, to the prejudice of the less pecuniarily fortunate; and the unprecedented eccentricities of the Game-judging at Birmingham, in 1863; and then let both (if they can) sleep comfortably together, for they are fitting bedfellows; and possibly their's will be roscate dreams, for

Be it said, without shocking them,
They lie snoring asleep, whilst the Council are rocking them.
—SMALL FRY.

THE NEWPORT, MONMOUTH, POULTRY SHOW.

It really appears as though the multiplicity of poultry shows just now taking place, so far from detracting, only added to the public interest of poultry-culture. Good as have been the previous meetings at Newport, it is unquestionable, even at the most furtive glance, that the poultry this year exhibited far surpasses all former attempts of the kind in South Wales.

A perusal of the prize list will prove that scarcely a single breeder of well-known celebrity was unrepresented at Newport. True it is, the Viscountess Holmesdale took a full "lion's share" of the distinctions—to wit, three first prizes, four second, a third, and three high commendations; still, after so complete a sweep, there will be found on consulting the awards that this lady's triumph was by no means achieved without the most severe competition. The whole classes of *Grey Dorkings* and *Spanish*, as left after the selection of the prize pens, would have been considered beyond an average amount of merit at most poultry shows. This fact speaks volumes in favour of the Newport Show, when it is borne in mind that fifteen pens obtained honourable distinction in these two classes only. The *Game* classes were in no wise inferior; and with such an amount of entries as took place this year, the Managers of this Show will most probably increase the number of Game classes to meet the future necessities of the Newport Exhibition, two classes only being a great restriction to varieties so diversified as the Game breeds. The *Polands* and *Hamburghs* were better by far than we anticipated; and the *Cochins* and *Brahmas* were also deserving of especial mention.

The *Geese* and *Turkeys* were first-rate, indeed we rarely see better; and the *Duck* classes were well filled with the best of birds.

The collection of *Pigeons* was limited to only forty-three pens, but contained capital specimens, and among them many new varieties.

The Committee were most assiduous in adding all in their power to the comforts of both the poultry and the visitors, and as the weather was good, all things went off prosperously. The whole Show consisted of 371 pens.

SPANISH.—First and Second, Viscountess Holmesdale, Linton Park, Kent. Third, C. Clayford, Sunnyside, Northampton. Highly Commended, H. Lane, Bristol; J. Stevens, Walsall. Commended, J. Stevens, Walsall; Mrs. Blay, Worcester; J. K. Fowler, Aylesbury.

DORKINGS (Coloured).—First and Second, Viscountess Holmesdale, Linton Park. Third, Mrs. Pettat, Basingstoke. Highly Commended, J. Logan, Newport. Commended, Capt. F. T. Parker, Monmouth; J. K. Fowler, Aylesbury; Miss J. Milward, Newton St. Loe, Bristol.

GAME (Any variety except White or Piles).—First, H. Adams, Beverley, Yorkshire. Second, M. Billing, jun., Birmingham. Third, J. H. Braiteridge, Bristol. Highly Commended, J. Heath, Nantwich, Cheshire; J. B. Chune, Coalbrookdale, Shropshire; C. Bulpin, River Side, Bridgewater; J. Llewellyn, Caerphilly, Glamorgan. Commended, A. B. Dyas, Madeley, Shropshire; M. Billing, jun., Birmingham.

GAME (White or Piles).—First, M. Billing, jun., Birmingham. Second, H. Adams, Beverley, Yorkshire. Third, J. Llewellyn, Caerphilly, Glamorgan.

COCHIN-CHINA (Coloured).—First, W. Bradley, Diglis Locks, Worcester. Second, J. K. Fowler, Aylesbury. Third, Viscountess Holmesdale, Linton Park. Highly Commended, Viscountess Holmesdale, Linton Park; R. H. Nicholas, Malpas, Newport. Commended, J. Stevens, Walsall; R. H. Nicholas, Malpas, Newport; H. Calhoun, Great Malvern; J. Carr, Hafod, Swansea.

BRAMA POOTRA.—First and Second, J. Hinton, Hinton, Bath. Highly Commended, J. K. Fowler, Aylesbury.

HAMBURGHS (Gold or Silver-pencilled).—First, Viscountess Holmesdale, Linton Park. Second, J. Holland, Worcester. Third, Miss C. Purnell, Pont-Canna, Cardiff. Highly Commended, Miss C. Purnell, Pont-Canna, Cardiff; R. H. Nicholas, Malpas, Newport; Viscountess Holmesdale, Linton Park. Commended, J. B. Chune, Coalbrookdale, Shropshire; T. Fletcher, Great Malvern; C. H. Wakefield, Malvern Wells.

HAMBURGHS (Gold or Silver-spangled).—First, Viscountess Holmesdale, Linton Park. Second, T. Davies, Newport. Third, G. Brook, Baddingstoke. Highly Commended, M. Billing, jun., Birmingham; Mrs. Pettat, Basingstoke. Commended, W. Lewis, Pilgwenilly, Newport; T. Davies, Newport; J. B. Chune, Coalbrookdale.

POLANDS (Black with White Crests).—Prize, R. H. Nicholas, Malpas, Newport.

POLANDS (Golden or Silver).—First, J. Heath, Nantwich, Cheshire. Second, R. H. Nicholas, Malpas, Newport. Highly Commended, Mrs. Blay, Worcester. Commended, T. Fletcher, Great Malvern; Mrs. Pettat, Basingstoke.

BANTAMS (Game).—First and Second, T. Davies, Newport. Commended, M. Billing, jun., Birmingham; J. K. Fowler, Aylesbury.

BANTAMS (Any other variety).—First, R. H. Nicholas, Malpas, Newport. Second, Viscountess Holmesdale. Third, E. Cambridge. Highly Commended, W. Bowly, Cirencester; F. H. Phillips, Chippingham, Wits; G. Williamson, Nantwich, Cheshire; Miss G. Everett, Gibraltar Cottage, Monmouth; J. Maund Duffry Maw, Abergavenny. Commended, E. Jones.

ANY OTHER DISTINCT BREED.—First, R. H. Nicholas, Malpas, Newport (Black Hamburghs). Second, Viscountess Holmesdale, Linton Park (White

Cochins). Third, T. Ashton, Tamworth (White Dorkings). Highly Commended, R. H. Nicholas, Malpas, Newport (Chinese Silkies, Cuckoo Maracas, and Black Hamburghs); F. P. Cother, Salisbury (Pheasant Malays); J. J. Fox, Devizes, Wits (Malays); J. Carr, Hafod, Swansea (White Cochins); G. Williamson, Nantwich (White Cochins); W. Bowly, Cirencester (Silkies); Master C. A. Ballance, Taunton (Malays). Commended, W. Powell, The Gaer, Newport (White Dorkings); Capt. F. T. Parker, Rockfield, Monmouth (White Cochins).

GUINEA FOWLS.—Prize, Sir G. F. K. Walker, Bart., Castletown, Cardiff. Commended, R. H. Nicholas, Malpas, Newport.

DUCKS (Aylesbury).—First, Second, and Third, J. K. Fowler, Aylesbury. Highly Commended, J. Logan, Newport. Commended, E. Shaw, Oswestry, Salop; A. Cuthbertson, Llangibby, Newport.

DUCKS (Rouen).—First, J. K. Fowler, Aylesbury. Second, H. J. Evans, Cardiff. Third, C. Lyne, Brynffrid, Newport. Highly Commended, W. Powell, The Gaer, Newport; J. H. Brackenridge, Chew Magna, Bristol. Commended, A. Cuthbertson, Monmouth.

GESE.—First and Second, J. K. Fowler, Aylesbury. Third, A. Cuthbertson, Monmouth. Highly Commended, J. Logan, Newport. Commended, R. Tees, Abergavenny.

TURKEYS.—First, Miss J. Milward, Newton St. Loe, Bristol. Second, Mrs. Horlock, East Vaga, Chepstow. Third, Mrs. Lewis, Dannel Hill, Chepstow. Highly Commended, H. J. Evans, Cardiff. Commended, J. K. Fowler, Aylesbury; Mrs. Horlock, East Vaga, Chepstow.

SWEETSTAKES FOR COCKS.

SPANISH.—First, H. Lane, Bristol. Second, Viscountess Holmesdale, Linton Park. Highly Commended, Viscountess Holmesdale, Linton Park. Commended, T. Davies, Newport; E. Newman, Newport.

DORKING.—First, Viscountess Holmesdale, Linton Park. Second, E. Shaw, Oswestry, Salop. Highly Commended, Captain F. T. Parker, Rockfield, Monmouth; W. Bowly, Cirencester. Commended, Viscountess Holmesdale, Linton Park.

GAME.—First, J. B. Chune, Coalbrookdale, Shropshire. Second, R. H. Nicholas, Malpas, Newport. Highly Commended, A. B. Dyas, Madeley, Shropshire.

COCHIN-CHINA.—Prize, Viscountess Holmesdale, Linton Park. Highly Commended, J. Carr, Hafod, Swansea.

GAME BANTAM.—Prize, Miss C. Purnell, Pont-Canna, Cardiff. Highly Commended, T. Davies, Newport.

ANY OTHER VARIETY.—First, W. Lewis, Pilgwenilly. Second, J. Carr, Hafod, Swansea. Highly Commended, Miss C. Purnell, Pont-Canna, Cardiff; T. Davies, Newport; Viscountess Holmesdale, Linton Park.

COTTAGER'S PRIZES.

FOWLS.—First, Second, and Third, W. Jenkins, Malpas, Newport. Fourth, Mrs. E. Ford, Malpas, Newport. Highly Commended, G. F. Winnill, Newport.

DUCKS.—First, E. Hill, Malpas, Newport. Second, D. Hickey, Llanwera, Newport. Third, W. Pilling, Malpas, Newport. Fourth, G. Koundy, Malpas, Newport.

PIGEONS.—*Carriers.*—First, J. W. Edge, Aston, Birmingham. Second, C. Bulpin, River Side, Bridgewater. Commended, C. D. Phillips, Newport. *Pouters.*—First, C. Bulpin, Bridgewater. Second, M. E. Jobling, Barras Bridge, Newcastle-on-Tyne. Commended, M. E. Jobling, Newcastle-on-Tyne. *Tumblers.*—First, H. Yardley, Birmingham. Second, J. W. Edge, Aston, Birmingham. *Fantails.*—First, J. W. Edge, Aston, Birmingham. Second, T. Roe, Newport. Highly Commended, A. Heath, Calne, Wilts. Commended, Miss J. Milward, Newton St. Loe, Bristol. *Any other variety.*—First, H. Yardley, Birmingham. Second, M. E. Jobling, Newcastle-on-Tyne. Third, A. Heath, Calne. Highly Commended, C. Bulpin, Bridgewater.

Edward Hewitt, Esq., of Sparkbrook, Birmingham, judged the poultry; and Dr. Cottle, of Cheltenham, awarded the Pigeon prizes; both these gentlemen expressing themselves gratified at the high quality of the birds exhibited.

ROYAL DUBLIN SOCIETY'S POULTRY SHOW.

DECEMBER 15TH.

The following were the awards:—

BRAMA POOTRA.—Prize, Mrs. F. Blair, Balthayock Castle, Inchmarine, Inchture. *Chickens.*—First and Second, Mrs. F. Blair.

DORKING.—First and Second, Mrs. F. Blair, Balthayock Castle. Highly Commended, R. P. Williams, Hollybrook; A. Warburton, Kill, Naas. Commended, Mrs. F. Blair, *Chickens.*—First, G. Langtry, Malahide. Second, R. P. Williams. Highly Commended, Lord J. Butler, Drumcondra Castle; J. J. Lafarelle, Stillorgan; J. Hutchinson, Christ-Church Place. Commended, R. P. Williams; R. W. Boyle, Dundrum.

SPANISH.—First, R. W. Boyle, Dundrum. Second, Miss E. de C. Drevar, Rose Hill, Blackrock. Commended, R. P. Williams, Hollybrook, Clontarf. *Chickens.*—First, Second, and Commended, R. W. Boyle.

COCHIN-CHINA.—First and second, Mrs. F. Blair, Balthayock Castle. Highly Commended, R. W. Boyle, Dundrum. *Chickens.*—First, R. P. Williams, Hollybrook. Second, Mrs. F. Blair. Highly Commended, G. Langtry, Malahide; R. P. Williams; F. W. Zarhoist, Belville, Donnybrook.

GAME.—First, G. Langtry, Malahide. Second, T. H. Howland, Chester. Commended, R. W. Boyle, Dundrum. *Chickens.*—Prize, C. H. Peacocke, Carrig-na-greine, Dalkey.

HAMBURGH (Spangled).—First and Second, R. P. Williams, Hollybrook, Clontarf.

WHITE-CRESTED BLACK FOWL.—First and Second, Miss E. de C. Drevar, Rose Hill, Blackrock. *Chickens.*—First and Second, Mrs. E. de C. Drevar.

ANY OTHER DISTINCT BREED.—First and Second, Mrs. F. Blair, Balthayock Castle (Crève Cœur and La Fleche). *TURKEYS.*—First, Mrs. F. Blair, Balthayock Castle. Second, Captain C. Hamilton, Kildare. Commended, G. Langtry, Malahide. *Poult.*—First, R. W. Boyle, Dundrum. Second, Mrs. F. Blair. Commended, Captain C.

Hamilton. *Ten Poults*.—First, Capt. C. Hamilton. Second, J. Lentagne, Tallaght. Commended, J. Hyland, Dublin.

Geese.—First, R. W. Boyle, Dondrum. Second, Mrs. F. Blair, Balthagoek Castle. Highly Commended, C. H. Peacocke, Carrig-na-greine, Dalkey; G. Langtry, Malahide. *Goslings*.—First, Mrs. Plunne, Stacklawn, Navan. Second, Mrs. F. Blair.

Ducks.—First, R. P. Willdens, Hollybrook, (Rineen). Second, R. W. Boyle, Dondrum (Aylesbury). Highly Commended, C. H. Peacocke, Carrig-na-greine, Dalkey (East Indian). *Ducklings*.—Prize, Mrs. F. Blair, Balthagoek Castle (Rouen).

BEST LOT OF POULTRY EXHIBITED BY A PUBLIC INSTITUTION.—First and Second, Mrs. McDonnell (for the Commissioners of National Education), Glasnevin, Dublin.

RESULTS OF THE BIRMINGHAM POULTRY SHOW.

THIS important Exhibition was brought to a successful termination on the 3rd instant, and it will be seen on reference to the subjoined comparative statement that the admissions were more numerous than on any former occasion; and although, owing doubtless to the unfavourable weather, the money paid at the doors was smaller in amount than in 1862, the deficiency is more than compensated by subscriptions, &c., and the sale of four thousand additional tickets, at 6d. each, for the working classes.

Pens over 1862... 70 Proceeds over 1862... £312 17 11

The sums paid in various instances show that the interest in poultry is not diminishing; and to the foregoing particulars we may add that Captain Heaton's two silver cups pens of Cochins sold for £25 each; that the same exhibitor's second-prize adult Cochins sold for £20; Mr. Henry Lane's first-prize Spanish pullets for £20; Mr. Chase's first-prize adult White Cochins for £15 15s.; Mr. Fowler's third-prize Aylesbury Ducks for £12 12s.; and the following pens for £10 10s. each:—Captain Hornby's Dorking chickens, No. 89; Mr. Dolby's Dorking pullets, No. 164; Mrs. Ferguson Blair's first-prize Brahma Pootra chickens; Mr. Wood's silver cup Game chickens; Mr. Garlick's first-prize Game; Mr. Richard White's single Cochin cock; Messrs. Siddons and Sons' first-prize Black Carrier Pigeon hen. Mr. Bishop's first-prize Cochin pullets went for £10; and Mr. Stubbs's second-prize Game chickens for £10.

Immediately upon the close of the Exhibition preparations were commenced for the transmission of the poultry to their respective owners, and the laborious work was admirably carried out under the energetic superintendence of Mr. Mapplebeck. Those birds which had to travel the greatest distance were forwarded by early railway passenger trains on Friday morning, so as to reach their destination in the course of the day, and those belonging to local exhibitors were ready

for delivery to applicants by twelve o'clock. The general oversight and feeding of the poultry was entrusted to Mr. Powke, for many years steward and bailiff to the late Hon. W. Vernon, of Hagley Hall, near Rugeley; and the fidelity with which his functions were performed may be inferred from the fact that not a single bird of any kind died from disease or accident in Hagley Hall.

DARLINGTON EXHIBITION OF POULTRY.

THE following are the awards made in the Pigeon classes at the above Show:—

CARRIER (Any colour). Cock.—First and Cup, J. Firth, Dewsbury. Second, E. Vaux, Sunderland. Commended, J. W. Wooley, Saltergate Hall; F. Elze, Bayswater. *Hen*.—First, F. Elze. Second, G. R. Potts, Sunderland. Commended, J. Firth.

POWTER (Any colour). Cock.—First, R. Fulton, Dufford. Second, W. Taylor, Sheffield. Commended, C. J. Samuels, Longsight. *Hen*.—First, R. Fulton. Second, E. Brown, Sheffield.

TUMBLERS (Almond).—First, F. Elze, Bayswater. Second, G. R. Potts, Sunderland.

TUMBLERS (Any other variety).—First, J. W. Edge, Aston, Birmingham. Second, R. Fawdon, Gateshead.

FAN-TAILS.—First, H. Yardley, Birmingham. Second, T. C. Taylor, Middlesborough.

TRUMPETED.—First, J. J. Wilson, Darlington. Second, Master J. Charlton, Munningham.

BARRAS.—First, H. Yardley, Birmingham. Second, Master J. Charlton, Munningham.

JACOBS.—First, H. Yardley, Birmingham. Second, Master J. Charlton, Munningham. Commended, J. W. Edge, Birmingham.

TURKISH.—First, J. Taylor, Euton. Second, R. Thompson, Moresdale Hall.

OWIS.—First, M. E. Jobling, Luras Bridge. Second, J. Bell, Newcastle-on-Tyne.

ANY OTHER NEW OR DISTINCT VARIETY.—First, C. J. Samuels, Longsight (Dragoons). Second, H. Yardley, Birmingham (Satinettes). Third, M. E. Jobling, Barras Bridge (Blue Brunswicks).

BEES DYING OF DYSENTERY.

WILL Mr. Woodbury kindly come to the help of a sufferer, and direct him as to the cause and cure of a disease, which, though not so extensive in its operations, is as deadly in its results as foul brood?

Towards the end of July a swarm was lodged in an empty hive; and as it was impossible for it so late in the season to obtain out of doors a sufficiency of food for winter, it was liberally supplied, at intervals, with sugar till about the end of September, when, from the number of bees in the hive, and the quantity of food stored up, I hoped with a little care to have rendered them secure against frost and famine. But I am doomed to disappointment. During October and November the bees have died off at the rate of one or two hundred per day; and now what was a goodly swarm two months ago can be contained in a breakfast-cup. The bees lie strewn on the floor-board and around the hive. Their flaccid abdomens are somewhat swollen, and when torn up a darkish fetid fluid is emitted. Besides, there are in the hive a very few cells containing either chilled or foul brood. How is the malady to be arrested? Will it infest the neighbouring hives, and should the sugar-filled combs be at once "consigned to the melting-pot?"—ONE IN PERPLEXITY.

Of late years I have unfortunately been but too familiar with the kind of dysentery described by my esteemed correspondent. Although not able to speak positively as to the cause of the disease, I have a very strong impression that it is often due to the use of artificial food, and also that it frequently arises from the presence of internal moisture. On this account bees in wooden boxes appear more liable to its attacks than those domiciled in straw hives, and it is for this reason that I have recently been led to prefer straw to wood in the construction of bee-hives.

When a colony is attacked at this season, I believe there is little chance of cure. After trying every remedy I could hear or think of, I have found the best palliatives to be the immediate removal of the bees and combs into a clean and dry straw hive, with ample ventilation on the top, and removing all dead bees promptly, by giving them a clean floor-board daily. All attempts at feeding should be abandoned, and the bees disturbed as little as possible. When spring is sufficiently advanced, I have, with the aid of frame-

* This can only be done when either bar or frame-hives are used.

hives, effected a radical cure in this manner.—During the middle of a fine, warm day look over the combs one by one until the queen is found, and then imprison her in a queen-cage. Next carry the hive to a short distance, and stand it on the ground, putting an empty hive in its place. This done, spread a cloth close to the removed hive, and, lifting out one of the combs, brush every bee from it on to the cloth, and then put the comb into the hitherto empty hive. Repeat this process with the other combs until the hive be empty, when stragglers should be brushed out and the hive itself removed, not to be again used until it has been thoroughly washed and purified. Finish the operation by putting the crown-board on the new hive, and introducing the queen at the top. Any very young and immature bees may be picked up and conveyed to their new domicile, but no adult bee should be suffered to enter it that cannot rise from the ground and reach the alighting-board by the use of its wings alone.

As I have found this process effectual when every other means have failed, it would appear that the disease is infectious within the limits of the same habitation, although I have never found it spread like foul brood from one stock to another. By shifting the colony into a pure hive into which healthy bees alone—i.e., those able to fly—are suffered to enter, they are at once removed from their diseased brethren, and the plague is stayed.

This disease would seem to be wholly distinct from foul brood, although I have seen both co-exist in the same hive. As, therefore, there are a few cells containing either chilled or foul brood, it certainly would be the safest plan to consign the whole of the combs to the melting-pot.—A DEVONSHIRE BEE-KEEPER.]

FOUL BROOD.

WHEN I sent my last communication on this subject (page 181), I had not the slightest intention or desire to give any offence to those who held opposite opinions to my own; neither could I see any good reason for the style adopted by some towards Mr. Woodbury, more especially when he so honourably came forward, and publicly announced his failures as well as his success. I also thought it a pity that those who had adopted the "tilting" style of argument should be allowed to have it all their own way, and that they ought to be able to take a little of the "poking" themselves. If I have given offence to any one in the remarks I then or now make, I am truly sorry for it; all I desired and desire is to arrive at the truth, so as to enable us to get rid of foul brood from whatever cause it originate; and if each would merely detail his own experience and observations the truth will be elicited, and good will follow. Without saying more on that "foul" subject, I will state what has taken place in my neighbour's apiary as well as my own since our bees came home from the heather.

When my neighbour's bees came home he found all the old stocks diseased, and out of five swarms of this year one was diseased. The swarm had been put into an old hive, which at one time had diseased brood, but the combs had all been removed. In the month of June he cut out all the foul comb from one of his own hives and also from one belonging to a neighbour, but without any good effect, as both were diseased again in September.

Since they came home he has put down all the old stocks as incurable, and has kept the bees, uniting three stocks into one, and put them into a hive full of empty comb which I gave him, and which had been robbed by its neighbours at the hills, but was free of diseased brood. Previous to putting the bees into the clean hive he put them into an eke with some clean comb, and fed them there for ten days with Australian honey and sugar that they might cleanse themselves, and take none of the disease with them.

The feeding caused the queen to commence egg-laying in six days, although she had ceased doing so seven weeks before. He then put them into the hive which I gave him, and supplied them with 23 lbs. of honey and sugar in ten days. The result is that the hive has increased 7 lbs. more than the weight of honey and sugar he gave them, owing to the young brood which she is now rearing. From the lateness of the season he does not expect success in this experiment, still something will be learned from it I expect. He is

careful in keeping this hive well covered, and will use every possible means to protect from cold.

I gave him a swarm of driven bees from one which I had to destroy, where there had been no disease. He is feeding them with honey entirely from diseased hives, which will enable him to see if it has any effect in inducing the disease. He has failed entirely in effecting a cure by cutting out all the diseased comb, as Mr. Woodbury has done, although he has done it with every care.

When I stated in my last communication that I never had seen the disease among any of my hives, I did not expect that I should have it so soon; as, I am sorry to say it has come into one of mine, in a neighbour's hive, and I destroyed it at once, and the disease does not exist in any of the others.

We find in this part of the country that there is more foul brood than many are aware of. A person not far from this told me that he had never seen it in his hives, but when he took a piece of the diseased comb home to his wife, she soon told him that she had seen it often; and when he examined them he found one of them very badly affected. This is a person who, I expected, would have observed it at once, as he has had great experience in bees, and treats them just in the usual way.

I may just state that the queen I had from Mr. Woodbury, and noticed in page 303, is still laying eggs. On November 3rd I inserted a thermometer through the straw at the top of a Woodbury straw hive, between the bars, and was astonished to find that it stood at 85°, and has done so night and day ever since, falling only 2° when we had 10° of frost. It is surprising to me how they can keep up such a heat, as I am not feeding at all. I have other two queens egg-laying at present (October 18th), but would rather that they would stop; but it will enable us to see if it is really the cold that causes the disease. Whatever may occur I will not fail in letting it be known to the apiarian readers of this Journal.

The above was written more than six weeks ago, but seeing the spirit which some of the writers on foul brood were manifesting on that subject, I delayed sending it week after week, thinking that, as the cold weather came on, like the bees they would become quiet. But I regret, as many others do, that hands have not been shaken over this controversy before now, and I for one will not add another word on it, unless to detail what takes place here, either in my neighbour's or my own apiary. I have no motive whatever but to ascertain the truth, and it matters not to me who is right or who is wrong.

If foul brood is caused by cold so much the better, we shall be able to prevent it. If a disease, then let us try and find out the cause, that we may the more readily find a remedy.

On the 23rd of November, I found all the young bees were hatched, not one remained in the cells, and no new-laid eggs, which I was pleased to see. Temperature in the hive 85°, and on December 6th it was 65°, while the out-door temperature was in both cases the same.—ALEX. SHEARER.

BEEES AT THE MOORS AND IN SOUTH LANCASHIRE.

BEEES have done very badly on the moors in Lancashire, Yorkshire, and Derbyshire. The hives that I sent to the moors lost on an average 42 ozs. per hive, and only one hive gained 17 ozs. Although the weather was so very bad, the bees did much better than those left at home, as they consumed on an average nearly double the weight during the same time. It rained in August on twenty-two days, the amount being 3.77 inches, and in September it rained on twenty-two days, the amount being 5.02 inches. The total amount of rain that fell in February, March, April, May, and July was only 5.79 inches, so that in September alone there fell within about three-quarters of an inch as much rain as in the five months mentioned. It is astonishing that the bees did so well with this enormous amount of rain, and I can only account for it by the very large quantity of bloom on the heather. I think I never saw so much before, and if the weather had been favourable the amount of honey collected would have been unprecedented.

During the summer I took from four of my strong stocks nearly 100 lbs. of very beautiful honeycomb; so that on the whole I am very well satisfied and thankful for the bountiful season of 1863. I have now one of the finest apiaries in this country, or, perhaps, in England, as my stocks are in my improved bar-frame hives, strong and with plenty of honey.

Your correspondent, "A SOUTH LANCASHIRE BEE-KEEPER," in his letter, which appeared in THE JOURNAL OF HORTICULTURE of the 3rd ult., seems to have been very unfortunate with his bees this year, as it appears that he has only taken about 5 lbs. of honeycomb, and has finished the season with only two stocks, the same with which he commenced the year, and is in the unenviable position of having his Ligurian stock requiring food to carry it over the winter, and it refuses to carry liquid food into the hive.

You advise him to try the bottle-feeder, but I believe he will find that during the cold weather the bees will scarcely touch it; and as he neglected feeding them up to the required weight in the beginning of October, his only chance now will be to remove the cover of the hive on one side, and put between each of the combs some sticks of barley-sugar. A stock of bees that I purchased on October 12th carried into the hive 8 lbs. of loaf-sugar made into 12 lbs. of liquid food in thirty-six hours. If "A SOUTH LANCASHIRE BEE-KEEPER" will write to me I will try to assist him to make his bees more profitable another year.—WM. CARR, Clayton Bridge, Newton Heath, near Manchester.

DRIVING BEES.

WHEN a person becomes master of any branch of science, it appears so easy that he is very apt to laugh at the novice on seeing him fail in accomplishing some experiment in that branch. This is unjust, but it is quite excusable when we know that the novice is self-conceited and wedded to his own preconceived notions, and will not take advice. Now, I see plainly that it is the case with a great number of your correspondents to whom advice has been given. They are so prejudiced for their own way that they seldom succeed in an operation, even after great pains have been taken to explain that which has baffled them so much. Now, it appears that a great number of bee-keepers fail in driving their bees, although it is a very simple process; and even after the very able and well-advised letter of "A DEVONSHIRE BEE-KEEPER," we yet hear of failures, all arising from the want of a little perseverance in following his directions. Although he has given those directions so plainly, yet there is a point or two which, perhaps, he has thought too simple to mention, and yet they are of great importance to enable the novice to succeed in driving.

The first point is to take care not to enrage a single bee till the hive has been inverted, because it is only at the lifting of the hive that the bees get enraged, and they seldom use their stings after the hive has had a smart rap or two if dealt rightly with at first.

The second point is to dislodge the bees when they appear to remain firm to their hive. This is the trying point to the novice, and hence so many failures; yet the plan to dislodge easily is to remove the empty hive, and in the greatest cluster of the bees to give them a smart whiff or two with the breath or with a pair of kitchen bellows, which will at once set them running.—A LANARKSHIRE BEE-KEEPER.

BEES AND HONEY OF GREECE.—The honeys of Hybla and Hymettus are at this day almost as celebrated as they were in the time of the classical Greek poets; the honeys of Cerigo, of Zante, and many other places, continental and insular, are all fine, and each has its admirers. The honey of Leucadia is, perhaps, almost as good as any, and the descendants of the bees that fed Ulysses deserve some consideration. I was interested, then, in the little bee garden on the site of the old city of Leucas. It was a rocky, barren-looking spot, and did not at first sight seem very promising, for the whole ground for a great distance around looks naked and without vegetation. But it is not really so. Every little crevice or interval between two stones, whether large or small, and not a few holes made by vegetation in the solid rock itself, contain some little flowering plant especially patronised by the honey bee. Rosemary and sage abound. I

was not much surprised, therefore, to see the bees, but the hives rather puzzled me at first. They consist of small oblong boxes placed on end on a low stone, each box being covered by two or three tiles, evidently to keep off the heat of the sun in summer. Two round holes, each about half an inch in diameter, sufficed for the bees to enter and emerge, and it did not seem to matter much where these holes were pierced. The boxes were constructed in the roughest manner, and seemed to have two or three cross sticks within them. They were placed not 2 feet apart, and each box was about 20 inches high, and 9 inches square in section. The bees were exceedingly busy and perfectly good-tempered.—(Aristotle's *Ionian Islands* in 1863.)

POLLEN-GATHERING.—I was greatly surprised yesterday (December 13th), to see my bees taking in pollen, obtained, I presume, either from some late-blooming ivy or laurustinus, which is in full bloom here (East Cornwall). The 26th of November, the same day on which your correspondent at Crom Castle observed pollen going into his hives, was the day which I had noted down as the last of the pollen-gathering ones for this season.—J. L.

MRS. GARNHAM'S "LADY'S ASSISTANT" is testified by many to be a most useful addition to the work-table. One lady says, "It is a great acquisition to those whose failure of sight prevents their effecting all they desire in finer sorts of needlework, taking up stitches in knitting, &c." Those who do not wear glasses while sewing, yet cannot thread their needles, will find the "Lady's Assistant" invaluable. It concentrates the light most efficiently. Mrs. Garnham is the daughter of the late Mr. Payne, who was our apian authority formerly, and she is now residing in Churchgate Street, Bury St. Edmunds, and sells this useful Assistant.

OUR LETTER BOX.

SUBSTITUTE FOR HOLLY BERRIES (J. M.).—We know of no mode of dyeing peas so as to make up for a deficiency of holly berries in winter decorations; but we should well some red sealing-wax and dip the peas in that.

DYEING MOSS (Moss).—To dye it green, dissolve as much verdigris in the distilled vinegar as possible. To dye it blue, dissolve in a glass tumbler one drachm of powdered indigo in one ounce of sulphuric acid, stir it with the stalk of a clean tobacco-pipe or a glass rod, and, after standing twelve hours, add as much water as will reduce it to the desired tint.

IMPROVING DORKINGS (P. B.).—We think your purpose will be more easily answered with eggs than with a hen, as the change will be effected in less time and more completely. Eggs travel by railway without injury.

FATTENING DUCKS FOR EXHIBITION (L. X. Z.).—All poultry should be shut up when fattening. Exercise is not favourable to the formation of fat. They should not only be shut up, but should have only room sufficient to turn and move.

EGG-EATING HENS (A Victim).—It is believed that hens first eat their eggs for the sake of their shells, in order to form the shells of those that have to be laid. This may be remedied by laying bricklayers' rubbish about their haunts. There are two ways of preventing and perhaps of curing them of the cannibal habit. One is to watch them when they are on the nest, and to drive them from it the moment they have laid. The other is to put very hard composition eggs in the nests. The hens peck at these with no other result than to make their beaks sore, and they get tired of the practice.

BREEDING DORKINGS FOR EXHIBITION (Senex Gallus).—It is considered almost impossible to breed a prize pen from parents taken from the same yard. Those who exhibit the best birds generally choose a cock from one yard and the pullets from another. This is the case in nearly all breeds. Large birds are bred from very large hens put to middling-sized cocks. Your stock bird is heavy enough at 7½ lbs. Ten and a half pounds would be a bad stock-getter. We relieve the Judges do not weigh Dorkings as a rule. They do sometimes, but prizes are mostly awarded by handling. We do not know the weight of the prize birds at Birmingham.

LONDON MARKETS.—DECEMBER 21.

POULTRY.

It is usual for prices to improve a little on the approach of Christmas, and the present year is not an exception. At the time of our going to press the 25th was not near enough for us to say what the market was, but the customary rise was taking place.

From observations taken near London during the last thirty-six years, the average day temperature of the week is 43.3°, and its night temperature 32.0°. The greatest heat was 57°, on the 3rd, 1860; and the lowest cold, 4°, on the 2nd, 1854. The greatest fall of rain was 0.86 inch.

RENEWING VINES WITHOUT LOSING A CROP OF GRAPES.

FROM the nature of the many inquiries which have recently been made by amateurs and others who have not had much experience in renewing Vines and Vine-borders, a few remarks on the subject may

at present be of service. In the case of those whose supply of Grapes depends on one or at most two vineries this operation, even when in a high degree necessary, is delayed in many cases from one season to another, because the owners cannot make up their minds to the dreaded loss of a year's crop, scanty and inferior though that crop might be. Apart from this consideration I would be the last to recommend the destruction of a set of Vines however old, if all that is needed to restore them to vigorous fruitfulness be to lift the roots, and give them a new and proper border, as recently described in these pages. But there are many cases where, through a wrong start and after-mismanagement, Vines are reduced to such a state that no hope could possibly be entertained of its being more desirable to go on with

them than to plant afresh. To say the least of it, a crop the season after lifting and replanting them could not be reasonably expected; for I have seen Vines in wet pasty borders with nothing in the way of healthy fibres but a lot of bare black roots, and when in that condition it would require dexterous management indeed to make the Vines bear fruit the same season. True, the loss of one season's crop under such conditions may not be worthy of consideration when weighed against the good results which might eventually follow, yet, in many cases, the fear of this loss is found sufficient to prevent the Vines being meddled with at all.

The question which at once presents itself in such cases is, Can the loss of a crop, even for one season, not be avoided by any other method or scheme that can be adopted? There are many who are perfectly able from their own experience to answer that any such loss is not at all unavoidable, and who would be able to describe how the improvements necessary can be well carried out, not only without causing the loss of a crop,

but, on the contrary, so as to be productive of a positive gain the first year.

Let us first take the case of what—with the class for whom these remarks are intended—is considered an early vinery, one from which all the fruit is cut by the end of June, and suppose that it has been considered advisable to renew the Vines and border to the very foundation. Let the forcing commence this year on the 1st of January, so that with ordinary forcing the crop can be all used before the 1st of July. In the meantime the soil and draining material should be all in readiness, or sufficient at least to make half the border immediately the Grapes are all cut, when the old border is to be replaced with a new one, and young Vines substituted for the old. Two Vines for every light, presuming the lights are 4 feet wide, should be prepared in the following way:—Select the required number at once from Vines that have been raised from eyes in the spring of 1863, and cut them far enough down, so that, after they are planted in the new border, last year's wood will extend up the front light to the bottom of the rafters. Set them aside in the coolest available place where they will not be exposed to severe frost, such as a shed open to the north. To prevent them from getting too dry at the root, and from requiring much attention in this respect, plunge the pots in moderately damp soil or rotten tan. In spring, when they have burst their buds and given signs of growth, they should be totally shaken out of their old soil, and planted in shallow boxes formed of pieces of double lath or hazel rods in the same manner as Orchid-baskets are often made. These receptacles may be about 18 inches long, 14 inches wide, and 6 inches deep. Into these the Vines should be carefully planted, and they must then be removed to a cool, light, airy house or pit, where with but very little attention they will progress slowly, making comparatively short but strong, vigorous, young growths by the end of June, when it is supposed all will be ready for them in the vinery for which they are intended. In planting them, the strong wickerwork with which their roots are encased can be easily removed, piece by piece, without injuring the young roots. One of them should be planted at each rafter, and one at the middle of each light. As soon as they are planted give a good watering of tepid water to settle the new soil about their roots.

All is now in readiness for a rapid march to the top of the house: a smart temperature and an ordinary amount of moisture should be steadily kept up till the Vines reach the top of the rafter; then the moisture should be decreased gradually, and a free circulation of warm air kept up by opening ventilators at top and bottom, by which means a well-ripened strong growth may be secured by the end of October. One-half of the Vines should be stopped as soon as they reach within 3 feet of the top of the house, with the object of obtaining well-filled-up fruit-buds to fruit in the following season. The other half of the Vines may be allowed to ramble after reaching the top of the house, but not to such an extent as will crowd the other Vines or even themselves with foliage. As soon as the leaves drop off cut down the

Vines which have been allowed to grow very much as they pleased, with the view of making roots, to within 3 feet of the front sash, and shorten those which are intended to fruit next season to about 4 feet from the top of the house. Thus there is a viney furnished with Vines in a condition to yield, if not quite so many bunches as the original occupants did, still finer Grapes by far.

In the year 1859 I cut a crop of Grapes from a house, and planted it in the end of June with Vines struck from eyes that same spring, and had a good crop in the house in 1860. The Vines were planted outside, and introduced through openings in the front wall. I would in that case have much preferred a set of plants prepared and planted as above directed; but when to be planted inside I would just as soon have Vines struck from eyes, although in all cases one-year-old Vines are safest in the hands of the inexperienced. Perhaps some are ready to say that by this system you greatly damage one-half of your Vines by cropping them heavily the first year after planting. Any injury they may sustain must, however, be borne with when an exceptional case or want is to be met. But in my own experience I have found that by cropping lightly in the second and third years the Vines become vigorous enough when in a good border. Sometimes young Vines which are cropped so heavily the first year are then cut back to the bottom of the rafter to give them a fresh start. This is a practice I do not approve of, for the sooner I can get established spurs and close pruning, the more certain is the production of compact serviceable bunches. In some cases I have planted three Vines to a light, and cropped one heavily, and then cut it entirely out. But I prefer the system of two Vines to a light of 4 feet wide; three in so limited a space crowd one another too much. With the five and six-foot lights to be met with now in new erections, three would be the best arrangement; the two to be retained would then have sufficient room, and all the fruit could be allowed on the third and temporary one that it could bring to perfection.

Another arrangement that I have had recourse to, is to cut out the old Vines in autumn, make the border in the course of the winter, or early in spring, and having prepared two fruiting pot Vines for every light, to place one at the bottom, and one at the top to be trained down, at the same time planting the permanent Vines, and as soon as the fruit is cut from the pots, to remove them out of the way. This is the best method in the case of late-ripening vineeries from which the crop cannot be cleared soon enough in the season to let the young Vines establish themselves and ripen before winter. By adopting the system of fruiting in pots the permanent Vines can, of course, be planted at the proper time, and have all the season before them to make finer canes. It entails, however, more labour, and in the case of many who have not means to prepare beforehand the required number of pot fruiting Vines, it might be considered expensive to purchase them.

There is another way which is adopted with success where there is a border both outside and inside the viney. A temporary border of light, rich soil is made on the surface of the old outside border, very much in the same way as Mr. Lane, according to Mr. Fish's description, has formed his Vine-border on the surface of the natural level. A few of the most worthless of the rods are cut out of the viney, and those left are trained wider apart, so as to admit of the young ones planted in the temporary-border manner being trained up between them. Should these young stop-gaps not make strong growths in the first season, they must be cut down, and they will do so the next. Young Vines never run up so vigorously among old plants as when a wholly new lot are planted together. In the second year the old Vines are cut out, and the young are in their place to give Grapes. In the same season in which the old Vines are done away with, the inside border is cleared out, the arches built up, and a set of permanent Vines planted inside. The arches are built up to keep the roots from running out into the bad border, which they are ever prone to do, for Vines always send three-fourths of their roots outside when they are planted inside. As soon as fruit can be had from the permanent Vines the stop-gaps are done away with, the outside border made, and the arches opened, and so in the course of three years there is a new and good foundation to go on with. This is a tedious way of accomplishing the

object, but probably some may prefer it to the entire want of Grapes for even one year.

It is in contemplation to rebuild two very old vineeries here next autumn after the crop has been all cut, and as the reconstruction of both from the very foundation is necessary, the Vines will have to be done away with. The Grapes in the earlier of the two will be cut in May; and with the view of having Grapes in these in 1865, the plan proposed is to bring on a lot of young Vines to be ready to shift into 16-inch pots as soon as the Grapes are all cut, and to grow enough of 10 or 12-foot rods to give a Vine for each rafter in both houses, and, as soon as the fruit is cut from them, to remove the pot Vines out of the way. Thus different circumstances require different modes of procedure to meet the end in view. In the latter case the lights will be 5½ feet wide, so that there is plenty of room to plant the two permanent Vines, and fruit the Vines in pots in the same light without injury from crowding to either.

I am not, however, an advocate for planting or fruiting any Vines besides those that are to be permanent in the renewal of vineeries, and the practice is not to be recommended unless in such cases as are being dealt with, where the entire loss of a crop for one year is an inconvenience. Where there is anything besides the permanent Vines, it cannot be said that they get every justice the first two years when any of the arrangements proposed are carried out. But, on the other hand, there is no permanent injury arising from any of the modes referred to, and it is much more easy to become reconciled to any little disadvantage to which the permanent Vines are subjected for a couple of years than to the entire want of Grapes for the season.

There is another matter which often frightens owners of small gardens from renewing their Vine-borders, whether they retain their old Vines or not—namely, the idea that good Grapes are not to be produced except in such soils as are described as fine, calcareous, fibry loam, &c. No doubt such a staple is the best for Grapes, but it is not by any means indispensable, and no one need be deterred from cultivating the Vine with success who can command any common garden soil that is not very clayey in its nature. Common loamy soil from a garden quarter, with old mortar rubbish, bones, and a little well-rotted manure, will, with attention to other points of good management, produce excellent Grapes—far better than will the sloughs of despond which were not long ago compounded by certain growers, and by some very properly termed "witches' caldrons," composed of turf and loads of muck, with carrion, and every other gross item that could be thought of. Such masses of corruption might give stronger growths, but not fruitful ones, for a year or two; and the ultimate decline of the Vines is certain in such borders, entirely opposite as they are to the nature and requirements of the Vine. The natural soil laid on a dry bottom would, in many cases, be much more satisfactory than a good deal of the border-making that is carried out; and it may safely be said to any one who is desirous either to improve his old Vines or to plant new ones, that turfy loam is not indispensable to very healthy Vines and good crops of Grapes.

D. THOMSON.

EXHIBITING ROSES.

I AM glad to find that one Rose-grower at any rate has expressed his opinion on this subject, and that on some points he seems to agree with me; and I hope that many more may be induced to give their views on the points mooted, as we may thereby benefit the whole Rose-growing community. As I write this away from home, and have not my former paper to refer to, I must trust to a not-very-retentive memory in replying to your correspondent, "P.," who talks about logic, but whose opening paragraph exhibits a sad deficiency of that sometimes-useful article; for he first finds fault with me for not entering into the question whether Roses ought to be exhibited as single blooms or trusses, and then declares that I said they ought to be shown in trusses. If I were guilty of the first charge I could not clearly be of the second; but in truth I did not enter into the question of single blooms, but into the definition of a truss. Many Roses, such as Louise Peyronny, rarely have anything but single blooms, yet I should call that a truss. No: the question in my mind, and which I thought I had

made intelligible was, whether that could be called a truss from which some blooms had been taken, but that at any rate some rule ought to be framed with regard to the dis-budding as there is one with regard to additions; and I did express my opinion that a truss should be shown as it grew, because I believed the practice of dis-budding tended to give us coarse Roses, and I say so still notwithstanding "P.'s" disclaimer. I cannot agree with the sentimental notion that a Rose cannot be coarse. I have seen a stand ("pan" I cannot apply to the Rose), of Anna de Diesbach, naturally a large flower, so thoroughly out of character by excessive cultivation that it might very well have been mistaken for one of Pæonies. I have seen, too, even Général Jacqueminot so large that all the colour was washed out of it, and the character of the flower entirely gone. I have, too, in my mind's eye other stands, where all the beautiful variety of tint had vanished because of the very high cultivation.

And then as to "P.'s" desire of getting medium-sized Roses up to the size of the larger ones for the sake of producing uniformity in a stand, I would say that I hate uniformity. I think a stand where the size of the bloom is graduated infinitely preferable to one where the blooms are all alike in size. We know that the same holds good in Dahlias, and many a flower is described as a "noble back-tier flower," and others as "good for a front row." So again with Tulips. I do not, therefore, think there is anything in "P.'s" statements here to make me alter my opinion. Then, again, there is the same confusion, I fear, in "P.'s" mind with regard to my observation about the "natural production of the shoot." I did not use that to show that Roses should be shown as trusses, but why a shoot dis-budded to one bloom could not be called a truss. He triumphantly asks, What is the natural production of a shoot in a Carnation, or Pink, or Hollyhock, or bunch of Grapes? I will only reply these are not called trusses. Would—for this is the point—"P." call that a spike of Hollyhocks from which every flower but two or three had been taken? Would he designate a dozen monstrous-sized berries as a bunch of Grapes? The Pink or the Carnation have nothing to do with the question, as they are invariably shown as single blooms; and into the respective merits of single blooms and trusses I beg again to remind "P." I did not enter. I must own to preferring trusses to single blooms; but I think that the various tastes on that subject might be met by giving some prizes for the one and some for the other, which might easily be done if some of these Fancy classes were discarded, which only tend to confirm and give wrong notions to those who are merely lookers-on.

I find again that "P." differs from me as to the separation of the classes; but as he does not adduce anything in opposition to what I have stated, it will not be necessary for me to say much on this point. There is an old saying, "The proof of the pudding is the eating." We have never yet, I am glad to say, seen stands of Hybrid Perpetuals only. We have seen them of Moss Roses and Teas, and I am perfectly satisfied that they have never met with approval from those who have seen them. A Moss Rose is very beautiful as a bud, but in no other way; and a stand of buds does not sound very lively at any rate, while half or fully-opened blooms look unusually poor alongside the brilliant and beautifully-shaped Hybrid Perpetuals and Bourbons; and Teas are miserably washy by themselves, although most lovely as a contrast or as a single bloom for a vase.

I hope there is nothing in these observations which "P." will consider discourteous, and that he and others will frankly state their views. These are matters which always are the better for being ventilated; and if we could only induce Rose-growers to give their opinions on them before another season, some of the shows might perhaps be regulated as the wishes and views of exhibitors may tend.

Another paper on Roses in the same Number has set me thinking on another point that I should like to have information upon—viz., as to the sorts which best suit the various localities, for there can be no doubt that there is a great difference on this point; for while there are sorts which are good everywhere, and will grow everywhere, there are some also which are better in one place than another. As a rule, I should think the fuller Roses would do better in the south, and those less so in the north; but a certain

amount of fullness is indispensable. When Roses show the eye their beauty is to a great extent gone.

Since I wrote on the Gladiolus I have lifted my bulbs, and have been surprised at the wonderful growth of some of them. I may mention that a small-sized bulb of Helen, one of Mr. Standish's seedlings, produced, besides a number of offsets, two bulbs, each of which measured $11\frac{1}{2}$ inches in circumference; and I have seen nothing in the bulbs in general to induce me to imagine that I shall have any disease amongst them. I am now carefully drying them.—D., Deal.

A PLEA FOR ORCHARD-HOUSES,

WITH REMARKS ON THEIR MANAGEMENT.

THERE is no system in gardening which has been introduced during the last quarter of a century, that has had to contend with so much opposition as orchard-houses. They have had to battle against ignorance and prejudice to a serious extent. Some of our most eminent men in horticulture, as we thought them, have come forth marshalled against it, with a determination to crush the system if possible and send it into oblivion. But, notwithstanding this, orchard-houses still exist, and are on the increase; and during the last ten or a dozen years, they have sprung up to a great extent all over the country.

There can be no doubt but a well-managed orchard-house is one of the very best modern improvements in horticulture for the growth of our choice and tender fruits in this our precarious climate. I am aware that many people have failed in the production of large crops of fruits from trees in pots. I remember about five years ago when a resident in Kent, visiting a gentleman's place of large extent, a few miles from Maidstone; and in going through the forcing-houses, the gardener pointed out to me and a friend who was with me, a number of Apricot trees in pots, destitute of fruit, a circumstance not to be wondered at. Now he, not being able to succeed with the growing of Apricot trees in a forcing-house, condemned the system *in toto* of growing fruit trees in pots. When we remember that the Apricot is a native of the snow-clad mountains of Armenia, the slopes of Caucasus and Ararat, it is no matter of surprise that it should refuse to flourish and produce its luscious fruit in the confined air of a hothouse. This is not the only instance in which I have seen the Apricot fail, and judging from my own experience, I consider the Apricot the most precarious of any of our orchard-house fruit. I have known others who stand high on the pinnacle of fame, who have attempted to grow pot fruit trees, but through some cause or other that I am not acquainted with, have failed in their endeavours, and therefore given up the system in disgust. Now it does not follow that because a few have failed all should do the same. I presume that orchard-houses are at present only in their infancy; we have much to learn with regard to their management, and past successes only indicate how much more may be accomplished by diligence and attention.

Having the charge of a small orchard-house, I can testify to their adaptability to places of limited extent. The house is a lean-to on the principle patented by Sir Joseph Paxton, is about 40 feet long, 10 feet or 10½ feet high at the back, 4 feet high in front, and about 10 feet wide. There are two Peach and two Nectarine trees planted on the back wall. There is a border 18 inches wide in front of them, and then a trellis 18 inches wide to walk on; this leaves about 7 feet between the trellis and the front wall, which space is devoted principally to Peach and Nectarine trees in pots. When I took charge of this house and others two years since, there was a greater variety of trees occupying this space—including Peaches, Nectarines, Cherries, Plums, Apricots, and Pears. During 1862 the trees made such rapid progress, that in the past summer we could only accommodate about six Peaches and six Nectarines, with two or three Pears. Now let us look at the produce of these twelve potted trees. The trees on the back wall have been planted three years, and my greatest difficulty with them is to check overluxuriance, notwithstanding the severe root-pruning they underwent last winter. But to return to trees in pots. When the blossom-buds began to expand, about the beginning of March, we gave them the advantage of a little artificial heat, as

the house is supplied with a three-inch flow and return pipe. I believe that ten out of every twelve Peach and Nectarine trees set ninety-nine out of every hundred blossoms; two trees out of the twelve did not set so well, which I attributed afterwards to a defect in the drainage. The first fruit from Hunt's Tawny Nectarine was ripe on the 10th of August, and the tree kept in bearing until August 31st, when the last fruit was gathered. It produced about four dozen, and most of them were quite equal to what are generally seen on walls. On referring to my memorandum-book, I find the first time I saw this beautiful Nectarine was at the Royal Botanic Society's Exhibition, Regent's Park, in July, 1861, when I considered it the prettiest Nectarine I had ever seen. Next comes Acton Scot Peach, a variety so well known that it requires no comment. The first fruit was ripe August 11th, and the tree was in bearing until September 1st; we gathered about four and a half dozen from this tree. Early York Peach was ripe August 12th, and the last fruit was gathered on August 21st. It is a fine early Peach, but growing by the side of Acton Scot it was one day later than that variety. The first fruit of Royal George was gathered on August 15th, and the last on August 31st. It was a small tree, but bore a heavy crop, two and three Peaches on one small shoot where only one ought to have been left. The fruit weighed about 5 ounces each. The next in succession was a small Elruge Nectarine with only a medium crop; it supplied fruit for eleven days. Duchess of Oldenburg Nectarine ripened its first fruit August 21st, and the last was gathered September 4th. Many of the fruit were extremely fine, and the tree carried about two and a half dozen. A larger tree of Elruge Nectarine, but only in a 13-inch pot, was allowed by way of experiment to carry six dozen, which it ripened and coloured satisfactorily. It was in bearing three weeks; thus one pot tree alone supplied two dozen of fruit each week for three weeks. Violette Hative Nectarine kept up a supply for ten days, the crop was medium, but the fruit good. The same remarks apply to Pitmaston Orange Nectarine, only the fruit was still finer; no collection should be without it. The Angers Late Purple Peach is a later variety, it is a beautiful large Peach, and was the admiration of every one who saw it, but the fruit is liable to fall before it is perfectly ripe. My employer speaks of it as being fine for tarts, as some of the unripe fruit were used for that purpose. I have no doubt they would make excellent *compôtes* as described by Mr. Rivers in his book on orchard-houses. It was in use from August 29th until September 15th. Two other Peaches, Noblesse and Vineuse de Fromentin, did not set very freely for the reasons above stated, and not looking equal to the rest I pulled the fruit off. Having made the defective drainage good, the trees are in equal health with their neighbours, and judging from the round plump buds with which all the trees are covered "from stem to stern," there is the promise of a better crop of fruit next year.

With regard to growing Pears in orchard-houses, some people seem to sneer at the idea. It is all very well for those who are situated in the southern and western counties of England; but here in this cold and cloudy district, where we only have, perhaps, two tolerably good Pear seasons out of seven, orchard-house Pears are invaluable. I had this season a Louise Bonne of Jersey Pear in a 12-inch pot in the orchard-house, which bore fine fruit, while one of the same variety planted outside, with space for the roots to ramble at large, was not one-quarter so fine. There was, in fact, as much difference between them as there is between the best Grapes I have ever seen at the metropolitan exhibitions and the rubbishy little bunches on the cottage walls near London. The same may be said with regard to other Pears. Last year I grew Soldat Esperen Pear in a 12-inch pot in the orchard-house; but not being able to find it accommodation this season it was planted outside, and has produced a nice sprinkling of fruit. I believe that one Pear of last year, when grown in a pot under glass, would weigh as heavily as six produced this season out of doors. I might multiply instances, but forbear to trespass on your valuable space.

I will now briefly advert to the management of orchard-house trees, confining my remarks chiefly to Peaches and Nectarines, and I shall state what I have practised myself. We will suppose that the trees are in 13-inch pots, and that it is autumn. The trees, if in a healthy condition, will now

be losing their leaves, and the wood will be fully ripe. The principal point now to be attended to is the top-dressing. I top-dressed my trees about the end of October; the compost for the purpose, consisting of about two-thirds decayed turf, and one-third rotten manure and sifted bones, was well chopped and mixed together, leaving a good portion in lumps as large as an egg. It was placed in the orchard-house about ten days before it was required for use, and when that time arrived it was dry and in a workable condition when wanted, and also of the same temperature as the house in which the Peaches and Nectarines were growing. The first wet day we had towards the end of the month was taken advantage of to supply the trees with their fresh food. I remove a quantity of the old soil from the surface of the pots, and one-third or nearly halfway down between the sides of the pot and the ball, and several inches in width, according to the size of the pot. This space is filled up with the fresh compost, taking care to ram it firmly as the operation proceeds, for the more firmly the soil is rammed the more food will there be for the plant. I then give a soaking of water to settle the fresh soil about the roots, and the trees are placed close together, as they will do with half the space in winter that they require during their season of growth. This is one great advantage in having the trees in pots, and it leaves plenty of space for the protection of Strawberries for forcing. Late Cauliflowers not having perfected their heads in the kitchen garden can be taken up and laid in by the heels, as also early winter Broccoli; and if the weather proves very severe these will give a supply of nice small heads in winter, and be found extremely useful.

It has been recommended that the trees should have no water, or but very little, from October to February. This I consider, with all due deference to the opinions of my superiors, a mistake, and I believe that following this advice to the letter is the source of endless failures. The ball becomes perfectly dry, and the roots confined within the limits of a pot cannot ramble away from home in search of food and moisture. The consequence is the buds shrivel, and either fall off or expand very weakly. It is necessary to make some allowance for the difference in the houses in which the trees are cultivated. In houses heated by hot-water pipes, or supplied with any other artificial heat, when those means are brought into use during seasons of extreme frost, unless the pots are covered with a good thickness of litter the soil will become extremely dry; and, therefore, more water will be required than when the trees are in a house without such artificial appliances, and where they are covered with litter from the time they are top-dressed. I would by no means saturate the balls in winter; but I believe one very important step to success is to avoid extreme dryness.

About the beginning of February, or should the weather prove mild and sunny even by the end of January, the buds will begin to swell, so that the uninitiated may be able to distinguish without much difficulty the fruit-buds from the wood-buds. The young shoots should be shortened to within eight or ten buds of their base for bush trees, always cutting to a wood-bud, and keeping in mind the symmetrical shape of the tree designed to be formed. When some of the side shoots are allowed to grow 15 or 18 inches long without stopping in the summer, I have frequently observed that they will be set with single fruit-buds nearly from their base to their terminal point without any wood-buds. In such cases I would not shorten the shoot, as all the buds would ultimately fall off; but to prevent the tree from acquiring a straggling habit by encouraging such lanky branches, I would allow the shoot to break at its point, keep it pinched-in during the succeeding summer, and encourage a fresh shoot from its base, as there will often be two or three leaf-buds at the base of such shoots, and then at the following winter's pruning the old shoot must be removed close to the base of the newly-made shoot, and the new one allowed to take its place.

When the pruning is finished, the trees should be painted all over with sulphur and soft soap, about a quarter of a pound of soft soap to two or three quarts of water, with as much sulphur as will give it the consistency of paint, and a little clay must be added to cause it to adhere to the trees. This mixture must be well applied to every part of the tree

with a painter's brush, taking care to work it in underneath the buds. During the resting period the trees should be exposed on all favourable occasions to a free circulation of air, for if the house is kept too close in early spring and the weather is either mild or sunny, it will cause the blossom-buds to expand prematurely. When the buds begin to swell the trees may be syringed daily when the weather is fine, until the flowers commence to open, and when in bloom a dry atmosphere must be maintained with a good brisk current of fresh air continually rushing through the house. If, while the trees are in bloom, the weather should be dull and cloudy, a little fire heat during the day with plenty of air will be found useful, and artificial means of fertilisation must be had recourse to, by simply passing a camel's-hair pencil over the anthers and stigmas, to distribute the pollen which adheres to the anthers without being properly dispersed. A light hand and nimble fingers will soon pass over a large number of trees. When the air is dry my employer will occasionally give the trees a rap with his walking-stick as he is walking through the house. The temperature of the house while the trees are in bloom should never range higher than 55° by day unless by sun heat, nor more than 45° or 48° by night.

As soon as the fruit is fairly set, syringing may be again commenced and carried on until the fruit is changing colour, when it must be discontinued. The end of the syringe should be pointed underneath the leaves, as there the red spider will take up its quarters, and it is well known that it is no advocate of the hydropathic system. The fruit being pretty secure may be thinned, leaving a few more than the tree is intended to carry, as during the stoning period some are certain to fall. The trees will now be smothered with a host of young shoots, which must be considerably thinned, reserving those shoots nearest the base of the previous year's wood. As the trees advance in growth they will require the points of the shoots to be pinched out. Much of the mode of pinching will depend on the shape which the tree is desired to take; when it is intended to form it into a close conical-shaped tree, the shoots must be pinched very closely, to within three or four buds of their base, and as they keep putting forth fresh shoots these must be pinched again and again. When the tree is intended to be formed into a bush the shoots may be allowed to grow rather longer before they are pinched, the laterals or side shoots should be pinched to within one bud of the base, and the leading shoot at every five or six buds. Weak manure water will be found useful twice a-week after the fruit is set, and the temperature may be raised from 16° to 15°. The trees may also receive a surfacing of rotten dung with advantage, and the dung not washed away by watering will be found in the autumn one mass of roots. They must receive no stimulants during the time of stoning or the fruit will fall. The trees are then enjoying a partial rest, and therefore must not be excited either root or branch. When the fruit is stoned it must be finally thinned, not leaving too many on a tree. As they approach maturity the atmosphere of the house must be kept dry with plenty of air, or the fruit will be liable to crack. During the whole of the growing season they will require copious supplies of water; but when the fruit is gathered water must be given more sparingly.

I have endeavoured to touch as briefly as possible on some of the leading points in the cultivation of these beautiful trees. I might considerably enlarge on the subject, but fear lest I should encroach on your space. I am certain that to any one with only a small orchard-house and only a limited number of trees, if those trees are treated properly they cannot fail to afford an endless source of pleasure. The cultivator watches with feelings of intense pleasure the expansion of the first blossom-bud, the untolding of the leaves, the development of the fruit; and as it approaches maturity and he breathes the fragrant odour which it exhales, he cannot fail to feel thankful to the Giver of all good things who so bountifully supplies His creatures with these charming fruits.—*QUINTIN READ, Gardener to the Rev. W. H. Holt, Biddulph, near Congleton.*

MISTLETOE.—I observe, among the answers to correspondents, in your Journal for Nov. 24, that you ask for information respecting the Mistletoe. On referring to my journal of

1859, I find that during that year it was growing on the Lime, Apple, Thorn, Oak, and Maple, all in this neighbourhood, but chiefly on the first three trees. There is plenty growing in this part, but up to this time I have not traced it on any other tree.—*W. DIVERS, Gardener to Wm. Moore, Esq., Wierton House, near Staplehurst, Kent.*

HAVING read an account in *THE JOURNAL OF HORTICULTURE* of Nov. 24, respecting the Mistletoe growing on various trees; I beg to inform you that there is a very fine bush of the Mistletoe growing luxuriantly on the Acacia—viz., *Robinia viscosa*, in the Priory Gardens, Great Malvern, the residence of Dr. Guiley.—*JAMES WATKINS, Gardener to C. Lawrence, Esq., Cirencester.*

SMALL OR LARGE BRUSSELS SPROUTS,

WHICH ARE MOST WORTHY OF GENERAL CULTIVATION?

I SENT three dwarf heads of what I consider extra samples of Brussels Sprouts for the opinion of the Fruit Committee of the Royal Horticultural Society at Kensington. They were about 14 or 15 inches high, and closely studded with most compact firm sproutings. The opinion of the Committee was that they are too large ever to become a variety of any importance, seeing that the desideratum in that vegetable is to procure it as small as possible. I consider, then, that it would be a matter of no small public importance to know the criterion of a perfect specimen of a profitable kind of Brussels Sprouts, combining every property worthy of cultivation. The Committee think that to have the individual sproutings as small as possible is the chief object. Will that be the size of a round button or the size of a boy's play-marble?

The great desideratum I consider in every vegetable is to have a variety that will produce the largest quantity in a given space of ground, but in a perfect condition for table use. The samples sent, no doubt, had every individual sprouting the size of three marbles. Now the produce of the latter will be more than double, and still be in a condition perfectly fit for the table of any gentleman, not to speak of the million to whom it is invaluable as a winter dish.—*WM. MELVILLE.*

[We have made inquiries, and find from members of the Fruit Committee well acquainted with the subject, that the Brussels Sprouts preferred for first-class dinner-tables are those which, being the size of a boy's play-marble, are at the same time very compact and firm. By "the million," with whom quantity is a prime consideration, your new variety may be highly estimated.]

For appearance at table, as well as delicacy of flavour, we agree with the Committee that the smaller sprouts are preferable. In addition, we will add, that if the smaller sprouts are produced as densely clustered round the stem as we have seen them, we think there would be little difference between the weight of produce of them and of the larger sprouts.]

MATERIALS USED IN FORMING COMPOSTS.

(Continued from page 487.)

SAND.—Most soils contain a certain portion of this; in fact, it may be truly said that sand exists in greater or less quantity in all soils supporting a vigorous vegetation, although the character of the sand, or rather the substances it is incorporated with, may differ very much in the individual compounds. A mountain peat contains a large proportion of sand, which, however, differs widely from that found in the dry upland tillage fields of certain districts. The grit itself may be the same in both cases, but the chemical substances with which it is incorporated make a wide difference in the action it has on vegetation. It is, however, an essential ingredient in all the artificial compounds in which choice plants are grown, and some circumspection ought to be used as to the kind of sand mixed with the other materials forming the compost.

I have already stated that sand exists in most soils, and most likely in those to which it is added on the potting-bench; so before going into the merits of the different kinds

it would be well to still further investigate the matter, and ascertain what are the various conditions in which vegetation is found when in contact with sand in greater or less abundance. In the first place we may examine the sandy beech subject to the heavy spray of salt water; a certain description of vegetation exists there, more or less vigorous as it is afforded shelter; but the sand having been so repeatedly saturated with salt water is unfit to grow anything in but what delights in abundance of salt. Certain plants seem to relish large quantities of salt, and to such the sand of the seashore is at all times acceptable. Asparagus and Sea-kale both delight in a salted medium, and they, of course, cannot well have too much; while with many of the hardwooded plants inhabiting stations more inland, sand strongly impregnated with saline matter is almost fatal to them. Sand from the seashore has, therefore, been in a great measure banished from the potting-shed, and is, perhaps, only recommendable as a substance in which to pack Carrots, Beet, and other roots which require to be kept from withering, and also from the action of worms. Celery taken up on the approach of severe weather, may also be safely stowed away in such sand, and the same may be said of Horseradish. It is also very convenient, when in a frame or pit, to receive the balls of Endive plants that may have been transported thither prior to hard weather setting in. I am not certain but that a due proportion of sea sand might also be added to the Peach-border if the latter be dry; but there, except in a few other cases, its utility as a gardening agent may be said to end, and another kind of sand must be used for the other purposes for which sand is required.

Perhaps the next abundant supply of sand which a district contains will be what is usually called pit sand, such as is met with in layers, often of great thickness, under the surface. Sand-beds, or pits, exist in most districts. Even the great breadth of clayey lands we hear of existing for several miles at a stretch have, nevertheless, now and then a break in their strata, and sand in one form or other is found. Of the various kinds of sand thus met with, colour is, perhaps, the least important point of merit, although it is much looked at, and if it should be white its presence is the more conspicuous; but yellow, brown, and grey sands are, nevertheless, equally good in their way, and may each be used when they possess the necessary qualities fitting them for the purposes for which they wanted.

White pit sand is a favourite with the propagator of hardwooded plants, when it is free from all pernicious chemical substances, and has been sufficiently exposed to the action of the atmosphere to sweeten and prepare it for the roots of delicate plants first forming rootlets in it. Pit sand, however, is sometimes anything but favourable to the plants growing in it, some chemical substance entering into the mixture at once fatal, or, if not, certainly hurtful to vegetable life. Generally speaking, the merits of a sand for the purpose of mixing with other substances, may be guessed at by the condition of such herbage as exists upon it where it is found. The most pernicious substances, it is true, acquire a certain amount of fertility by exposure to the atmosphere, but the long period which must elapse before they attain this condition must be taken into account. If a few spadefuls of sand are taken from a considerable depth below the surface and spread thinly on the ground, it will more speedily part with its noxious qualities, and acquire those necessary to make it a fit agent to support vegetation, than if a larger quantity were brought to the surface and then piled up in a heap.

Some pit sands contain salts of various kinds, others iron, and some—for instance, those found in certain places in the south-west of England—a large amount of copper, and these last are, perhaps, the most pernicious of all, killing vegetation when they come in contact with it. Thus, unless the amateur has some knowledge of the component parts of pit sand, or has the means of judging of its effects on vegetation at the places where it is to be had, he had better refrain from using it and adopt the next kind that will be described, which is

River or Drift Sand.—By this I mean not sand from a tidal river, and containing more or less salt in proportion to its proximity to the ocean, but sand washed by some clear fresh-water stream, not poisoned by any chemical agent that unfits it for the purpose for which it is wanted. Gene-

rally speaking, most fresh-water streams throw up beds of sand at places along their course, and these, having received repeated washings, have parted with all deleterious matter, and are fit to apply to the roots of anything requiring an open, coarse, gritty sand. This kind of sand may, therefore, be used without fear. Perhaps, however, a sand containing more fine matter may be wanted, especially for the finer work of striking cuttings of such hardwooded plants as are slow and difficult to propagate. In this case another kind of sand may be advisable, but for general purposes of mixing the sharp gritty sand will be found the best. Drift sand, however, is not confined to that found by the sides of rivers and streams, but in many instances the sides of public roads present it in quantities more or less abundant as the character of the material the road is formed of differs, but the beneficial effects of the rains which fall, coupled with its exposure, purify it to a certain degree of most of its hurtful constituents. Road sand may, therefore, in most cases be safely used. Perhaps, however, it ought to be only sparingly applied to Heaths and similar plants when it is taken from a road composed of flinty or chalky matter; but such roads afford much less sand than those made of stones of a contrary description, and in both cases it is materially improved by the action of the atmosphere and the rains that wash out much of the foreign matter. Sand, also, abounds in some soils to such an extent as to make them appear all sand, and the surface sand of such places may be used with advantage for plants resembling in character, or rather in their wants, those found wild there. We have seen a sandy hill covered with Rhododendrons in the most luxuriant health, and, of course, such a sand might be safely transported elsewhere for their use; but, generally speaking, these places do not exist in sufficient abundance to supply the wants of those who may require a few barrowloads of sand; and such as have no other means of ascertaining the quality of the article found in their neighbourhood cannot well do better than procure some from the edges of a stream, or, in the absence of that, let them try the road sand. The weeds which the latter will produce from its contact with hedge plants, &c., is one proof of its fertility.

Having described charcoal, burnt clay, peat, and sand as substances used in the formation of artificial compounds suited to the wants of plants for which a soil exactly to their liking did not previously exist in the same proportions, I shall now take a step in another direction, and point out some substances which, perhaps, ought properly to be regarded as manures, and, consequently, as stimulants. These substances are in themselves so numerous that any attempt at fully describing them would occupy more space than could be afforded, and besides, most of them are so well known that a repetition of their properties is needless here. There is, however, one point which is not, in general, sufficiently thought of when manures are applied to a plant, and which it would be well to point out here. It is, Whether such manure when applied is intended merely as a stimulant to benefit the plant for a short time only, or is wanted to supply that plant with a store of food on which it may rely for a considerable period. Attention to the latter requirement has only recently been acknowledged as of importance, and is yet far from being so general in preparing compounds in which plants are to be grown, that I cannot but advert to the matter; in fact, it is this especial subject that has induced me to conceive this article.

Quickly decaying substances are, no doubt, of great service to plants of rapid growth requiring strong stimulating assistants when young, but their nourishing properties are all expended by the time the plant has attained maturity, or, perhaps, before, and the residuum is incorporated with the soil whether there is any chemical affinity between the two or not. Now, some plants, such, for instance, as the Vine and all fruit trees, and even plants of a more herbaceous character, have a prolonged growth, and, consequently, require long-continued and well-sustained feeding during that time. They consequently require a soil or substance open enough to receive such foreign matters as may be supplied: hence the large quantities of inert matter which enter so largely into the composition of so many of the best Vine-borders of the country; but as many of these substances are indestructible, or nearly so, we will pass them by, and

go on to specify such as are in themselves good manures, but which, nevertheless, do not too quickly fall into the condition of complete decay. The list of such things is a larger one than I can give, and I will confine myself to calling attention to one or two; those which I recommend being vegetable matters, not by any means of quick growth, but which are of a tough fibry nature, have taken years to attain their present condition, and during that time have been exposed to all weathers.

Moss.—Beginning with this, I must observe that the kind I mean is that found on moist waste places where the land is poor, and where other and more useful herbage has given place in a great measure to this low but persistent plant. Moss, such as is used in nurseries for packing, might very often be applied to other purposes with great advantage, especially to such plants as have long rambling roots and delight in sending them forth in search of that food which does not exist close to their collar. Moss has long been used as an important adjunct to the compost in which Pines are grown, and the proportion so used is often a large one. When covering the broken crocks at the bottom of a pot it is often the receptacle of as many roots as can find space there; and if it should happen that plants of various kinds have been plunged in a bed of Moss, the rapidity with which the roots find their way into it, and occupy it, proves how much they like it. Moss, also, has a quality of its own not possessed by many things in which plants live and thrive. A Hyacinth will root and flower well in a handful of damp Moss, and that Moss can be handled and moved about without employing a flower-pot or other vessel to hold it together. Returning to the subject of Pines, I do not know of any way of managing suckers, or, it may be, crowns that are wanted for future plants better than tying a handful of Moss about their base with a piece of matting, and planting them either in pots or in the bed. They root very freely through the Moss and quickly become good plants.

One of the especial purposes we apply Moss to here is, in the spring when the number of bedding plants alike require everything in the shape of a pot, and also every inch of glass. At that time we make up a slight hotbed often of short grass and old loam mixed, and cover it with light leafy soil. We then separate the store-pots or boxes of Geraniums and similar plants, and tie a piece of Moss around the root of each with a small portion of soil inside the Moss, the whole being about the size of an ordinary lemon. The plants are bedded closely together over the slight hotbed, and protected in due course for a short time, and nothing can be more satisfactory than the way in which they root into the Moss, interlacing it in all directions with their fibres, and by degrees entering into the soil of the bed. By the time they are usually removed to their final quarters for the summer, the shallow bed on which they obtained a slight warmth to start with having subsided into the ordinary temperature of the ground, they do not receive the check which they would if removed from a hotbed to the open ground. Without Moss I do not know how this mode of managing bedding plants could be carried out, as on one or two occasions when we were accidentally obliged to use short straw and grass instead of Moss, the difference was so perceptible as to render it easy to pick out every plant not grown in the Moss; the green short grass, especially, being obnoxious to the roots of the plants, although, as it is needless to say, its decay was quick, and its manurial properties are by some held in repute. I must, however, place it many degrees below Moss in point of merit for the purposes mentioned above, and also for all others connected with vegetation with which I am acquainted.

Moss has long been employed as one of the principal ingredients in which Orchids are grown; and though other substances are used, by far the greatest proportion of cultivators employ it in large quantities as their principal medium, and some who have tried more recently-introduced substances have returned to Moss again, admitting its superiority. I, therefore, have no hesitation in strongly recommending Moss as one of the most useful articles on the potting-bench, or, in fact, anywhere. For out-door plants where the chances are that they will not receive at all times artificial waterings when wanted, the open texture of Moss admits more air amongst the roots than is sometimes consistent with their well-being in very dry weather; but

for plants immediately under the eye of the cultivator, Moss suits itself so well to the many conditions in which they are grown, and is in general so much liked by them, that I have no hesitation in pronouncing it one of the most useful substances we have, and in urging its adoption in places where an open texture of compost is wanted. Few plants will be found but what will assimilate to themselves such food as can be supplied in the Moss, for be it remembered, nothing presents a better medium for conveying liquid nourishment to a plant than Moss, and I have no doubt that it will be yet more extensively used than at present.—J. ROBSON.

(To be continued.)

WEIGELA ROSEA FOR A NORTH WALL.

As we are so often compelled, from want of an evergreen creeper suitable for back walls, or other more or less shady situations, to use deciduous and other kinds of plants not very prepossessing in winter, I think many would make use of the *Weigela rosea* did they know that it will grow, flower, and do well in such situations. It has the advantage also, of growing tolerably fast, so that it does not take so long as is generally supposed to cover a wall of moderate size. I have before stated how very readily it will strike from cuttings. Shoots of last year put in in any form, strike as easily as Willows.

It should, when first planted, have some good compost—say turfy loam and leaf mould, and, if at hand, a little peat, otherwise giving more leaf mould. Cover the wall as soon as possible with the main shoots. This done, take a spade and chop the whole of the roots clean in two, at about 2 feet from the stem, or even less, if well furnished with fibrous roots. This is the main secret for the success of this beautiful plant. I used to suppose the *Weigela* to be a very shy bloomer, but in reality it is quite the reverse, and so manageable is it that no plant can be forced to flower more readily or freely. Cutting away the roots will induce the stronger stems to break freely, and with the spray the intervening spaces can be readily covered. Digging well round the roots will always prevent over-luxuriance, and at the same time induce the plant to bloom rather later than other specimens more fully exposed to the influences of the sun.—W. EARLEY, *Digswell*.

NEW BOOK.

Cultural Directions for the Rose, by JOHN CRANSTON, King's Acre, near Hereford. London: Houlston & Wright, Paternoster Row.

So wide-spread is the love for the Rose, and so many are they who seek for and need instruction concerning its culture, that anything on the subject is sure to have an extensive sale and to be eagerly welcomed. Mr. Rivers' "Rose Guide" has passed into a ninth edition; Mr. W. Paul's "Rose Garden" has appeared in a new form; and now Mr. Cranston, with a less pretentious but most useful book, reappears with a second edition, improved and enlarged, making a full and clean breast of it—telling all he knows, and making every one of his readers his confidants. The book is divided into two parts. In the first part all the necessary directions for planting, pruning, and growing are given, and at quite sufficient length; while in the second most useful and descriptive lists of varieties suitable for all situations are added, together with those best suited for exhibition, bedding, climbing, greenhouse culture, and forcing, and all this for the small sum of 1s. 6d.

All Mr. Cranston's directions are characterised by plain common sense. Witness, for instance, what he says with regard to the selection of varieties: "The first thing the amateur generally does is to fix upon the varieties he wishes to grow; and for this purpose the catalogue is taken in hand, and those varieties described as being the most beautiful and perfect in form are chosen, without any regard to the habit or the hardness of the breed, or the nature of the soil in which they are to be grown." The result, as he states, is too often failure, which is often laid upon the nurseryman who supplies them, whereas a little more care or reliance on the vendor would have prevented this. With regard to soil, Mr. Cranston regards the dark black soil of town gardens as the worst, and a rich unctuous loam as

the most suitable. In this he agrees with most Rose-growers, as he does also on the value of the Manetti stock. His observations on pruning are especially valuable. We know so well what is too often done. "I should like my Roses pruned!" In comes gardener with his great pruning-knife: never asks what the Roses are—like quack medicines, the same treatment does for all, and the consequence is failure in too many cases. Now Mr. Cranston takes the various sections, shows how and when they are to be pruned, and the best form to be given to the plant. The diseases of the Rose and the insects injurious to it are also described, although the most destructive of the pests, the larva of the Tortrix—the "worm in the bud"—is omitted.

It would be impossible for us to give anything like an idea of the amount of information contained in this valuable manual; and we have, therefore, only to recommend all who are desirous of successfully cultivating the Rose to seek for the knowledge from one so well capable of giving it as Mr. Cranston.

OBTAINING BLUE-FLOWERED HYDRANGEAS.

In your answer to a correspondent, "J. W. L." page 458, on obtaining blue-flowering Hydrangeas, you quote from an article on that subject by the late Mr. Beaton, which shows the wonderful sagacity of that person on that as on all subjects upon which he wrote; and though from his writings I could never make out that he had any great practical knowledge of chemistry, still, whenever required he did not fail to indicate that he did possess a certain amount of knowledge on that as on most other subjects connected with gardening, and it will be long ere we see his like again, or one to assume the pen which he has for ever laid down.

I only take up mine to state what experience I have had on the subject of blue-flowering Hydrangeas, hoping it may be of use to some young aspirant to a knowledge of the chemistry of the subject.

Upwards of twenty years ago this question was much agitated in the various horticultural publications, and various were the methods proposed to cause the Hydrangea flowers to become blue. At that time I was always ready to try any suggestion which took my attention or excited my curiosity, and the production of blue-flowered Hydrangeas was one of them.

I have tried iron filings, rusted iron, and soils of all mixtures and colours, and was only successful with one, and that was Norwood loam. It was brought to the place for other potting purposes, and I used some of it for the Hydrangeas, and certainly the flowers became blue; but on using again the loam from the same heap the following year not one became blue, neither by that loam nor any other which I used.

A longer study and greater interest in the science of chemistry has often brought back to my recollection the circumstance of the Norwood loam making the Hydrangea flowers blue one year and failing the next, and I have often intended to investigate the subject, but other avocations have hitherto prevented me from making further experiments.

I shall, however, state, what I understand to be the cause of the change, and perhaps your correspondent may put it to the test of experiment, and let us know the result. The loam had been newly dug out of a deep pit, and used by myself at once. Although I never tried whether the loam contained iron or not in its composition, I think there can be no doubt but that it did, from its colour and consistency, and I am disposed to think that the iron in it, before exposure to the air, was in the state of a protoxide, and soluble in water, and in that state entering into the plant, might cause it to turn blue, while after exposure to the air the protoxide, FeO , would be converted into the peroxide, Fe_2O_3 , by combining with other two atoms or equivalents of oxygen, and being insoluble in water would prevent the iron from entering into the juices of the plant in sufficient quantity to cause the blue. It is also remarkable that Mr. Beaton says, "that cuttings struck in August failed to change colour though grown in iron filings," just, I think, because the iron was only in the state of a peroxide, and insoluble. He also says, "that by growing them in strong

yellow loam with a sixth of iron filings, nine out of ten will produce blue flowers." Now, I apprehend the reason of that is, that the yellow loam might have contained the iron in the state of the protoxide, even in smaller proportion, and hence the blue.

It is well known that the colour of nearly all yellow soils is caused by the presence of iron in their composition; and the change which takes place in those soils when turned up to the atmosphere from the pale yellow to the reddish-brown, is caused by the conversion of the protoxide of iron into the peroxide. If the former is present in any great quantity there are few plants that will grow in it. It acts as a poison, but when turned up and exposed to the influence of the atmosphere, it shortly becomes food to the plant.

If those soils which naturally produce the blue Hydrangeas were subjected to analysis it might set the matter at rest; and should any one see this who has Hydrangeas which produce blue flowers naturally, and forward by post, in a close tin box, about a fourth of an ounce of the soil in which the plants grow to my address, I will be able to ascertain in what state the iron is present in it. The soil must be taken from where the points of the roots are. Or, if any one living at Norwood would forward to me the same quantity dug from the solid, 2 feet deep, I would like very well to ascertain if I am right in my conjecture, and I will not fail to let the result be known in this Journal.

There is abundance of the soil here having the iron in the state of a protoxide. All the subsoil is so, and so poor that I do not think that were I to try I could make a Hydrangea flower in it.

If "J. W. L." tries the iron filings I hope he will let us know the result. Although I was not successful with the rust, others may be so. I am strongly of opinion that plants possess a great power themselves, when their roots come in contact with the inorganic matters in the soil, of decomposing the soil, and taking up what they require, and not so much by the chemical changes which we know are ever going on in the soil. Professor Way's celebrated experiments prove that water is not the carrier of food to the plants, only the medium, like the soil, in this important function. Both are necessary, but they must be in their proper proportions; and though the iron in the soil is not in a soluble state, neither is it soluble by adding rust, still the plant may obtain it in that state from the soil when in abundance, and so cause the blue colour of the Hydrangea.

All chemists are aware that when the ferrocyanide of potassium is added to a solution of iron it makes a beautiful blue colour with a considerable precipitate; therefore I do not see that it is difficult to conceive that a plant may have the power of making similar changes from the elements of the soil in which it grows, and so change its colour.—ALEX. SHEARER, *Yester Gardens*.

HOLLAND HOUSE.

THE SEAT OF LADY HOLLAND.

THIS is entered on the right through a splendid pair of gates from the high road between Kensington and Hammer-smith, and the beautiful old mansion is seen through the trees seated high in the park, and it is approached by an avenue of Elm trees. The chief parts of this structure were raised by Sir Walter Cope in the year 1607. To the south is the large square bowling-green terrace bounded by balustrades, lately adorned with flowers in vases of Malta stone, and four large Orange trees are in front with a large basin-fountain in the centre. To the east front is the flower garden, a rich parterre, and of a beautiful pattern. The diamond-shaped beds and circles of the chain-beds were chiefly planted with different varieties of Verbenas arranged according to their colours and shades to give a harmonious effect.

Although the experimental inquiries of Sir Isaac Newton, Sir David Brewster, and other eminent philosophers have proved that the phenomena of colours are regulated in their combination by irrefragable laws of harmony, yet the error of considering the arranging of colours as a matter of fancy merely is very prevalent. Many have likings for, and antipathies to, particular hues—all have their partialities to particular styles of colouring, some delighting in the gay

and lively, some in the rich and powerful, and others in the deep and grave; the latter may be said to be the prevailing style here. Although the rich and brilliant colours of a Turkey carpet and the gaudy dress of the rustic belle may be agreeable to some, less glaring colours are selected by the upholsterer in furnishing the different apartments of a mansion, and by a lady in the selections for her toilet.

The two larger and two smaller diamond-shaped beds, with a small triangular bed at each end, would require diagrams to illustrate the planting. Suffice it to say that the first group was planted with Tom Thumb and Flower of the Day Geraniums at each side, and there was a brown *Calceolaria* at one end and *Aurea floribunda Calceolaria* at the other. The second group consisted of Tom Thumb Geranium and Verbenas Mrs. Maclean, Field Marshal, Reine des Amazones, and Novelty. The other groups contained Verbenas Beauty of Hornsey (lilac), General Simpson (brilliant scarlet), Brillant de Vaise, Purple King, Mrs. Kaley, Robinson's Defiance, Mdle. de Nodit, Queen of the Roses, Reine des Amazones, and Lady Middleton (mauve, very fragrant, an excellent bedder, and stands the weather well). In front are eight plantations of some of the best sorts of Roses, edged with broad bands of *Tropæolum elegans*, *Gazania splendens*, *Oenothera macrocarpa*, and Verbenas of different sorts.

The chain-borders on each side of the main walk contained on one side twenty, and on the other seventeen circular beds planted in succession with Verbenas Mrs. Trotter, Purple King, Mrs. Kaley, *Gazania splendens*, *Perilla nankinensis*; Verbenas Jane, Admiral Dundas, Lady Middleton, Mrs. Holford, Defiance, André, Mdle. de Nodit, Phlox Drummondii; Verbenas Mrs. Kaley, Purple King, Firefly, Mrs. Holford, Purple King, Mdle. de Nodit, and Admiral Dundas. On the other side the beds were planted with Verbenas Admiral Dundas, Mrs. Kaley, Etonia (violet with white eye), Mdle. de Nodit, Admiral Dundas, Mrs. Kaley, Purple King, Ajax (fine scarlet), Jane, General Simpson, Purple King, Madame de Nord, Mrs. Holford, Lord Raglan, Mrs. Kaley, Purple King, and Evening Star.

The long-pointed triangular beds with scrollwork in Box were edged with Verbenas of different sorts.

At the south-west corner of this parallelogram-shaped flower garden are several beds which were planted with *Ageratum mexicanum*, Geraniums Tom Thumb and Bijou, and Verbenas Purple King, Lord Raglan, General Simpson, Mrs. Kaley, and Firefly.

The next scene is flower-beds on grass. Some were planted with Purple Zelinda Dahlias in the centre, then yellow *Calceolarias*, edged with Tom Thumb Geraniums; others with Baron Hugel Geranium, edged with Mangles' Variegated Geranium, a splendid edging; Flower of the Day Geranium, edged with *Lobelia speciosa*; and Miss Nightingale Heliotrope, edged with Sweet Alyssum.

From this, looking south through the arches of the colonnade diversified with festoons of Virginian creepers and of *Periploca græca*, Honeysuckles, Roses, &c., dangling from the top, the fine old Orange trees in rich luxuriance of foliage give an Italian aspect to the scene. These Orange trees may be called the lions of the place, and have been under the superintendence of Mr. Scobie for the last fourteen years, and with what skill they have been treated their fine healthy condition will attest to all who have the opportunity of seeing them.

The vase terrace was furnished with twenty-four vases arranged on the balustrades and on pedestals springing from flower-beds, it was gay with flowers and formed a most pleasing feature. The conservatory is 60 feet long furnished with some fine specimens of Camellias, and in the winter with the large Orange trees that lately adorned the square at the south front. They are magnificent specimens, twenty-four of them being each from 10 to 18 feet in height, and many others were not so large. Attached to the conservatory on the north side is a banquetting-room of handsome proportions, which is finished and furnished in the best style of art and ornamentation. Close to it on the east side is a tower which is approached by a flight of steps, and from the south side of the conservatory is a colonnade about 100 yards long running east, which is continued to the south front of Holland House. By this means a communication, under cover, is opened from the house to the con-

servatory, then to the banquetting-room, then to the loggia, then to the tower, and home either by the flower garden or the pleasure grounds, or by a terrace-walk along the whole length on the top of the colonnade. The flower gardens are seen to advantage when overlooked from the terrace, surrounded by balustrades, on the top of the banquetting-room.

The ground rises on all sides to a beautiful knoll in the park. This knoll is crowned with a most picturesque group of Cedars of Lebanon. Other trees creep up the slopes and form groves around the base and along the valley, not thick groves of gloom, but groves in which the forms of the trees are fully developed, and the trees being planted at various distances apart produce glades of pleasing landscape scenery.

The house is surrounded by pleasure grounds so nicely connected with the park, that a beautiful and varied landscape is produced, bounded by deep shady groves that form the framework of this delightful picture.—W. KEANE.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE December meeting was held on the 6th inst., F. Smith, Esq., the President, being in the chair. Amongst the donations to the library since the November meeting were the publications of the Royal and Linnean Societies, the Royal Physical Society of Edinburgh, the Moscow and Stettin Society, the continuation of Lepp's great work on European Lepidoptera by Snellen Van Vollenhoven, a remarkable memoir by Mr. Edwin Brown on the genus *Acentropus* now proved to be a Lepidopterous insect, articles on farm and garden insects by Mr. Wilson, of Adelaide, &c.

Mr. S. Stevens exhibited a box of Coleopterous insects collected in the Zulu Country, South Africa, by the Rev. M. Girard, including many very rare and interesting species; also, a curious variety of one of the British blue Butterflies, apparently intermediate between *Polymnatus alexis* and *P. adonis*, taken in the Isle of Wight.

General Sir J. B. Hearsey exhibited a case of nocturnal Lepidoptera collected by himself in India, containing many very fine and large species of Geometridæ and Noctuidæ, several of which appeared to be undescribed.

Professor Westwood stated that the Rev. Henry Rowley, one of the clergymen attached to the Oxford and Cambridge Missions to South Africa, had forwarded a small collection of Lepidoptera and Coleoptera from the Zambesi to the Museum at Oxford, containing many rare species, which appeared to be very similar to, if not identical with the insects of Mozambique, collected by Peters, and described by Klug, Schaum, Hagen, &c., in the voyage of that traveller. He also exhibited a remarkable manuscript entomological calendar or journal kept during a long series of years by the late Mr. J. Curtis, containing about two thousand notes and observations on the habits, times of appearance, &c., of insects chiefly injurious to the farm and garden, man, domestic animals, orchard and forest trees, &c.; also, a manuscript report of one of the meetings of the Norfolk and Norwich Entomological Society, held in the year 1812, containing among other entries the admission of the Rev. Mr. Kirby into the Society on his own request. He also exhibited and described two very curious small Beetles captured in the Canary Islands by Mr. Vernon Wollaston, remarkable for the large size of the heads of the males in both species, and forming the types of two new genera.

Mr. W. Wilson Saunders exhibited specimens of a new and very pretty species of *Bryocoris*, a genus of Plant Bugs, which had attacked the leaves of some of his Orchids (especially plants of the genus *Cutasetum*) in the same manner as the Thrips; but being provided with wings and very active they made their escape on the slightest alarm, and flew off to other parts of the hothouse, returning, however, to their food plant after a short time.

Captain Cox sent for exhibition a series of very beautiful representations of Moths and Butterflies, which he had executed by photography, and which represented the most delicate markings of these insects in a very exquisite manner.

Another illustration of the use of photography in the delineation of insects was shown by Mr. W. F. Kirby, in the recently published memoir on the Tryptetidae by Dr.

Loew, in which the elaborate and intricate markings of the wings of these insects were represented of a gigantic size.

The President gave an account of an examination made since the last meeting of the nest of the small Honey Bee of New Holland, obtained from Queensland by Mr. Woodbury, and now belonging to the British Museum. On removing the side of the box in which the nest was built, not fewer than four or five hundred dead working Bees were found. The cells were of an hexagonal form, built into regular combs, and, like those of the common Wasp, with the mouths of the cells downwards. This peculiarity of position, unlike that of the cells of our common hive Bee, was connected with the facts that the cells served only as cradles for the brood, and that the honey was stored in oval cups, or honey-pots, of which there were as many as two hundred and fifty at the foot of the nest, as in our British Humble Bees. Some account was given of the nests of other species of Meliponæ and Trigona, from the writings of Guérin-Ménéville, and Gosse. The material of which the cells and combs were constructed did not appear to be wax, but rather a resinous kind of gum, which, according to Mr. Woodbury, ignites instead of melts, as is the case with common wax.

Mr. Wilson, of Adelaide, South Australia, sent some specimens, accompanied with notes on the habits, of the larva and perfect state of *Calosoma Curtisii*, one of the most beautiful species of the genus, which, unlike our northern species, which are found in Oak trees, was generally met with under crowding.

Mr. McLachlan read some notes of the type specimens of the species of Phrygnæidæ, described by Fabricius, contained in the collection of Sir Joseph Banks, now forming part of the British Museum.

WHICH IS THE BEST WAY OF HEATING BEDS BY HOT-WATER PIPES?

I THINK this subject will be the better of a little ventilation; and, therefore, by your permission, I will place it before your readers, in the hope that some of your practical friends will answer the above question, and give the result of their experience in your pages.

We are all aware that the use of hot-water pipes is intended to dispense with that of manure or other decomposing substances, the object being to raise the temperature of the soil sufficiently to induce seeds to germinate, and to encourage the growth of plants at unnatural seasons. Now what is the best position for the pipes to be placed in connection with the bed which they are intended to heat? How should they be placed so that they may impart the greatest, and at the same time the most equable temperature to the soil of the beds?

The following are the modes generally used by gardeners: First A. This appears the most general.

1 and 1 are walls, between which is constructed a chamber 2, having two hot-water pipes 3, 3, which pass through it without touching top, bottom, or sides; but are intended to heat the chamber sufficiently to impart warmth to the bed 4, which rests upon the flag or slate flooring above the pipes. This method has always appeared to me objectionable because there is a great waste of power. A great amount of heat must be expended on the side walls and vacant space in the chamber. The idea is, that as heat will rise it must pass through the bed. I grant that; but I

fancy that but little remains to rise after the work it has first to do below.

The next method is B, in which 1 1 are the walls, and it may be considered better than A, inasmuch as the action is more direct, but yet liable to a certain consumption of heat by the surrounding air.

C is a nearer approach to direct communication between the pipes and the soil; but a medium in the shape of a bed of broken stones or bricks still stands between them; and it appears to me that they will absorb a considerable proportion of the heat before they will permit any to pass without paying a heavy toll. It may be said that the broken bricks or stones act as drainage for the bed above them; but if this is so, I question whether they would not be more properly placed below the pipes, for in that position they would have a tendency to draw the roots of the plants above to that part of the bed, which, being nearest the pipes, would be the warmest. I, therefore, raise the question whether the best and proper place for the pipes is not through the soil of the bed itself as shown in D.

Here in D we have direct action. Nothing but the soil can absorb the warmth from the pipes. Nothing can retain the imparted heat for so long a period as the heated soil, and we dispense with the agency fee of any intervening medium. This appears to me to be the surest way of making a hotbed; no one would ever think of heating a tank or cistern by running the pipes through a chamber below it instead of through it; I may be told that it might injure the tender roots if they came in contact with the pipes. This I venture to doubt, because in clearing out a bed recently, I noticed that the roots of some plants had struggled to find their way to the warm pipes through a superincumbent mass of rubbish. I have sufficient faith in nature to believe that the roots will not willingly go into danger, and that like the burnt child which dreads the fire, they, if their feelers find

the place too hot to be pleasant, will strike out in another direction; indeed, if they did get singed or burnt by venturing too near to their warm friend, might I not, in these days when root-pruning is the fashionable treatment, be right in assuming that the process by cautery is superior to cutting?—W. W.

ROYAL HORTICULTURAL SOCIETY.—In the conservatory at Kensington there is now suspended a bunch of Bananas of extraordinary size. It was grown by Mr. J. Carr, gardener to P. L. Hinds, Esq., of Byfleet, Surrey, and was produced by a small plant imported from the West Indies in September, 1862. The plant was grown in a tub, and was only 4½ feet high when it bore the bunch, which is itself about 3 feet long, with a stem as thick as a man's wrist, the whole weighing 86 lbs. As yet only the fruits at the base of the bunch are ripe, those at the opposite extremity or further from the plant when growing, are as yet green. We believe it is intended for presentation to Her Majesty.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The various operations of draining, trenching, and digging, to be carried on with vigour, and the ground if naturally heavy to be laid in ridges. When frosts occur the ground that has been ridged would be benefited by turning over the ridges with a fork, and if deeply frozen, with a mattock, the more fully to admit pulverising and vermin-destroying action to all parts of it. The planting of vegetable crops should now be merely confined to a few sorts of Cabbages, Coleworts, and late Celery for soups. The hoe may be used occasionally in dry weather with advantage, to destroy weeds between the rows of vegetables, and to draw earth to the stems of Cabbages, &c. The *Potato Onion* is a most productive crop. The small offsets to be planted in beds 4 feet wide, four lines (not drills) to be drawn 10 inches apart on the beds, the offsets to be placed upright, slightly pressed into the soil, and covered with an inch or two of leaf mould, or any light soil; when they appear above ground, to be earthed-up on a fine day. They will be ready to take up in the latter end of June to succeed the August-sown ones for use. A dressing of fresh loam is, in many cases, preferable to manure for land that has been long cropped with vegetables, and where it is wanted and can be obtained, it should be made ready in order that advantage may be taken of frosty weather for heavy wheeling. Where fresh soil cannot be obtained, charred vegetable refuse, such as prunings of shrubberies, edgings of turf, and many other things that may be collected for the purpose, will form an excellent substitute, and there are but few gardens that would not be improved by a dressing of charred vegetable matter.

FLOWER GARDEN.

The work of the flower garden and of the pleasure ground will now consist in finishing, if mild weather continue, the planting of shrubs, trees, bulbous roots, and hardy perennials and biennials. Complete the planting of Roses, if not done already, and if there is not sufficient time for trenching the ground 2 feet deep, a large hole of that depth to be made and filled up with some good loam and well-rotted horsedung. Be careful when planting that the stem is not buried too deeply, as a trifle lower than the depth it was planted before will be sufficient; the roots to be spread out regularly, and when covering them the soil to be pressed around them gently with the foot, then stake to prevent the wind from loosening the plants at the neck. If the budding of Roses is intended in July, the stocks should be procured and planted while mild weather lasts, the brown-backed to be selected in preference to the green-backed; plants of the China or other tender varieties to have a little moss tied round them for protection from frosts. If there is any other tree, shrub, or plant that the experience of past seasons has proved to be susceptible of injury from frosts or the inclemency of the winter weather it should be protected in good time. Hoing and raking the borders amongst shrubs will be sufficient to give them a clean and neat appearance without the use of the spade, to which we

have a great objection, as it cuts the fibrous roots and weakens the growth of shrubs that were planted to be ornamental for pleasure-ground scenery.

FRUIT GARDEN.

Although we consider November the best month for planting fruit trees, if through any of the many causes of delay such operations were not carried into execution, we would strongly advise all to set about such work as soon as possible, and to finish it while open weather lasts. If only an improvement in the soil is thought necessary, loam and leaf mould are the best for the purpose, and as a makeshift for drainage to raise it as much as possible where the trees are to be planted. When transplanting, the trees to be taken up with care, any broken, bruised, or long straggling roots to be pruned with a clean cut, and when planting to comb them with the fingers to spread them regularly in the holes, which are to be of moderate depth, and of more than sufficient width for the extent of the roots. The fresh soil to be shaken over them carefully, and gently pressed down (not stamping with the feet) all round, the trees to be then watered and mulched, trained to the wall or espaliers, or if standards, to be firmly staked. Make a point of examining every week all choice fruits that are approaching ripeness, or are found not to be keeping well, so that everything may be used at the proper time, for some of our best Pears are worthless enough if allowed to get over-ripe before using, and the same is the case with many varieties of Apples. Also, look over the whole stock when time can be spared, removing any that exhibit symptoms of decay, and putting them aside for immediate use.

GREENHOUSE AND CONSERVATORY.

Give air freely, but not in currents, when the weather permits; use water very sparingly, always tepid; apply fire heat occasionally in the day, with free air to dry up damp. Chinese Azaleas and Camellias to be kept cool, the forward plants to be pushed on with a little heat to expand their flowers properly. Shift on Calceolarias and Cinerarias. Supply water to the Heaths and New Holland plants that are coming into flower more liberally than to the others. Assist the early Pelargoniums with a little heat, but keep the summer plants cool and airy. Keep Chinese Primroses near the light and air, and water cautiously. Orange trees or any other plants that have not been recently potted to be fresh surfaced, by removing a little of the top soil and supplying its place with fresh. When the Chrysanthemums begin to fade they may be removed to the north side of a wall, the pots plunged in old tan, leaves, or sawdust, to protect them from the severity of winter.

PITS AND FRAMES.

Plants in these structures to be kept as dormant as possible, with the admission of air at all favourable opportunities, and a little quicklime carefully sprinkled round the pots to absorb moisture, and in some measure thereby to prevent them from fogging-off. If a severe frost sets in, when it will be necessary to cover them up to the exclusion of light and air for some days, when a change in the weather takes place, the precaution of shading them for a few days should be taken to inure them gradually to the glare of sunlight. Means of protection should now be ready, for if postponed until a sharp frost sets in, all will be hurry and confusion, and the labour of months and the hopes of a rich display next season may be destroyed in one night.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

ONE of the great difficulties connected with gardening in England is to be found in the extreme changeableness of the weather. Many a man who attends to these changes will prove himself a good gardener, though knowing but little of science. Many a man with the knowledge of a philosopher will fall into trouble because such little matters are beneath his attention. We shall never forget a gardener coming into a lodge of young gardeners, with bull's-eye lantern in hand, and asking a clever fellow, absorbed in the pages of a thrilling romance, "Why is it there is no fire in the conservatory?" "Is there any frost, sir?" "Well, I did imagine you had something in the way of eyes, hands,

and feet!" Just fancy, a mild day, and now a little before ten at night a very sharp frost, the waterbutts covered with an inch of ice, and the poor fellow tearing about and up half the night to make the conservatory safe, and no thanks, but the reverse, for all his trouble. The use of his eyes early in the evening might have saved him all the night work, allowed him to dream pleasantly of the charming heroine of the novel, and enabled him to have escaped a scolding, which was a mere trifle to the want of confidence thus engendered.

These sudden changes involve not only the exercise of attention, but also a considerable amount of extra labour to secure the means of safety. We have lately had some beautiful dry weather, with a barometer too high to expect much frost or snow. On Tuesday morning the glass fell a little, and we had a smart rain, too much for out-door labour, and we had just made preparations for having ainery washed and cleaned when down came a heavy shower of snow, and shortly afterwards the glass moved up a little, the sky became clear, the sun shone brightly, and out of the sun the ground was frozen the whole of the afternoon. From the vagaries of the thermometer we had no idea of a continued frost, but still there was a chance of a sharp frost for that night, and, therefore, everything tender was protected. We were convinced by the time the sun was set that the frost would not continue, from the yellowish cast of the sky, and later, from a halo round the moon and the veering of the wind to the west—circumstances which, if they had taken place sooner, might have induced us to have used less protection, and more especially as the moon being about the full there was more chance of the air being clearer in the evening than in the morning. We were not surprised that there was a considerable change in the morning, permitting of everything being uncovered early. But suppose we had covered none, there are many things that with mere glass protection would have given us no more trouble, except moving them to the rubbish-heap. The only benefit we derived from noting the changes was using only a little fire heat, instead of a strong fire, which might have been given if these changes had not been noted; and being convinced more still if that were necessary, that for merely keeping out frost from small places nothing is so economical as a small stove inside the house. The weather has been first-rate for wheeling, and, therefore, the kitchen garden has had a fair dressing of burnt earth, and what manure and materials could be spared from the rubbish-heap. In dry weather at this season it is better to wheel than on mornings which are frosty, as the wheel moves much more easily and gets no incrustation, and even on lawns there is less of marking left. We have noticed that grass wheeled over when very frosty afterwards looks as if it had been charred, and the marks remain a long time.

We have found our compost-heap consisting chiefly of the clearings from the flower garden, a few tree leaves, and a little horse-litter most useful. They were thrown up, well mixed, and the decayed flowers of *Calceolarias*, *Verbenas*, &c., gave enough of moisture to cause the whole to heat nicely, and yet to keep bulk well, and that without any turning. The whole has been used for making up a bed for a frame in which Early Ash-leaved Potatoes have been planted, also, for another bed for early Carrots; and a deep earth pit has been filled and planted with Potatoes, as we can lay old sashes across it. The soil employed is that which has been used for Melons and Cucumbers, a little slaked lime and leaf mould being added. About 5 inches of soil is placed on the bed, the started Potatoes placed in rows, and 5 or 6 inches of soil placed over them. Sometimes this is left in ridge form, but, as in the frame, more generally flat, in order that Radishes may be sown between the rows. In planting, unless the Potatoes have been forwarded in small pots, which is a capital plan to make them tuber early, it is as well for the shoots of the sets not to be sprung more than 1 inch, as when larger and the roots are freely growing they are apt to receive a check. Planted out also some in pots, two sets in 16-sized pots, about 8 inches in diameter, and placed them in a pit where a little dry heat could be given as well as a mild bottom heat. We have had them good at Christmas by this mode, and one advantage of having them in pots is, that they can be moved and placed under a little protection as soon as the tubers are full grown.

Placed, also, a number of sets in 48-sized pots. When the stems attain some size the pots and part of the stems will be plunged in a slight hotbed or leaf mould. The confinement of the roots causes tubers to form more quickly than where more room is given. We find that all these things do better after the shortest day has passed than before; and, therefore, a week or two at this season is not of so much consequence. To have nice new Potatoes at Christmas, the sets of early Potatoes should be kept well greened in a sunny spot in summer, and planted in the end of September. Then the young Potatoes will be good. Those who are fond of young waxy Potatoes may have them easily all the winter with much less trouble. For instance: save a lot of the crop of 1862 over 1864, pick them of all sprouts in spring, and keep the tubers as dry and cool as possible over the summer. In September and onwards place these old tubers in rather dry soil, leaf mould, &c., in a dry place, put them in layers, covering all over with some 6 inches of soil, and during the winter, though a single stem never appears, very fair-sized waxy tubers may be obtained. We have frequently passed them off as early Potatoes, and they have been approved of because they were new Potatoes, though possessing but few of the best qualities of early Potatoes grown in a frame or a pit, with the foliage exposed to sun and air in the usual way.

Sowed Radishes also over the Carrot-bed. We know of nothing more economical than a two-light early Carrot-bed, the Carrots are so nice, and the Radishes are all gone before the Carrots have grown to any size. The Radishes should not be thick, and if the Carrots are thinned chiefly by pulling the largest for use, there seems to be no end of gathering. Gave plenty of air in favourable weather to early Radishes, Lettuces, and also to old Lettuces, Endive, &c. Sowed a few more Kidney Beans, and among them a few of the Newington to be cooked whole if it is so desired. Packed-up Artichokes, Celery, and run a layer of burnt earth and charred rubbish along the sides of Cabbages and autumn-planted Savoys. Placed, also, a little of the same, and some rotten dung over Asparagus for the winter rains to wash through, and proceeded with digging, trenching, &c., as the work could be done. For Mushrooms, Sea-kale, &c., see last and previous weeks.

FRUIT GARDEN.

Looked over bunches of Grapes, as one berry going will soon give you three or four, and they will soon make a wreck of the bunch. To prevent damp put a little fire heat on every morning with air, and in mild weather allowed it to go out in the afternoon. Generally leave a little air at back unless when frosty. Prepared for clearing and washing middleinery on a wet morning, but left it as the weather became fine. Some of the Vines from excessive cropping for many years have become a little weak, and we have placed four young Vines by the side of the old ones, after removing carefully a portion of the old soil and furnishing with fresh for the young plants. This is a sort of makeshift, but when the old plants can be better spared (and the young ones, if not quite to our mind), they can be raised and a fresh border given to them. These Vines are all planted outside and brought through holes in the front wall, and we cannot help it without changing the whole interior arrangements. Partly from the twist that must thus be given to the stems, there has been a tendency in the latter to throw out humps of cellular matter, and that we think has encouraged the mibbling of mice, and these as well as the excessive crops have lessened the usual vigour of the Vines. The pieces of fresh soil will also encourage the old Vines, and by rearing some strong Vines in pots, we will make sure of doing all fresh next season if not fully satisfied with the makeshift. We watered the roots of these Vines, as soon as laid out and covered, with warm water. Used soil in a nice, friable, mellow state, and covered the ground with a foot of hot leaves, and a covering to keep dry over all, so that the roots will be a little excited before the tops receive any heat, some six weeks hence. Turned over the litter on the border of a firstinery, placing about 6 inches of leaves, a little warm, next the soil, and the old on the top, making in all about 15 inches. The heat in the border a few inches from the top was about 60°, and these few leaves will raise it we think to nearly 70°. At a foot beneath the

surface it will be from 55° to 60°, and in a week or so we will start with a little fire heat.

Figs in the house we are keeping cool and rather dry, and will not prune until growth commences. Every available inch beneath them is covered with bedding plants. We will move some Fig trees in pots, and most likely a few Peach trees in pots into the first vinery; and if there should be any vacancy from planting young Vines, the place can be filled up with Vines in pots. A number of these that have been plunged for some time in a mild heat in an earth pit have been plunged again after the bed was turned, a bank of horse-droppings placed inside in front of the pit, and glass sashes laid across, and but little air given. The insects must have a wonderful constitution if they escape the steams from the horse-droppings. As these Vines come forward a bit we will remove them to where they can have a dry heat. Kept moistening the Vines in pit, which seem to be beginning to move, the place beneath being supplied with Dwarf Kidney Beans in bloom and swelling. Another pit which is 6 feet in width, with a smaller pit in front for Cucumbers, Melons, &c., stands well for the sun; and there is a shelf at the back on which Black Prince Strawberries are placed. Between the back wall and the narrow pit in front is a narrow pathway. We wanted to have three or four rows of Strawberries in front of those on the shelf over the pathway and the bed. And now, to manage it in the easiest way. Some old larch poles were found. These were cut so as to go across from wall to wall on the same slope as the glass, and about 16 inches from it, the end of the poles being sloped likewise, so that as they pressed against the wall the more weight placed on them the firmer they would be. These poles formed the rafters for temporary shelves laid longitudinally across them, and a small wedge of wood placed on the pole in front of the shelf would keep it level. These poles, the shelves being removed, may be taken away in a few minutes to form the groundwork for a stage in any other pit of a similar size; and thus Strawberries and anything else may be brought as near the glass as it is desirable. In the present case, as we will only use three or four shelves at present, the pit will continue to be filled with other things. We do not think of any more simple plan at present; and we allude to it more prominently, as an inquiry has been made whether such a pit might not be filled with leaves to the requisite height and slope, and the Strawberry-pots set or plunged in the leaves. We say No, for two reasons. First, by our plan, the pit being heated, there will be a greater circulation and a greater body of air about the plants; and secondly, because when Strawberry-pots are kept plunged at this season they grow too much to foliage. Even in such a professed bed of leaves we would prefer the pots to stand on boards. Those we have set on shelves (temporary ones), have been brought from a frame in which they have stood a few weeks, as noticed last week; and there is nothing between the bottom of the pots and the board but a little moss. It is not likely they will fruit there; but if they did, the pots would be thinned, and a little leaf mould placed over the moss, or most likely a thin piece of turf with the earthy side upwards, would be used instead of either.

Proceeded with pruning, nailing, &c., as opportunity offered. Put in cuttings of Cucumbers, and sowed a few seeds; as several times stated, the leaves of those bearing now cannot have too much light. The temperature at night should be moderate, not to excite them too much—say about 60°; and it is important where length of fruitfulness is desirable that the plants should be allowed to fruit sparingly; one fruit now will be more exhausting than four after the middle of March. Where Melons are wanted early, seeds should now be sown.

ORNAMENTAL DEPARTMENT.

See last and previous weeks, and Mr. Keane's specific directions as to stove, forcing-pit, &c. Where you have plenty of room large lumps of Lily of the Valley may be placed on the floor of a forcing-house; but if you want very fine pots you must disentangle the roots, and use only plants having nice, firm, plump buds, and cram these closely together. These will do in any forcing-house; but they will do better if you can give them a little bottom heat for a few weeks, whilst the buds are kept rather cool. With bedding plants, where there is no fire heat, the great enemy

will be damp, and the Verbenas and the finer Geraniums will be the first to show it. Calceolarias will stand a good portion, and seem to like it; nevertheless, after the frost of Tuesday, we had all the lights off on Wednesday, in order that plants and surface soil might be well dried, as, in such changeable weather, it behoves us to be prepared for a continued frost, whether it come or not. All plants in windows should be watered sparingly; and our friends will be pleased to recollect that every bulb they use for window or room decoration will bloom better by having made abundance of roots before the leaves or the flower-stems appear. No place is better for starting Hyacinths, &c., for glasses or pots than a dark cool closet. The more the vessels are filled with roots before the stem appears the better will the bloom be.—R. F.

COVENT GARDEN MARKET.—DEC. 26.

The great market of the week was on Christmas eve, when a brisk trade was done, but the supply being equal to the requirements of the season, prices were not affected. To-day, though there is plenty of everything, but little is done in the way of business. Hothouse Grapes are rather more scarce, and in Apples and Pears no fresh varieties have made their appearance; indeed, owing to the early ripening of the late kinds, such as *Beurré Rance*, *Ne Plus Meuris*, and *Easter Beurré*, these are now fit for use, and after they fall Pears may be considered as over. Cut flowers are plentiful and meet with a ready sale. *Pelargoniums*, *Orchids*, *Acaecias*, *Camellias*, *Chinese Primulas*, *Early Tulips*, *Roses*, *Violets*, and *Mignonette*, are the principal.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 162, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

PRICKLY PEAR SEED (Lar).—Fill some pots three parts full of crocks or broken pots, and over them place an inch of sandy loam, one-half of which should be pieces of pot the size of pigeon beans or peas. Sow the seeds and cover lightly, not more than the diameter of the seeds, with sand. Place in a gentle heat, and be careful not to water often, as it is necessary to keep the soil moderately moist. When the seedlings are fairly up remove them to the greenhouse, and keep them near the glass with the full sun over them. They will require moderate waterings during summer, always taking care to keep the soil dry rather than wet; but moderate moisture suits them best. In winter they need no water beyond a little occasionally in bright weather to keep them from shrivelling. When the seedlings are sufficiently large to handle pot singly into small pots, using a compost of sandy loam half, and broken pots and pieces of charcoal the size of a hazel nut the other half. The drainage should occupy one-third of the depth of the pot, and if the pot is double the diameter of the plant it is a proper size. After the plants become established, standing them out of doors in a sunny situation from June to September is better than keeping them continually under glass. A temperature ranging from 45° to 50° suits them in winter. They are very easily cultivated, all the care needed is to prevent the soil becoming sodden about them, which causes the roots to decay, and rots the stem. We should like to know if any one has succeeded in obtaining from this plant (*Opuntia vulgaris*) fruit in this country worth anything and under what treatment. Ours were always insipid.

AMARYLLIS CULTURE (*A. S. D. G.*).—Your treatment is all right so far; and now if you could plunge the pots in a bottom heat of 75°, keeping the atmosphere 10° lower for a fortnight, you would have no trouble in bringing the roots to the sides of the pots, providing the soil was kept moderately moist. After that they should be kept in a temperature of 60° by night, with a rise of 15° with sun and air. Water freely until the leaves attain their full size, then gradually withhold the water, and give three months of rest at the dull period of the year. Amaryllis Johnsoni, A. Johnsoni major, and A. Prince of Orange require the above treatment. A. longifolia Rosei does not require so much heat as the others, neither does the Jacobaea Lily. A rather warm greenhouse is the best place to winter them in; and a vinery is very suitable when growing. In other respects they all require the same treatment. We are promised an article on the cultivation of this family.

CINERARIAS FROSTED (*G. S., Dalkeith*).—Your Cinerarias will certainly be injured in their flowering by becoming frozen. Keep them near the glass, and give abundance of air, thus encouraging sturdy growth. They may possibly recover so as to flower well, though not so well as if they had not been injured.

HELIOTROPES FOR WINTER (*Idem*).—For this purpose we prefer plants which have been struck in spring and grown on during the summer, as you propose doing with seedlings. Cuttings flower more freely than seedlings, and on that score alone we prefer them. Seedlings, however, do moderately well for winter blooming, and are stronger and not so liable to damp off. At the same time they are shy bloomers, and are not always worth growing. Cuttings struck in March will better answer your purpose. All they need is frequent repotting, and pinching back the shoots in order to make them shapely. The blooms should also be nipped off during the summer until September. After that they will flower freely if kept in a warm greenhouse.

PLANS OF FLOWED GARDENS (*C. B.*).—There are no plans of gardens published in a separate form. There are a hundred spread through the volumes of this Journal.

TREES TO REPLACE CHESTNUTS ON A DRY SOIL (*E. Hicks*).—We should think the dry rocky soil you describe would grow Walnut trees, which are both handsome and useful, though by no means the most proper by a public road. The common white flowered Acacia would also look well, and we are not certain but a Birch would do well in such a place, though not better than a Beech, and if you liked to have the purple-leaved one it would do. Most of the newly introduced trees are of the Pinus tribe, and as you object to evergreens, they are not admissible, and it would not be advisable to plant any but robust-growing trees of known hardiness. If you wanted three trees differing widely from each other, and at the same time ornamental, plant a white-flowered Acacia, a scarlet-flowered Horse Chestnut, and a purple-leaved Beech. They are all hardly fast-growing trees. It would, however, be advisable to exchange some of the soil which the roots of the late trees have been occupying for other fresh soil before planting anything.

HALDY ENIGRENS (*A. J. G.*).—The commonly-called Alaternus, is in the *Cottage Gardeners' Dictionary*, under the botanical name, *Rhamnus alaternus*. *Griselinia lucida* or *littoralis* is a plant introduced since the *Cottage Gardeners' Dictionary* was stereotyped, but will be found in the "Supplement" about to be published. *Eugenia Ugni* was supposed when first introduced to be tender, but in most situations it is now found to be hardy, and the same observation applies to the other two plants you mention.

VARIOUS (*C. T. H., Dorset*).—There is no better *Tropaeolum* than *elegans* in its own shade of colour; brilliant is darker but not better; *Tom Thumb* (yellow), is fine; and so is *Pearl*, but the flowers are large like a common *Nasturtium*. We know *Pinus insignis* will certainly succeed near the seacoast, and we know of no reason why *P. austriaca* should not do so.

INSECT ON LAUREL LEAVES (*H. F. Hamilton*).—We are not aware of any insect which gnaws the leaves of the Laurel. Possibly the mischief is done during the night, and the culprit might be caught by examining the trees with a candle after dark.—W.

ALANANDA NERIOLIA TREATMENT (*A South-Eastern Subscriber*).—Keep the plant dry at the root, giving no water except a little occasionally to keep the stems fresh. From now to the middle of March it will do well in a temperature of 45° to 50°, providing the atmosphere be kept dry. In March cut out the weakest shoots and prune the strongest back about half their length if it is a young plant, but if it is large and the wood well ripened, the shoots may safely be cut back to the second joint. About a fortnight before this or the beginning of March, repot the plant, taking away as much of the old soil as can conveniently be done without injuring the roots. Drain well and use a compost of turfy loam half, leaf soil one-fourth, and well-rotted manure one-fourth, with a liberal admixture of sharp sand. If the plant is young omit the manure, supplying its place with turfy loam. When the plant shows signs of growing out it in as mentioned before, and be rather sparing of water until growth fairly commences, when liberal waterings are required. Abundance of light and air, with copious syringings are requisite. After February the temperature should range from 50° to 70°. This plant is the hardest of the Alanandas, and deserves more extended cultivation on account of its giving a colour much wanted for effect in conservatory decoration in summer and autumn.

CISSUS DISCOLOR (*Idem*).—You are quite right in keeping dry at the root. Continue to do so until March, but do not allow the stems to shrivel through excessive dryness. Water must be given to prevent this, and it is wonderful how little is necessary to do it. Pot in March, and place in gentle bottom heat if you have it, and you will be surprised how kindly the buds break in comparison to those not so stimulated. It requires a temperature of 55° to 65° in winter, and from 60° to 80° when growing.

CINERARIA LEAVES CURLED (*A Subscriber, York*).—The leaves curl through a contraction of their tissues, which is mostly caused by insects sucking out the juices of the leaves; but keeping the atmosphere too dry induces hasty evaporation from the leaves, and this causes them to curl up. Too high a temperature at this season is also the cause of the leaves curling, for it induces growth at a time when there is not sufficient light to perfect the growths made. Give abundance of air, keep near the glass, and discontinue the regular watering, giving water only when the plants need it; but do not let the leaves flag from want of it. Do not water, however, until they need it, then give enough to run through the pots. See that the drainage is all right, and watch narrowly for the appearance of the green fly. We think the curled leaves would then improve after the day lengthens.

ARRANGEMENT AND PLANTING OF VINERIES (*A Dumbartonshire Youth*).—Your arrangements are very good. You will have plenty of heat in the late house, and so you will in the early one, if you do not commence until January, especially if you take two pipes round the end next the boiler. If you think of beginning earlier, you had better have two pipes at the other end likewise. We would plant as follows, according to your own selection:—*Early House*.—Prolifer Sweetwater, Black Hamburgh, Rowood Muscat, Mill Hill Hamburgh, Canon Hall Muscat, Muscat of Alexandria and Damas Violet. *For Late House*.—Victoria Hamburgh, Muscat Hamburgh, Royal Muscadine, Lady Downes', Chasselas Musquet, and Black Prince.

NAMES OF PLANTS (*Violet*).—No. 1, is one of the Holly-leaved pinnate Berberies, probably *B. repens*; 2, is some *Passiflora*, it is impossible to say which from a single starved leaf. (*T. P.*).—1, *Epacris purpurascens*. The others are garden varieties which you can much better name at the nearest nursery than we can without a collection of the plants at hand for comparison. 2 has the features of *E. grandiflora*; 3 and 4, of *E. impressa*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

RELATIVE ENTRIES—BIRMINGHAM SHOW.

THE various reports of the great congress of poultry seem to prove that this Show has been eminently successful. True, there has been a very unexpected exhibition on the part of one of the Judges—one, which possibly will yet form the subject of further steps. Our "old mother" would appear to fancy herself "perfection." She, certainly, has been most successful; but, as certainly, I would take exception to the opening paragraph of the "Regulations," "No additional prizes or medals will be awarded, the extended classification now adopted rendering any departure from the prize list in this respect unnecessary." The italics are mine.

Now, in the analysis of the relative entries at this monster Show, a difficulty arises at the outset. The method of entering is peculiar, but for practical purposes I have assumed each entry to be 7s. 6d.; and with this assumption as being equally fair to all breeds, I think I shall be able to prove that a "departure from the prize list," if "unnecessary," would be fairer than at present.

The Show has proved that Black Hamburgs richly deserve and thoroughly support a class of their own; but it has shown almost as unmistakably that the "degenerate Poles," or, in other words, "Crève Coeurs," do not deserve a class, and this experience tallies with the entries at Worcester, where also they enjoyed a class to themselves. I do not fancy they will ever become great favourites on this side of the water.

I place the various breeds according to their value as returners of money to the coffers of the Show, and will then add a few remarks.

Order of Merit.	Breed.	No. of P. us.	Prizes offered.	Amount received for Entries at 7s. 6d. each.
1	Dorking	269	£63	£109 7 6
2	Cochins	205	62	76 15 6
3	Hamburgs (Spanish and Penedel)	199	72	74 12 6
4	Game	330	129	131 7 6
5	Brahmas	34	15	12 15 0
6	Bantams	115	48	45 2 6
7	Black Hamburgs	23	10	8 12 6
8	Spanish	71	34	26 12 6
9	Polands	47	59	17 12 6
10	Malays	10	10	5 15 0
11	Crève Coeurs	7	10	2 12 6

It is evident from these figures that if the Judges had had power to award additional prizes, the Dorkings most richly deserved it. I have never shown, and probably never shall show this breed. I, therefore, cannot be accused of partiality here; but every unprejudiced eye must see at a glance that this breed deserves still greater encouragement at Birmingham. This might be done either by intermediate prizes of £1 10s., £3 10s., &c., or by making a number of prizes of the same amount, the honour of being third or fourth being all the difference. If the Committee simply acknowledge the justice of these remarks, they may work the remedy in any way they think best.

No. 2 and No. 4 I will consider together. They have this in common that private individuals added cups of value, and thus increased, we may suppose, the competition. These amounts I have not added to the prizes offered. Were I to add it, Hamburgs would then become second, and Brahmas fourth, in order of payers. Both Game and Cochins were well encouraged at Birmingham, and they have responded

fairly. The Brahmas scarcely return their amount. They are not treated as they should be, and accordingly the catalogue does not contain the names of several successful breeders—Messrs. Priest, Wright, Hinton, and Pigeon, for instance, are absent. Possibly they feel as I do, that the Brahmas do not receive sufficient encouragement. Taking 1863 as my guide, they pay Birmingham vastly better than Spanish, yet they have only two prizes in each class. The two varieties compete together, so that the light birds are almost excluded from the prize list. They might be allowed a "two hens or pullets" class, or a "cock and one hen," and the Committee, I firmly believe, would be the gainers. The amount offered to Polands is greatly beyond their returns. One of the prizes in each class might be saved.

What shall I say of Malays? The returns are pitiful, and yet who would wish them excluded? Would the Show be perfect without them? I would suggest dividing the amount into three prizes instead of two; the fact being, that these prizes are gained chiefly either by Mr. Ballance or Mr. Sykes, whose birds are most decidedly of very different strains, and their relative positions dependant on the Judges selected. Possibly, then, others might also notice this noble breed.

The Crève Cœur makes a still more piteous appearance than the Malays. My slight experience of them is not in their favour, and one breeder who had been tolerably successful with them has parted with his, or was anxious to do so. I repeat that they do not appear to me likely to take much hold on English breeders. Time will show. Meanwhile, their entries at Worcester and Birmingham prove they do not at present merit a class to themselves.

I hope to forward you my analysis of Darlington in the course of a few days.—Y. B. A. Z.

P.S.—I thought experience had proved that it was unwise to show two "Game ladies" together. Hence shows adopted "cock and one hen" classes. Then why classes for two hens or pullets?

CAPTAIN HEATON, MR. HINDSON, AND THE BIRMINGHAM SHOW.

WITH reference to certain letters which have appeared in THE JOURNAL OF HORTICULTURE, stating that Captain Heaton and others were admitted into the poultry bay at Bingley Hall during the time the Judges were making their awards, we are informed by the Secretary that such was not the case, no person whatever being admitted to this part of the building until after the Judges had completed their duties. Captain Heaton did not enter Bingley Hall, until some time after the Judges had given in their awards in the Cochins classes.

[The above has been sent to us by the Council of the Birmingham Cattle and Poultry Show; and Mr. Lythall, the Secretary, adds, that Mr. J. H. Williams, in whose name Mr. Hindson's Game fowls were exhibited, is the Mayor of Welshpool. We never suspected Capt. Heaton of influencing the Judges in their decisions; but the complaint made is, that he and others were admitted into the poultry department in direct violation of the Society's rule 17, and especially of that part which precludes the public from being present whilst any part of the judging is proceeding.]

With regard to the Mayor of Welshpool, he appears to be the guilty party in exhibiting falsely another person's Game fowls as his own; and, if so, we agree with Mr. Hindson in thinking that "his situation in life should have made him above such a scandalous action."

I HAD quite made up my mind not to reply to any more anonymous correspondence; for I have but a poor opinion of a man who attacks another under the protection of an assumed name; but I think the letter of Mr. Manning requires an answer from me—first, because he tells me in a straightforward manner that he considers I have committed an error; and, secondly, because he imagines that I wilfully broke one of the regulations of the Birmingham Show. To justify my conduct with the public, and to prove that the Birmingham Committee never attempted to show any favour towards me, I beg to state the circumstances under which I viewed the poultry on the Saturday evening exactly as

they happened; and I trust, by so doing, I shall convince your readers that I am not the dreadful culprit that some would have them believe.

I was one of those who paid 10s. to see the cattle judged. About six o'clock (the Judges having completed their awards), whilst I was talking to one of the Committee, I heard him give an order to the policeman in charge of the entrance to the poultry department to admit all who wished to look at the fowls. I saw numbers enter the room; and, having heard a distinct order given from one in authority, I did not consider (nor do I now), that I was breaking any rule, or taking an unfair advantage of others in following those who had gone before me. The order from the Committee did not emanate from any request of mine. It is not my intention to reply to the remarks of my poetical friend "SMALL FRY;" for, were I to do so, I should widen the breach rather than heal it. I must now leave you and your readers to decide if I am guilty of the faults laid to my charge.—HENRY HEATON.

I AM obliged for the insertion of my letter, and also Mr. Smith's, refuting the charge insinuated in a previous article on the Birmingham Show. Unfortunately, however, your concluding commentary would seem to imply that there was collusion of some nature; and from this I can scarcely think you have given either of the letters inserted an attentive perusal. You say, "It is unfortunate Mr. Hindson did not announce his discovery until after one of the public had detected the fact." This is met by the assertion in my letter that I was the first to make, as well as the first to announce, the discovery that the birds were my own and exhibited without my knowledge or consent, and this assertion is corroborated by Mr. Smith in his letter. Surely such a satisfactory statement, so respectfully and emphatically verified, should have protected me from any implied aspersion? As to who Mr. Williams is, I can only give you hearsay information, as I am unacquainted with this person, and have no desire to cultivate an intimacy with him; but I am told he either now holds, or has held, the position of Mayor of Welshpool. I trust this rejoinder will clear all doubts upon the subject.—JOSEPH HINDSON, *Barton House, near Liverpool.*

THAT the awards to three of the pens of Game fowls at Birmingham this year have caused more astonishment and animalversion than all the others put together will be acknowledged by those amateurs present at Bingley Hall on November 30th, and probably by hearsay from many others who had not the opportunity of then seeing them. One fact connected with this case seems now quite overlooked, but at the time it was not only a most prominent one, but such also as in the opinion of those present threw a strong light on the subject. It, however, still remains unexplained—all three of these Game cocks in the afterwards "disqualified" pens were marked alike in the nostrils, and, after the most careful examination by a host of amateurs of every other pen containing a Game cock throughout the whole Show, there proved not a single cock among the others similarly marked. It seems, at least, on the first blush of the thing, as somewhat remarkable that a fact so obvious to strangers in these three fowls, should be quite passed over without instant detection by Mr. Hindson their owner. Perhaps, therefore, that gentleman will explain this for the benefit of a poultry amateur who never yet exhibited a—GAME COCK.

IN the last Number of your Journal you say it is to be regretted that Mr. Hindson did not declare the birds to be his before the fact was discovered by one of the public. I should readily admit the force of this remark if it were true. But is it true? You do not say when the discovery you refer to was made; but unless it was previous to the opening of the Show on the Monday morning, it was not before Mr. Hindson had supplied the information upon which these pens were disqualified. It is true some little delay occurred before there was a public announcement that the prizes had been cancelled; but as this delay was not occasioned by any hesitation or reluctance on the part of

Mr. Hindson, it is rather hard that it should be made the ground of an inference against him.

Your inquiries about Mr. Williams I am quite unable to answer. I neither know who he is nor by what means he became possessed of these fowls. I should, however, be surprised to learn that there is any truth in the report you refer to—that he is a person under the control of Mr. Hindson; and, until some proof is produced on this point, I must take the liberty of disbelieving that such is the case.

But let this be as it may, the real vital question is—Were these fowls sent to Birmingham with Mr. Hindson's knowledge or consent? If it can be proved they were, I should be the first to admit that no defence, or even extenuation, is possible; but if, as I believe, they were obtained from the person who had charge of them without Mr. Hindson's authority, the imputations cast upon him are unjust, and ought to be retracted.

I never saw Mr. Hindson until I met him at Birmingham, and I have no motive, except a regard for what is just and fair, in offering my testimony on his behalf.

I believe he performed his duties with ability and conscientiousness; but I declare my conviction that he is free from all reproach in this matter, because what I know of his conduct in reference to these prizes is entirely inconsistent with any other supposition.—J. H. SMITH.

MANCHESTER EXHIBITION OF POULTRY.

THE Poultry Show at Manchester being one of the last if not the very last show of the kind that takes place in the year, is always looked forward to with great interest by exhibitors. This year it formed no exception to those previously held, for not only was there a good general competition, but certainly the attendance of amateurs was also numerically strong. A great feature of the Poultry Show thus annually held at the Belle Vue Zoological Gardens is this, the proprietors never leave anything connected with their exhibition to be carried out by others, unless under their own immediate supervision, and it is but common justice to add, that nearly the whole of the actual labour is cheerfully undertaken by the Messrs. Jennison, as a task to be personally fulfilled. To this very cause may be attributed no small amount of the Manchester Show's success, and the absence of most of those errors that oftentimes arise in those instances where such matters fall only into the hands of underlings. It is known to many of our readers that the large hall in connection with this establishment is appropriated for the time being entirely to the purposes of the Poultry Show. A more commodious and well-lighted edifice for a poultry exhibition could not be devised than the one referred to; and it is well just to name, that by no means the least advantage is the fact, that the whole is properly heated in case of any sudden requirement, as was the case this year the first day, from stress of weather. A Dog Show is held simultaneously, and the care bestowed on this department is equally worthy of commendation, though, perhaps, somewhat digressive from matters connected with poultry. On the morning at an early hour, before the Judges awarded the premiums to the dogs, every dog was carefully permitted to exercise itself in the open air under the care of an appointed attendant, which the dogs evidently much enjoyed, and thus when the Arbitrators proceeded to their duties the animals seemed far more comfortable and at home than we usually find with dogs when first tethered in strange places. Their rooms were also properly heated. It is these little acts of attention that tend so much to make shows of any description successful, and we proceed at once to notice the poultry particularly.

The Silver-Grey *Dorkings* were certainly not nearly so good as might have been fairly anticipated: in the class for adults there being not a pen to be called a really good one—so much so, that the Judges must have strained their forbearance considerably to award the prizes at all. We admit the first-prize pen to be the best of them; but really their condition was the very opposite of good, the cock's comb lopping down over the eye more so than any bird's of like breed we ever met with; but the other competing pens were all of them very faulty in colour of plumage. It is really a pity so good a breed of poultry as the Silver-Grey

Dorkings should be so badly represented, for they are not only useful, but decidedly one of the most attractive varieties (when truly bred), of any of the *Dorking* family. The Coloured *Dorking* classes and the White ones made ample amends for previous shortcomings. It is hopeless to wish for better than the Coloured exhibited by Viscountess Holmesdale, which were rosy-combed ones, and yet by no means of coarse character. The great fault of the White *Dorkings* arose from the monstrous deformities of the combs in the cocks; still, as before said, this breed of birds was at least equal to those formerly shown. It is essential for amateurs to see that the entries are perfectly correct, as at Manchester several pens of the best of the *Dorkings* were disqualified from being exhibited in the wrong classes.

The Black *Spanish* fowls, for which no less than six classes appeared in the Manchester prize schedule, were really a chief feature of the Show, and produced a large entry of the best of birds. Some of the hens, particularly, were of first-rate excellence.

In the *Cochin-China* classes for Cinnamon and Buffs, Capt. Heaton left a very slight sweeping of premiums for his rivals. This gentleman, it will be seen by reference to the prize list, secured no less than five first prizes out of the six offered for Buffs—a most extraordinary occurrence in these days for any one yard. The winners at the recent Show at Darlington are now added to Capt. Heaton's stock, so that with proper care and attention not only may he challenge present competition, but doubtless will be hard to beat in future years also, providing the proper mating of his immense stock for breeding purposes be judiciously carried out. Certain it is no one breeder has so many high-class Buff *Cochins* in his possession at the present moment as Capt. Heaton. The Brown and Partridge-coloured *Cochins* were of quite average merit and formed a good collection. The White *Cochins* were perfect, Messrs. Dawson and Whitwell showing such as would prove a pride to any meeting.

The *Brahmas* were not so good as hoped for, and the *Malay* classes were absolutely without a single entry in any of the four classes appropriated to them.

Some capital *Polands* were shown so far as only two pens were concerned, but the Polish did not muster even half a dozen pens in the whole.

The *Guine* classes have rarely been excelled, and the competition was great.

The *Hamburghs* were best among the Spangled varieties, the Pencilled not being so perfect in markings as they should be. The *Geese*, *Ducks*, and *Turkeys* were magnificent throughout.

In the class for ornamental water fowls, the proprietor of the gardens had a really well-filled class of entirely his own birds, and this class was one of the most attractive to sight-seers of any in the Show. Among them were admirably plumaged specimens of the *Beau*, *Barnacle*, and *Brent* *Geese*, and by no means less worthy *Carolina Ducks*, *Pintails*, *Widgeon*, *Teal*, *Shellbrakes* and *Cali Ducks*, yet the gardens themselves seemed still as well stocked as ever, the quantity kept by the Messrs. Jennison being beyond the credence of those who have not yet visited Belle Vue. As there was no competitor, Messrs. Jennison's prizes must literally have walked out of one pocket into the other.

The entries for *Turkeys* were small, but the quality was excellent.

The feeding and watering of the poultry was most methodically carried out, and the Manchester Show proved not to have lost interest. The show of *Pigeons* was better than any that has taken place before under the auspices of this Society.

DORKINGS (Silver Grey).—First, R. D. Holt. Second, J. K. Fowler. *Cock*.—First, F. H. Taylor. *Chickens*.—First, T. Slater. Second, R. D. Holt. Highly Commended, Lady Egout. *Cockerel*.—First, Lady Egout. Second, T. Slater. *Pullets*.—First, E. Leech. Second, J. Robinson. Commended, T. Slater.

DORKINGS (Coloured, except Silver Grey).—First, Viscountess Holmesdale. Second, Capt. Heaton. Highly Commended, Sir St. G. Gore, Bart. *Cock*.—First, J. Robinson. Second, C. Priest. Highly Commended, Mrs. F. S. Arkwright. Commended, A. Potts. *Hens*.—First, Sir St. G. Gore, Bart. Second, Miss S. J. Smith. Highly Commended, Mrs. T. T. C. Lister. *Chickens*.—First, Viscountess Holmesdale. Second, Capt. W. Hornby. Highly Commended, Sir St. G. Gore, Bart. Commended, Mrs. T. T. C. Lister. *Cockerel*.—First E. Tutman. Second C. Priest. Highly Commended, J. Smith; E. Shaw. Commended, Rev. E. Cadogan. *Pullets*.—Prize, C. Priest.

DORKINGS (White).—First, J. Robinson. Second, W. T. Everard. *Cock*—Prize, J. Robinson.

CREVE CURVE.—Prize, W. Blinkhorn, jun.

SPANISH.—First, Viscountess Holmesdale. Second, J. Garlick. Highly Commended, E. Brown. *Cock*.—First, Master J. T. Smith. Second, S. H. Hyde. Highly Commended, H. Lane; J. R. Rodbard. *Hens*.—First, H. Lane. Second, J. R. Rodbard. Highly Commended, S. H. Hyde; J. Smith. Commended, W. Cannon. *Chickens*.—First, J. Garlick. Second, D. Parsley. Third, Viscountess Holmesdale. Highly Commended, S. Robinson. Commended, J. Smith. *Cockerel*.—First, J. R. Rodbard. Second, J. L. Lowndes. Third, C. Cayford. Highly Commended, D. Parsley; H. C. Mobbs. Commended, H. Lane; J. Potter; J. Garlick. *Pullets*.—First, H. Lane. Second, J. Bigger. Commended, E. T. Holden; D. Parsley.

COCHIN-CHINA.—First, Capt. Heaton. Second, T. Stretch. Highly Commended, C. T. Bishop; G. Fell. Commended, E. Musgrove. *Cock*.—First, T. Stretch. Second, H. Bates. *Hens*.—First, Capt. Heaton. Second, R. Adams. Commended, C. T. Bishop; D. Caver. *Chickens*.—First, Capt. Heaton. Second, C. T. Bishop. *Cockerel*.—First, Capt. Heaton. Second, E. Musgrove. *Pullets*.—First, Capt. Heaton. Second, G. G. Gbert.

COCHIN-CHINA (Brown and Partridge-feathered).—First, T. Stretch. Second, E. Tudman. *Cock*.—First, T. Stretch. *Hens*.—First, E. Smith. Second, E. T. Holden. *Chickens*.—First, E. Tudman. Second, T. Stretch. *Cockerel*.—First, J. Shortrose. Second, J. Wright. Highly Commended, Master W. H. Kershaw. *Pullets*.—First, C. Kershaw. Second, J. B. Whitew.

COCHIN-CHINA (White).—First, W. Dawson. Second, G. C. Whitwell. Highly Commended, R. Chase. *Cock*.—Prize, J. Bigger. *Chickens*.—Prize, R. Chase. *Cockerel*.—Prize, J. Bigger.

BRAMA POOTRA.—First, H. Lacy. Second, C. Priest. *Cock*.—Prize, J. Pares. *Chickens*.—First, H. Lacy. Second, M. Hedley. *Cockerel*.—First, C. Priest. Second, J. Wright.

POLISH (Black with White Crests).—*Cock*.—Prize, J. Smith. *Chickens*.—Prize, J. Smith.

POLISH (Silver).—*Cock*.—Prize, J. Heath.

HAMBURG (Golden-pencilled).—First, J. E. Powers. Second, J. Neville. *Chickens*.—First and Second, T. H. Ashton. Third, Captain Pares. *Cockerel*.—First, N. Barter. Second, W. Kershaw.

HAMBURG (Silver-spangled).—First, Right Hon. Viscountess Holmesdale. Second, J. Robinson. *Chickens*.—First, Right Hon. Viscountess Holmesdale. Second, C. M. Ryds. Highly Commended, J. Robinson. *Cockerel*.—First, J. Robinson. Second, T. W. Walsh.

HAMBURG (Hens) (Pencilled).—Prize, C. W. Brierley. *Pullets*.—First, Rev. T. L. Fellows. Second, W. Rothwell. Highly Commended, J. Morris.

HAMBURG (Golden-spangled).—First, J. Robinson. Second, I. Davies. *Cock*.—First, H. W. B. Erwick. Second, G. Brook. *Chickens*.—First, N. Marler. Second, C. Broadbent. *Cockerel*.—First, S. H. Hyde. Second, W. Kershaw.

HAMBURG (Silver-spangled).—First, W. Cannon. Second, T. Dale. *Cock*.—First and Second, W. Stephens. *Chickens*.—First, Right Hon. Viscountess Holmesdale. Second, T. H. Ashton. Commended, J. Robinson. *Cockerel*.—First, W. Hargreaves. Second, P. Saindels. *Hens*.—First, Rev. W. S. Johnston. Second, H. W. B. Erwick.

HAMBURG (Spangled).—First, W. W. Nicholls. Second, Rev. T. L. Fellows.

GAME (Black-breasted Reds).—First, S. Matthew. Second, M. Billing, jun. Third, Mrs. Hay. Highly Commended, F. Sales. *Cock*.—First, C. Chaloner. Second, H. M. Julian. Third, J. J. Cranidge. Highly Commended, J. Sundeland, jun.; M. Billing, jun. Commended, R. Hower. *Chickens*.—First, M. Billing, jun. Second, W. T. Everard. Third, J. Halsall. Commended, R. Parkinson; C. Stubbs. *Cockerel*.—First, M. Billing, jun. Second, J. Stubbs.

GAME (Brown and other Reds, except Black-breasted).—First, T. Robinson. Second, H. Adams. *Cock*.—First, C. Chaloner. Second, W. Boyes. Third, W. Whitwell. Highly Commended, M. Billing, jun. Commended, T. Statter; M. Billing, jun. *Chickens*.—First, Mrs. Hay. Second, W. Copple. Third, W. Whitwell. Highly Commended, S. Matthew; T. Statter. Mrs. E. Bennett. Commended, J. Wood. *Cockerel*.—First, E. Bowles. Second, T. Statter. Commended, J. Wood.

GAME (Hens).—First, W. Boyes. Second, H. Adams. Highly Commended, A. Woods; E. Aykroyd; M. Billing, jun. *Pullet*.—First, C. W. Brierley. Second, G. Clements. Third, M. Billing, jun. Highly Commended, E. Aykroyd; Mrs. S. J. Whitlam; G. Clements. Commended, T. W. Redhead.

GAME (Duckwings and other Greys and Blues).—First, S. Matthew. Second, W. Boyes. Commended, H. Adams. *Chickens*.—First, J. Halsall. Second, W. T. Everard. Third, E. Aykroyd. Highly Commended, J. Holme.

GAME (except Black-breasted and other Reds).—First, E. Aykroyd. Second, M. Billing, jun. Highly Commended, H. Adams; E. Needham. *Chickens*.—First, W. T. Everard. Second, M. Billing, jun.

GAME (Black and Brassy-winged, except Greys).—Prize, M. Billing, jun. *Chickens*.—Prize, H. M. Julian.

GAME (White and Fies).—First, M. Billing, jun. Second, T. West. Highly Commended, S. Matthew; H. Adams. Commended, Mrs. S. J. Whitlam. *Chickens*.—First, T. West. Second, M. Billing, jun.

GAME (Hens) (except Black-breasted and other Reds).—First, H. Adams. Second, J. Goodwin. *Chickens*.—First, T. West. Second, W. T. Everard.

GAME BANTAMS (black-breasted and other Reds).—First, E. W. Crawford. Second, Sir St. G. Gore, Bart. Third, J. Munn. Highly Commended, E. Musgrove. Commended, C. Martin.

GAME BANTAMS (Any other variety).—Prize, C. W. Brierley. *Pullets*.—First, E. A. Crawford. Second, J. Garlick.

GAME BANTAM COCK.—First, C. W. Brierley. Second, E. Musgrove. *Cockerel*.—First, J. W. Morris. Second, J. Shortrose.

BANTAMS (Silver-laced).—Prize, R. Chase. *Chickens*.—Prize, J. W. Morris.

BANTAMS (White, Clean-legged).—Prize, F. Marten. *Chickens*.—Prize, Sir St. G. Gore, Bart.

BANTAMS (Black, Clean-legged).—Prize, Miss K. Charlton. *Chickens*.—First, Miss K. Charlton. Second, Mrs. F. Huxey-Freke.

BANTAMS (Any other variety).—Prize, F. Marten.

BANTAMS (except Game Bantams).—Prize, C. W. Brierley.

DUCKS (White Aylesbury).—First, Sir St. G. Gore, Bart. Second, J. K. Fowler. Highly Commended, J. Pratt; J. Smith. Commended, J. K. Fowler.

DUCKS (Ronen).—First, S. Shaw. Second, W. Copple. Third, J. Holme. **DUCKS (Black East Indian).**—First, F. W. Earle. Second, J. R. Jessop. **DUCKS (Any other variety).**—First, C. P. Ackers. Second, T. Wakefield. **ORNAMENTAL WATER FOWLS.**—First, Second, Third, Highly Commended, and Commended, J. Jennison.

GESE (White).—First, W. Kershaw. Second, J. Southern. Highly Commended, J. K. Fowler. Commended, J. Brundrett, jun.

GESE (Grey and Mottled).—First, J. K. Fowler. Second, J. Southern.

TURKEYS.—Prize, J. Smith. Commended, Mrs. E. Skerrett. *Pouls*.—First, J. W. Smith. Second, Rev. W. Serjeantson. Highly Commended, Mrs. E. Skerrett. Commended, J. Smith.

EXTRA STOCK.—First, R. F. Goodwin (Black Hamburg). Second, W. Nichols (Black Hamburg).

PIGEONS.

THE collection of Pigeons, although not numerous, was exceedingly choice. In *Pouters* Mr. Eden had a very easy victory with his fine Whites and Blues. *Carriers* were excellent, Messrs. Eden and Else taking all the prizes; the most noticeable being the Duns and wonderful Black cock of the former, and Mr. Else's remarkably fine Black Hen. In *Dragoons* good Blues were first and Yellows second. In *Jacobins* Mr. Esquilant was first with a very small fine pair of Reds; and Mr. Lawrence's excellent Yellows were second, reversing the late Birmingham decisions. In *Nuns* the Black-headed variety took the prize. In *Earls* Mr. Eden was first with a promising pair of young Blacks, and also received high commendations for a like pair. Mr. Sanday took second with Blacks also, one of which was so much affected in the head as to be out of place in an exhibition-pen, and unlikely to reach home alive. In *Turbits* Mr. Shaw had first with a good pair of Reds in splendid condition; Blues taking second. *Owls* formed one of the best classes in this department, good Whites taking both prizes. In *Trumpeters* Mr. Oates struggles manfully with his capital Whites, always well shown, but has to succumb to Mr. Shaw's magnificent Black Mottles whenever they put in an appearance. As on many previous occasions the above-named again occupied the respective positions of first and second; and Mr. Shaw has reason to be proud of his really wonderful pair. In *Fantails* it seems to be the humour of the "ruling powers" to prefer Crested birds. A short time ago this variety merely received "high commendation as Indians." The present instance was no exception to late decisions. No doubt they were excellent in tail, but the smallness, extraordinary grace, and symmetry of some of the Smooth-headed kind is wanting. In *Almond Tumblers* the late Birmingham decisions were reversed, Mr. Eden having both prizes, while Mr. Else's were very highly commended. The second-prize pen were rather unevenly matched, though good in other respects. *Bolds* were good, Mr. Esquilant having both prizes with Blues. In *Beards* Messrs. Fielding and Esquilant divided the prizes with fine Blues. Any other *Variety Tumblers* was a good class, both prizes being awarded to Mr. Eden's very fine Black Mottles. In *Any other new or distinct breed*, Mr. Yardley added another to his list of prizes with his well-known Satinettes; a beautiful pair of Isabels taking second, and Hyacinths were commended. A pair of Black-tailed Owls were again tried in this class, and were passed over unnoticed. It would seem that the Arbitrator coincides with our remarks on the Birmingham Show—that the birds in question are improperly classified.

POUTERS.—First and Second, P. Eden.

CARRIERS (Black) Cock.—First, P. Eden. Second, F. Else. Very Highly Commended, J. Wadsworth; P. Eden. *Cock of any other Colour.*—Prize, P. Eden. *Hen (Black).*—First, F. Else. Second and Highly Commended, P. Eden. *Hen of any other Colour.*—Prize, P. Eden. Commended, J. Fifth.

DRAGONS.—First, J. Percival. Second, F. Esquilant. Commended, J. Wadsworth; F. Mignall.

JACOBS.—First, F. Esquilant. Second, J. T. Lawrence.

NUNS.—Prize, T. Rudolph.

BEARDS.—First, P. Eden. Second, G. H. Sanday. Highly Commended, P. Eden. Commended, S. Shaw.

TURBITS.—First, S. Shaw. Second, H. Magson. Commended, M. E. John.

OWLS.—First, J. Fielding, jun. Second, G. H. Sanday. Commended, H. Yardley.

TRUMPETERS.—First, S. Shaw. Second, W. H. C. Oates.

FANTAILS.—First, H. Yardley. Second, J. W. Edge. Commended, T. Rudolph.

ALMOND TUMBLERS.—First and Second, P. Eden. Very Highly Commended, F. Else.

BOLDS.—First and Second, F. Esquilant.

TUMBLERS (Any other variety).—First and Second, P. Eden. Commended, W. Wadsworth; J. Fielding, jun.

BEARDS.—First, J. Fielding, jun. Second, F. Esquilant.

ANY OTHER NEW OR DISTINCT VARIETY.—First, H. Yardley (Satinettes). Second, the Countess of Derby (Isabels). Commended, J. Chetham (Hyacinths).

RABBITS.—*Black and White*.—Prize, G. F. Greensill. *Yellow and White*.—First, G. Wood. Second, R. I. Anson. *Tortoiseshell*.—First, G. F. Greensill. Second, H. Handford. *Blue and White*.—Prize, G. South, jun. *Grey and White*.—First, H. Handford. Second, A. Fifth. *Self Colour*.—Prize, G. Jones. *Longest Ears*.—Prize, R. I. Anson. *Foreign*.—Prize, J. Buchanan.

JUDGES.—*Poultry*: Dorking, Crève Cœur, Spanish, Cochon China, Brahma Pootra, Malay, and Polish Fowl—Mr. Hewitt, Birmingham; Mr. Teebay, Preston. *Hamburgh, Baxtam, Ducks, Geese, Turkeys, and Extra Stock*—Mr. Douglas, London; Mr. Leno, Dunstable. *Game*—Mr. Challoner, Chesterfield; Mr. Sutherland, Burnley. *Pigeons*: Dr. Cottle, Cheltenham. *Rabbits*: Mr. Owen, London.

SCOTTISH ORNITHOLOGICAL ASSOCIATION.

THE fifth annual Exhibition of Pigeons and Canary birds, under the auspices of this Association, was held on the 18th and 19th inst., at the Rifle Hall, Waterloo Street, corner of Pitt Street, Glasgow. The entries were numerous, there being no fewer than 400 pens of Pigeons, and 211 cages of Canary birds, numbering about 1000 head, and forming one of the finest exhibitions of the kind ever seen in this quarter. In the Pigeon department the competition was very keen, consequently upon the large number of excellent birds which were brought forward. The entries for the silver cup consisted of very beautiful birds, which were much admired. In the Powder class the entries were more numerous than on any previous occasion, and the Pigeons were in splendid condition; indeed, the competition in all the classes entered for medals was of a very keen description. The show of Carrier Pigeons, both old and young, was also good, many birds remarkable for their beauty being exhibited. In the other classes, including Short-faced Tumblers, there was an excellent display.

The entries of Canary birds were also more numerous than last year; and amongst the collection were many really pretty birds, whose forms were faultless. Amongst the Belgian Fancy were some splendid birds; and in this class the competition was exceedingly keen. The show of Piebalds and Goldfinch Mules was much admired, the collection containing many beautifully marked birds.

The following is the list of awards:—

PIGEONS.

POWTERS (Black Cocks).—First, H. Hawkins, Belfast. Second, R. Fulton, Deptford. Very Highly Commended, J. Miller, Glasgow. Highly Commended, M. Stuart, Glasgow. Commended, G. Ure, Dundee.

POWTERS (White Cocks).—First and Second, and Columbarian Medal, G. Ure, Dundee. Very Highly Commended, J. Wallace, Glasgow.

POWTERS (Blue Cocks).—First, R. Fulton, Deptford. Second, D. Stewart, Perth. Very Highly Commended, J. Miller, Glasgow. Highly Commended, J. H. Frame, Carlisle.

POWTERS (Red Cocks).—First, H. Hawkins, Belfast. Second, J. Ruthven, Glasgow. Very Highly Commended, J. H. Frame, Carlisle. Highly Commended, J. Wallace, Glasgow. Commended, H. Brown, Sheffield.

POWTERS (Yellow Cocks).—First, J. Ruthven, Glasgow. Second, G. Ure, Dundee.

POWTERS (Cock, Any other colour).—First, W. Lightbody, Glasgow. Second, J. Wallace, Glasgow.

POWTERS (Black Hens).—First, J. H. Frame, Carlisle. Second, G. Ure, Dundee.

POWTERS (White Hens).—First and Columbarian Medal, M. Sanderson, Edinburgh. Second, G. Ure, Dundee. Very Highly Commended, H. Hawkins, Belfast. Highly Commended, G. Ure, Dundee.

POWTERS (Blue Hens).—First, J. Cochran, Glasgow. Second, J. Ruthven, Glasgow. Very Highly Commended, G. Ure, Dundee. Highly Commended, H. Hawkins, Belfast.

POWTERS (Red Hens).—First, G. Ure, Dundee. Second, G. R. Potts, Sunderland. Very Highly Commended, W. Newton, Newark.

POWTERS (Yellow Hens).—First, G. Ure, Dundee. Second, J. Huie, Glasgow. Very Highly Commended, M. Stuart, Glasgow. Highly Commended, W. Newton, Newark.

POWTERS (Hen, Any other colour).—First, J. Muir, Glasgow. Second, J. Ruthven, Glasgow.

CARRIERS (Black Cocks).—First, G. Ure, Dundee. Second, T. Colley, Sheffield. Very Highly Commended, F. Colley. Highly Commended, H. Hawkins, Belfast.

CARRIERS (Dun Cocks).—First and Columbarian Medal, J. Wallace, Glasgow. Second, T. Colley, Sheffield.

CARRIERS (Black Hens).—First and Columbarian Medal, J. H. Frame, Carlisle. Second, T. Colley, Sheffield. Very Highly Commended, G. Ure, Dundee.

CARRIERS (Dun Hens).—First, H. Holman, Plymouth. Second, F. Else, London. Very Highly Commended, T. Short, Glasgow. Highly Commended, T. Colley, Sheffield. Commended, H. Hawkins, Belfast.

SHORT-FACED NOTTLED TUMBLERS (Any colour).—First, G. Ure, Dundee. Second, H. Martin, Glasgow. Very Highly Commended, J. Wallace, Glasgow.

SHORT-FACED TUMBLERS (Any other colour or variety).—First and Second, M. Stuart, Glasgow. Very Highly Commended, M. Stuart. Highly Commended, R. Fulton, Deptford.

ALMOND TUMBLERS (Short-faced).—First and Columbarian Medal, M.

Stuart, Glasgow. Second, G. Ure, Dundee. Very Highly Commended, J. Montgomery, Belfast. Highly Commended, J. Wallace, Glasgow. Commended, M. Stuart.

BAKES (Cocks).—First and Second, J. H. Frame, Carlisle.

BAKES (Hens).—First and Second, J. H. Frame, Carlisle. Very Highly Commended, J. R. Rennards, Helensburgh.

FANTAILS.—First and Silver Medal, H. Beldon, Bingley. Very Highly Commended, J. R. Jessop, Dulai.

FANTAILS.—First, G. Ure, Dundee. Second, J. L. Irvine. Very Highly Commended, R. Trench, sen, Paisley.

JACOBS.—First, R. Pickering, Carlisle. Second, J. Sharp, Johnstone. Very Highly Commended, T. Short, Glasgow. Highly Commended, J. A. G. Chalmers, Glasgow.

TRUMPETERS.—First, L. M. Ewart, Belfast. Second, H. Yardley, Birmingham. Very Highly Commended, F. Key, Beverley.

TURBIDS.—First, H. Yardley, Birmingham. Second, J. R. Rennards, Helensburgh. Very Highly Commended, F. Key, Beverley.

OWLS.—First, H. Beldon, Bingley. Second, J. Fielding, Rochdale. Very Highly Commended, J. H. Frame, Carlisle. Highly Commended, H. Yardley, Birmingham. Commended, R. Pickering, Carlisle.

NUNS.—First, F. Key, Beverley. Second, D. Gray, Kibbarchan. Very Highly Commended, H. Yardley, Birmingham.

MAPIES.—First, J. Perera, Puckham. Second, L. M. Ewart, Belfast. Very Highly Commended, T. Short, Glasgow.

TUMBLERS (Common).—First, A. Morrison, Glasgow. Second, M. E. Jobling, Newcastle-on-Tyne. Third, W. Weir, Glasgow. Very Highly Commended, R. Pickering, Carlisle. Highly Commended, J. Fielding, Rochdale.

OTHER BREEDS.—First, J. Huie, Glasgow. Second, G. Ure, Dundee. Third, M. E. Jobling, Newcastle-on-Tyne. Very Highly Commended, M. E. Jobling. Highly Commended, G. Jeffrey, Edinburgh. Commended, J. Ruthven, Glasgow.

EXTRA PRIZES.

Three pens Fantails, Jacobs, Trumpeters, Turbids, Owls, Nuns, and Mapiers.—First Silver Cup, G. Ure, Dundee. Very Highly Commended, J. R. Rennards, Helensburgh. Highly Commended, F. Else, London. Commended, J. H. Frame, Carlisle.

POWTERS (Black).—First (Silver Medal), G. Ure, Dundee. Very Highly Commended, G. Jeffrey, Edinburgh. Highly Commended, T. Short, Glasgow.

POWTERS (White).—First (Silver Medal), G. Ure, Dundee. Very Highly Commended, M. Sanderson, Edinburgh. Highly Commended, G. Ure, Dundee.

POWTERS (Blue).—First (Silver Medal), M. Stuart, Glasgow. Very Highly Commended, G. Ure, Dundee. Highly Commended, J. Miller, Glasgow.

CARRIERS (Any colour).—First (Silver Medal), H. Hawkins, Belfast. Very Highly Commended, G. Ure, Dundee. Highly Commended, R. Pickering, Carlisle.

ALMOND TUMBLERS (Short-faced).—First (Silver Medal), M. Stuart, Glasgow. Very Highly Commended, J. Crawford, Glasgow.

BAKES (Any colour).—First (Silver Medal), J. H. Frame, Carlisle. Very Highly Commended, M. Stuart, Perth. Highly Commended, M. E. Jobling, Newcastle-on-Tyne. Commended, P. H. Jones, London.

CANARIES.

Pair Scotch Honey, the produce of 1867, or prior thereto.—First (handsome piece of silver plate); and, Second, G. Masterton, Glasgow.

SCOTCH FANCY.

YELLOW COCKS.—First, T. Buchanan, Glasgow. Second, A. Wilson, Wishaw. Third, S. Brown, Glasgow. Fourth, W. McLeod, Glasgow.

BUFF COCKS.—First, G. Aytton, Glasgow. Second, J. Mitchell, Perth. Third, G. Bunnie, Perth. Fourth, D. Stewart, Perth.

YELLOW HENS.—First, A. Wilson, Wishaw. Second, G. Masterton, Glasgow. Third, W. Ferguson, Beith. Fourth, R. McMillan, Stevenston.

BUFF HENS.—First, D. Johnstone, Glasgow. Second, J. McGill, Edinburgh. Third, J. Kerr, Perth. Fourth, W. Thom, Stevenston.

BELOGAN FANCY.

YELLOW COCKS.—First, R. Forsyth, Edinburgh. Second, T. Haddow, Glasgow. Third, J. Ruthven, Glasgow.

BUFF COCKS.—First, J. Huie, Glasgow. Second, W. Forrest, Edinburgh. Third, J. Edington, Leith.

YELLOW HENS.—First, Mrs. Clark, Glasgow. Second, J. Beeby, Carlisle. Third, J. Henderson, Kendal.

BUFF HENS.—First and Second, J. Huie, Glasgow. Third, R. Ruthven, Glasgow.

PIEBALDS.

YELLOW COCKS.—First, C. McWilliams, Glasgow. Second, H. Fisher, Glasgow. Third, W. Wilson, Mauchline.

BUFF COCKS.—First, A. Wilson, Wishaw. Second, J. Johnston, Glasgow. Third, N. McLean, Glasgow.

YELLOW HENS.—First, T. Law, Newarhill. Second, J. Fulton, Beith. Third, H. Newall, Glasgow.

BUFF HENS.—First, J. Binning, Hamilton. Second, J. Armstrong, Glasgow. Third, R. White, Paisley.

GOLDFINCH MULES.

YELLOW COCKS.—First, W. Kirk, Dunfermline. Second, J. Hamilton. Third, W. Kirk, Dunfermline.

BUFF COCKS.—First, T. Buchanan, Glasgow. Second, W. Kirk, Dunfermline.

GOLDFINCHES.

First, T. Adam, Paisley. Second, R. Paterson, Glasgow. Third, G. Hamilton, Hamilton.

The following gentlemen officiated as Judges:—For *Pigeons*: E. L. Corker, Esq., Croydon, Surrey; and D. Wolstenholme, Esq., Gray's Inn Road, London. For *Canaries*: Messrs. James Graham, Kilmarnock; Thomas Pate, Beith; Robert Crawford, Kilmarnock; George Masterton, Thos. Haddow, and George Horsburgh, Glasgow.

MIDLAND COUNTIES BIRD SHOW.—It will be seen on reference to our advertising columns that it is contemplated

holding an exhibition of Canaries, British and Foreign Birds, &c., at the Mechanics' Hall, Derby, on the 15th and 16th of next month. Derby, there can be little doubt, presents facilities for such an exhibition second to none in the kingdom, as it enjoys railway communication with all parts and is pretty centrally situated.

MR. ALFRED HEATH'S ISABEL POWTERS.

BEING last week on a visit near Calne, I inquired for the residence of Mr. Alfred Heath; for having read in this Journal an account of his Isabels or Isabel Powters, I had a curiosity to see the same. I fortunately found Mr. Heath at home; he most readily and kindly showed me his birds, and I spent some time very pleasantly (for in the country a pigeon-fancier seldom meets with a brother), in examining the whole of his stock.

In regard to the Isabels, there can be no doubt that they are Powters. As one pair was recently sold by Mr. Stevens, Mr. Brent if not the buyer, probably saw them, and was confirmed in his opinion that they are Powters, as undoubtedly they are, and nothing less or more. They have a very refined and delicate look, and I could not, when seeing them, sever from my mind the idea of the Collared Turtle Dove (*Columbarisoria*), possibly this arose from their colour only. They also struck me as being admirably suited for an aviary, or where birds are kept confined, being just the Pigeons to be ladies' pets, and the nearer view you get of them the prettier they are, their elegant cream colour, to be fully appreciated, demanding a close inspection. The very full development of the crop in the hen is worth notice, and the thoroughly feathered state of their legs. On the whole, prettier, more slender-shaped, and more elegant Pigeons I never saw, and though Powters, yet among a number of those birds my eye fell upon them at once, for beauties of their own. Their frequently producing white or nearly white young ones, looks, I fancy, as if they were originally bred from a white Powder and another Pigeon, could it be the *Columbarisoria*? I once saw a young bird, but which died, bred from a hen Dove and a very small high-bred Tumbler. I believe this was the case, a schoolfellow possessed the birds and I was frequently his playmate and recollect seeing all three. After, therefore, a careful examination, I would certainly say that the Isabel Powder is a gain to our varieties of Pigeons.

One word more. We know how very small difficulties become when a man is in earnest in a pursuit or hobby. I have heard of such a man saying, "Sir, I never spell difficulty with a great D." And Spitalfields weavers with their valuable Tumblers, and Lancashire cotton operatives with their stands of fine Auriculas, show that men in pursuing recreations can make much out of scanty means. Here was Mr. Heath with a small square yard, with high buildings around—for Calne is an old-fashioned town with the streets narrow and the houses near together—yet in this small yard he manages to have on the south side, a capitally arranged pigeon-loft on the ground floor, full of valuable birds on the separate box system, each box capable of being closed, and all the birds having their freedom; there is a covered run on another side for Spanish fowls, a fountain in the middle, and a little shallow bit of clean water on the Pigeon side with its tiny jet, for the Pigeons to bathe in—and all, Pigeons and fowls, looking healthy. How Mr. Heath manages to prevent depredations from cats I cannot conceive, with such capital cat promenades all round him. Who can estimate the innocent enjoyment, in the hours of leisure from business, which that small yard and its inhabitants afford Mr. Heath? —WILTSHIRE RECTOR.

POLLEN-GATHERING AND BEES BREEDING IN DECEMBER.

—As a proof of the mildness of the winter, I may mention the following fact. Having occasion on the afternoon of Saturday, the 19th inst., to examine the roots of a wall tree immediately behind one of my hives (a Stewarton), to prevent annoyance from the bees, I ran in the sliding-door. Shortly thereafter I observed three foragers on the board anxiously awaiting admittance; and to my surprise, in each case their thigh-baskets were sparingly laden with dark-

coloured pollen, similar to what I was enabled to report collected in the end of January in the three last seasons.

While surveying the ravages of foul brood in another stock on the 17th inst., I noticed a sprinkling of newly-laid eggs. Neither hive was excited by feeding; the former was set on a ventilating eke. Fruit-buds on young pyramid pears are beginning to expand.—A KENFREWSHIRE BEE-KEEPER.

UNITING BEES.

HAVING given full particulars in page 423, of what I have found the best mode of driving a stock of bees and securing its queen, I now come to the means to be adopted for uniting the expelled workers to another colony.

If the bees to which they are to be united are domiciled in a common hive, I know no better means of effecting the desired object than that described in page 59 of the last edition of "Bee-keeping for the Many"—viz., about an hour after sunset to spread a cloth on the ground opposite the stock to which the bees are to be joined, on which cloth two sticks must be laid about 8 inches apart, then with a smart stroke dash out the bees between the sticks, and instantly, but very gently, place the stock they are intended to enter upon the sticks, leave them for the night, having first defended them from rain, should any fall, and in the morning an hour before sunrise replace the stock in its original position, and all will be peace and harmony.

Thus far Mr. Payne, and he may be, and probably will be found to be right in a majority of cases; but in many instances I have known daylight reveal a sickening scene of slaughter, so extensive as to make it more than doubtful if sufficient bees survived to render the attempted union of the slightest advantage to the stock intended to be benefited thereby.

In order to diminish as much as possible the risk of such an unwelcome catastrophe, it is a good plan to treat both parties to a copious sprinkling of sugared water scented with peppermint, which is easily prepared by means of a little ordinary peppermint water added to simple syrup. This acts as a peacemaker in a double capacity—first, by confusing their sense of smell, and by this means rendering it more difficult for them to identify one another; and, secondly, by inducing the probable belligerents to gorge themselves with food, in which state "peace at any price" is their general maxim.

When, on the other hand, the destitute family is to be united to one domiciled in either a bar or a frame-hive, I confine them towards evening by tying them up securely in a cloth, and convey them in-doors for the night. In the forenoon, or towards the middle of the next day, I remove the crown-board of the hive to which they are to be added, and temporarily deepen it above the bars by laying on it a wooden frame of the same diameter as the hive, 1 to 1½ inch in depth. This done I replace the crown-board, blow a few whiffs of smoke under it, and proceed to loosen the knots of the cloth and cord by which the expatriated unfortunates are confined. All being ready, the crown-board is once more removed, and the bees treated to a liberal dose of the scented syrup. Almost at the same moment the restraining cloth is removed from the straw hive, and a few whiffs of smoke blown on the bees clustered within. This is followed by inverting the hive, and sprinkling the cluster with scented syrup. The next instant the entire cluster is dashed on the top of the exposed bars of their new domicile, and the crown-board being replaced before the cluster has time to spread, or many bees to take wing, the junction is effected in far less time than it has taken to describe the mode in which it is managed.

When both colonies are lodged in either bar or frame-hives of similar construction in the same apiary, I remove so many combs from the sides in such hive as to reduce them to one-half their original number, looking over the remaining combs one by one so as to assure myself of the existence of a queen in one case, and removing her entirely in the other.* These objects having been attained, the remaining combs and bees of the queenless stock are lifted out and placed on

*She may be kept alive a few days in order to provide against accident, by being placed with a few of her subjects and a bit of honeycomb or barley-sugar in a small perforated box, or under a wine-glass slightly raised on one side to admit air, and kept in a warm room.

each side of the combs in the other hive; stragglers having been brushed out on the top of the exposed bars, the crown-board may be replaced, and the job is complete. The use of smoke and scented syrup is an additional safeguard against a quarrel; but as the bees usually gorge themselves with honey during the preliminary examination and removal of a moiety of the combs, I generally omit these precautions, and seldom have reason to regret the omission.

All these modes of effecting autumnal unions have been fully tested, and may be relied upon as being effectual in the great majority of cases. An occasional quarrel may sometimes arise, and it is probable that with such pugnacious and bellicose insects no mode that can be devised will entirely obviate the possibility of such a *contre temps*. When it is desired to unite common to Ligurian bees the risk is considerably increased. Still, even this may be successfully effected in the great majority of cases, if all those precautions are adopted which have been indicated by—A DEVONSHIRE BEE-KEEPER.

BEE-FLOWERS.

I CAN confirm the observations of "A RENFREWSHIRE BEE-KEEPER," that the value of *Melilotus leucantha* as a bee-flower is very much over-estimated by some writers. I had some for several years, and found that the bees frequented it so little that I discontinued growing it. Borage, on the contrary, the bees are so fond of that I have a succession of three crops during the season; the first I raise as early as possible, and the last is generally cut down with the frost, when about three parts of the flowers have come out. I also sow a succession of French poppies, which yield an immense quantity of farina, and also look very gay in the garden. On the 10th of October, my bees were so busy collecting farina from the poppies, that I counted eight bees on one flower at the same time. I never saw so many on one flower before. My bees were carrying farina into the hives on the 24th of November, which is some weeks later than the average of years.—WILLIAM CARE, *Clayton Bridge Apiary, Newton Heath, near Manchester.*

ACCLIMATISATION AT THE ANTIPODES.—The Acclimatisation Society of Victoria has fortunately met with very liberal support from the Government, and has been enabled to obtain a most valuable site in a reserve of 500 acres appropriated as the Royal Park. It is described as being well grassed and timbered, presenting an agreeable undulating surface, though somewhat bleak and exposed. To this spot the Society and its friends are enabled to take the animals and birds which they may import into the colony. In order to fit it for the reception of animals a sum of about £4000 has been expended. There are paddocks with sheds erected, into which the goats and llamas that feed about the park in the daytime are driven for shelter. In the 50 acres which are allotted to the Society ample arrangements have been made for dividing and classifying the live stock. Substantially-constructed cages contain pheasants and doves, and such class of birds, with shelter-cots in the centre. The water fowl have their ponds in which to disport themselves and an island on which to breed. The zebras, the elks, and the ostriches have their separate compartments; a system, in short, is provided even more complete than that which exists at the Zoological Gardens in the Regent's Park. What would, however, be a novelty, and, indeed, a matter of surprise to many persons in this country, is the care which is manifestly bestowed upon the protection of those small birds which are considered here as the general enemy of the gardener and farmer. There, sparrows, and rooks, and finches, and yellowhammers, and blackbirds, and thrushes, and linnets, and robin redbreasts, and a host of other familiar members of the feathered tribes have been brought together, and after resting from the fatigues of their voyage across the sea, they are set at liberty to breed in the country, and establish for their races a home among the wilds of Australia. The birds which have been set at liberty at the Botanical Gardens of Victoria up to the present time have been eighteen canaries, eighteen blackbirds, twenty-four thrushes, six Californian quails, sixty

English wild ducks, thirty-five Java sparrows, four English robins, eight turtle doves, and fifty minor birds. At another point there have been located five pheasants, six skylarks, six Californian quails, four thrushes, four blackbirds, one pair white swans; at Sandhurst, four pheasants, four skylarks, and four thrushes; at Yarra, six thrushes and four skylarks; and near Sydney, seven thrushes four skylarks and ten blackbirds. The stock on hand of beast, birds, and fishes is not only interesting, as showing the value which is set upon many things held as of little worth in this country, but is, moreover, highly creditable to the managers of the Society in the colony.—(*Australian and New Zealand Gazette.*)

HERBIVOROUS ANIMALS AMONG YEW.

I HAVE always found in regard to the danger of yew to cattle, sheep, and horses, that in a growing state it is harmless, but when cut and withering it has killed every animal that has eaten of it (as far as my experience goes), except a goat. The goat was with the heifers which died, but I cannot say positively that it ate the yew, though we always believed it did so.—J. M. S.

[There is a decided conflict of evidence on this point. Dr. Martyn in his edition of Miller's "Gardeners' Dictionary" says:—"Some intelligent persons assert that the branches of yews while green are not noxious; but among the number of cattle that we have known fall victims to this deadly food, not one has been found when it was opened but had a lump of green yew in its paunch."]

SEEING an article on the above in your Journal of the 15th December, page 471, recalls to my memory a fact to which I can fully bear testimony. Early in the spring of 1855, I was living at Stapleford Park, Leicestershire, the seat of the late Earl of Harborough, and in the end of January, or beginning of February, a very severe frost set in, and the deer walked over the ice to a small island in the lake which was planted with some very fine yew trees; and the consequence was, that in the course of two or three days more than one hundred head of deer were poisoned by browsing on the yew. This shows that the statement you have quoted from Gilpin is not correct, although it is very possible that the poisonous effects of the yew might act with more deadly effect in consequence of the deer being starved to eat it in large quantity.—H. GENT, *Lower Clapton.*

[This is very important evidence. Mr. Gilpin evidently doubted the statement that deer are not poisoned by browsing on the yew, for he introduces it with "as park-keepers say."]

SUBSTITUTES FOR HOLLY BERRIES.—In answer to a correspondent, you say that you know of no method of dyeing peas so as to make up for a deficiency of holly berries in winter decorations, and suggest that they should be dipped in melted sealing-wax. Here in Yorkshire we use glass beads similar to the enclosed, and a very good substitute they make. They may be purchased at the wholesale toyshops, and are generally sold at a low price by the ounce.—RUSTIC ROBIN.

[The beads sent are of glass, coated inside with melted red sealing-wax.]

OUR LETTER BOX.

TO BREEDERS OF PARTRIDGE COCHINS.—A few amateurs propose to raise by a subscription of a guinea each, subject to 10 per cent. reduction for expenses) a fund to be awarded at the next Birmingham Show, in one prize (cup or specie) to the best pen of chickens of the above breed. This prize is to be awarded to subscribers' birds only; the prize to go in accordance with the Birmingham prize list; but should not a subscriber's bird be in the Birmingham prize list, the Judges will be requested to award this prize. The subscription will close on the 1st of March next. Subscribers' names must be sent in on or before that date to E. Tindan, Esq., Ash Grove, Whitechurch, Salop, who has kindly consented to receive the same.

NEWPORT POULTRY SHOW.—In our notice of the main features of this Show, we inadvertently stated that Lady Holmesdale had taken three first and five second prizes besides commendations; whereas the prize list indicates Lady Holmesdale to have been awarded five first prizes, independently of the one for the best collection of Poultry, and the same number of second prizes, and one third prize; such success we need hardly say, is only obtained by that good management and perseverance which Lady Holmesdale has always shown in the condition of the fowls she has exhibited.
